ONE-HUNDRED-AND-THIRTY-EIGHTH SESSION, 1891-92.

SESSIONAL ARRANGEMENTS.

The First Meeting of the One Hundred and Thirty-eighth Session of the Society was held on Wednesday, the 18th November, when the Opening Address was delivered by the Attorney-General, M.P., Chairman of the Council. The following arrangements have been made for the four meetings before Christmas:—

November 18.—The Attorney-General, M.P., Chairman of the Council, Opening Address.

,, 25.—Prof. Silvanus P. Thompson, F.R.S., "Measurement of Lenses." Prof. Carey Foster, F.R.S., will preside.

December 2.—G. H. Robertson, F.C.S., "Secondary Batteries." W. H. Preece, F.R.S., will preside.

,, 9.—James Dredge, "The World's Fair at Chicago, 1893." The Attorney-General, M.P., will preside.

,, 16.—Prof. Vivian B. Lewes, "Spontaneous Ignition of Coal, and its Prevention."

For meetings after Christmas:—

E. PRICE EDWARDS, "Burning Oils for Lighthouses and Lightships."
T. PRIDGIN TEALE, "Dust, and How to Shut it Out."
GENERAL PITT RIVERS, "Typological Museums."
T. ANDERSON, "Iceland."
I. W. TONKS, "Artistic Treatment of Jewellery and Personal Ornament."
SIR WILLIAM WEDDERBURN, Bart., "Agricultural Banks for India."
F. W. EDRIDGE-GREEN, M.D., "The Scientific Value of Lovibond's Tintometer."
DR. J. AUGUSTUS VOELCKER, "The Agricultural Needs of India."
LORD LAMINGTON, "Travels in Indo-China."
WILLIAM MORRIS, M.A., "The Woodcuts of Gothic Books."
J. W. WILLIS BUND, "The Fisheries Department, its Position and Prospects."
CAXTAIN V. LOVETT CAMERON, R.N., "The Congo State."

FOREIGN AND COLONIAL SECTION.

The meetings of this Section will take place on the following Tuesday Afternoons, at Half past Four o'clock:—

January 19, February 16, March 15, April 5, 26, May 24.

INDIAN SECTION.

The meetings of this Section will take place on the following Thursday Afternoons, at Half-past Four o'clock:—

January 21, February 11, March 3, 24, April 28, May 19.

APPLIED ART SECTION.

The meetings of this Section will take place on the following Tuesday Evenings, at Eight o'clock:—

January 26, February 23, March 8, 29, April 12, May 17.

CANTOR LECTURES.

These lectures will be delivered on the following Monday Evenings, at Eight o'clock:—

A. P. LAURIE, M.A., "The Pigments and Vehicles of the Old Masters." Three Lectures.

LECTURE I.—NOVEMBER 30.—A brief account of fresco painting as described by Cennino Cennini, and of the preparation of panels, gesso work and gilding in the 15th century. Also a description of the preparation of gilt Spanish leather.

LECTURE II.—DECEMBER 7.—The pigments used in the 15th century, and their preparation and properties, with some account of the methods of painting.

LECTURE III.—DECEMBER 14.—The mediums used by the Old Masters, in tempera and oil painting. The preparation of the oils and varnishes, and the properties of the same.

PROF. GEORGE FORBES, F.R.S., "Developments of Electrical Distribution." Four Lectures.

January 25, February 1, 8, 15.

PROF. WILLIAM ROBINSON, M.E., "The Uses of Petroleum in Prime Movers." Four Lectures.

February 29, March 7, 14, 21.

BENNETT H. BROUGH, "Mine Surveying." Three Lectures.

March 28, April 4, 11.

DR. PERCY FRANKLAND, F.C.S., "Recent Contributions to the Chemistry and Bacteriology of the Fermentation Industries." Four Lectures.

May, 2, 9, 16, 23.

HOWARD LECTURES.

A Special Course of Six Lectures, under the Howard Bequest, will be delivered on the following Friday Evenings, at Eight o'clock:—

PROF. W. CAWTHORNE UNWIN, F.R.S., "The Development and Transmission of Power from Central Stations."

February 5, 12, 19, 26, March 4, 11.

JUVENILE LECTURES.

Two lectures, suitable for a juvenile audience, on "The Three States of Matter," will be delivered by Professor J. M. THOMSON, F.C.S., on Wednesday evenings, January 6 and 13, 1892, at 7 p.m.

CHICAGO EXHIBITION, 1893.

The Council of the Society has been appointed a Royal Commission for the Chicago Exhibition, 1893. All applications for space in the British Section, and all inquiries for information about the Exhibition, should be addressed to the Secretary of the Royal Commission, Society of Arts, Adelphi, W.C.

PROCEEDINGS OF THE SOCIETY.

CHARTER.—THE SOCIETY OF ARTS was founded in 1754, and incorporated by Roya Charter in 1847, for "The Encouragement of the Arts, Manufactures, and Commerce of the Country, by bestowing rewards for such productions, inventions, or improvements as tend to the employment of the poor, to the increase of trade, and to the riches and honour of the kingdom; and for meritorious works in the various departments of the Fine Arts; for Discoveries, Inventions, and Improvements in Agriculture, Chemistry Mechanics, Manufactures, and other useful Arts; for the application of such natural and artificial products, whether of Home, Colonial, of Foreign growth and manufacture, as may appear likely to afford fresh objects of industry, and to increase the trade of the realm by extending the sphere of British commerce; and generally to assist in the advancement, development, and practical application of every department of science in connection with the Arts, Manufactures, and Commerce of this country."

THE SESSION.—The Session commences in November, and ends in June. The number of Meetings held during the Session amounts to between 70 and 80.

ORDINARY MEETINGS.—At the Wednesday Evening Meetings during the Session papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed.

INDIAN SECTION.—This Section was established in 1869, for the discussion of subjects connected with our Indian Empire. Six or more Meetings are held during the Session.

FOREIGN AND COLONIAL SECTION.—This Section was formed in 1874, under the title of the African Section, for the discussion of subjects connected with the Continent of Africa. It was enlarged in 1879, so as to include the consideration of subjects connected with our Colonies and Dependencies, and with Foreign Countries. Six or more Meetings are held during the Session.

APPLIED ART SECTION.—This Section was formed in 1886 for the discussion of subjects connected with the industrial applications of the Fine Arts. Six or more meetings are held during the Session.

CANTOR LECTURES.—These Lectures originated in 1863, with a bequest by the late Dr. Cantor. There are several Courses every Session, and each course consists generally of two or more Lectures.

ADDITIONAL LECTURES.—Special Courses of Lectures are occasionally given.

Juvenile Lectures.—A short Course of Lectures, suited for a Juvenile audience, is delivered to the Children of Members during the Christmas Holidays.

Admission to Meetings.—Members have the right of attending the above Meetings and Lectures. They require no tickets, but are admitted on signing their names. Every Member can admit *two* friends to the Ordinary and Sectional Meetings, and *one* friend to the Cantor and other Lectures. Books of tickets for the purpose are supplied to the Members, but admission can be obtained on the personal introduction of a Member. For the Juvenile Lectures special tickets are issued.

Journal of the Society of Arts.—The *Journal*, which is sent free to Members, is published weekly, and contains full Reports of all the Society's Proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce.

Examinations.—Examinations are held annually by the Society, through the agency of Local Committees, at various centres in the country. They are open to any person. The subjects include the principal divisions of a Commercial Education, Domestic Economy, and Music. A Programme, containing detailed information about the Examinations, can be had on application to the Secretary.

Library and Reading-room.—The Library and Reading-room are open to Members, who are also entitled to borrow books.

Conversazioni are held, to which the Members are invited, each Member receiving a card for himself and a Lady.

MEMBERSHIP.

The Society numbers at present between three and four thousand Members. The Annual Subscription is Two Guineas, payable in advance, and dates from the quarter-day preceding election; or a Life Subscription of Twenty Guineas may be paid.

Every Member whose subscription is not in arrear is entitled:—

To be present at the Evening Meetings of the Society, and to introduce two visitors at such meetings, subject to such special arrangements as the Council may deem necessary to be made from time to time.

To be present and vote at all General Meetings of the Society.

To be present at the Cantor and other Lectures, and to introduce one visitor.

To have personal free admissions to all Exhibitions held by the Society at its house in the Adelphi.

To be present at all the Society's *Conversazioni.*

To receive a copy of the Weekly *Journal* published by the Society.

To the use of the Library and Reading-room.

Candidates for Membership are proposed by three Members, one of whom, at least, must sign on personal knowledge; or are nominated by the Council.

All subscriptions should be paid to the Secretary, Sir Henry Trueman Wood, and all Cheques or Post-office Orders should be crossed "Coutts and Company," and forwarded to him at the Society's House, John-street, Adelphi, London, W.C.

HENRY TRUEMAN WOOD, *Secretary.*

CALENDAR FOR THE SESSION.

The chair will be taken at Eight o'clock at each of the Ordinary Meetings, the Cantor Lectures, Howard Lectures, and the Meetings of the Applied Art Section.

The Meetings of the Indian and the Foreign and Colonial Sections will commence at Half-past Four o'clock.

The Annual General Meeting will be held at Four o'clock.

The Juvenile Lectures will be given at Seven o'clock.

Chicago Exhibition, 1893.

A meeting of the Royal Commission was held on Wednesday, November 19. Present: The Attorney-General, M.P., in the chair; Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D.; Sir Frederick Bramwell, Bart., D.C.L., F.R.S.; Major-General Sir Owen Tudor Burne, K.C.S.I., C.I.E.; Michael Carteighe; B. Francis Cobb; Sir Philip Cunliffe-Owen, K.C.B, K.C.M.G., C.I.E.; Prof. James Dewar, M.A., F.R.S.; Major-General J. F. D. Donnelly, C.B.; James Dredge; Francis Elgar, LL.D.; Thomas Hawksley, F.R.S.; A. B. W. Kennedy, F.R.S.; C. M. Kennedy, C.B.; John Biddulph Martin; J. Fletcher Moulton, Q.C., F.R.S.; General the Rt. Hon. Sir Henry F. Ponsonby, G.C.B.; Wyndham S. Portal; W. H. Preece, F.R.S.; Prof. W. C. Roberts-Austen, C.B., F.R.S.; Sir Saul Samuel, K.C.M.G., C.B.; with Sir Henry Trueman Wood, Secretary.

APPLICATIONS FOR SPACE IN THE BRITISH SECTION.

The Royal Commission are now prepared to receive applications from manufacturers and others desirous of taking part in the Exhibition.

Such applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, not later than February 29th, 1892, and addressed to the Secretary, as above.

A prospectus giving particulars of charges for space and further information can be obtained at the Society's offices.

Proceedings of the Society.

FIRST ORDINARY MEETING.

Wednesday, November 18, 1891; the Attorney-General, M.P., Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Adams, Prof. Henry, 60, Queen Victoria-street, E.C.
Allen, James Mason, 11, Gray's-inn-square, W.C.
Allport, William, 36, Southampton-st., Strand, W.C.
Angelo, Elliott, Oriental Club, Hanover-square, W.
Askwith, George Ranken, 119, St. George's-square, S.W.
Barnwell, Richard, Fairfield-works, Govan, near Glasgow.
Basing, Lord, Hoddington-house, Winchfield, Hants.
Beck, William, jun., 3, Glebe-place, Stoke Newington, N.
Bingley, F. S. Norman, M.A., Inner Temple, E.C., and Conservative Club, S.W.
Bisset, James, Corsee-house, Banchory, N.B.
Brevetor, Ernest Frederick, Laburnums, Grove-lane, Stamford-hill, N.
Brown, Frederick Gordon, 17, Finsbury-circus, E.C.
Bury, Henry, M.A., 5, Palace Court-mansions, Bayswater, W.
Cane, Arthur, Spring-vale, Bush-hill-park, Enfield.
Cawston, George, Ascot Wood-house, Ascot
Chandler, Frederick L., Lloyd's, Royal Exchange, E.C.
Cheetham, Howard, Carlton-chambers, 18, St. Ann's-street, Manchester.
Child, Gilbert William, M.A., J.P., Cowley-house, Oxford.
Cleeves, Frederick, East-hill, Rotherham, Yorks.
Copland, William Wallace, The Waterworks, Sheerness.
Corthell, E. L., 205, La Salle-street, Chicago, Illinois, U.S.A.
Cruwys, Robert, 465, Brixton-road, S.W.
Cutler, Thomas William, 5, Queen-square, W.C.
Danson, John Towne, Grasmere, Westmoreland.
Dent, Rev. Charles, 76, Westbourne-terrace, W.
Donald, James, 92, Anerley-park, S.E.
Elwes, Henry John, Preston-house, Cirencester.
Finnemore, Robert Isaac, J.P., Durban, Natal, South Africa.
Fox, Charles, Roslin, Rectory-road, Beckenham, Kent.
Franklin, Henry Abraham, 14, St. Quintin-avenue, North Kensington, W.
Frost, Robert, B.Sc., 8, King's Bench-walk, E.C., and 42, Duke-street, St. James's, S.W.
Gouraud, Col., Little Menlo, Beulah-hill, S.E.
Graves, Walter, Winchester-house, Old Broad-street, E.C.
Greaves, Joseph Edward Elsworth, Engineering School and School of Science and Art, Rochdale, Lancashire.
Grice, Tom Edmund, Belle-vue, Tonbridge, Kent.
Gripper, George, J.P., Tottenham, Middlesex.
Harris, Walter H., 12, Kensington-gore, S.W.
Hay, John, 11, St. Mary-axe, E.C.
Hill, Frederick Barker, 30, Glengall-road, Peckham, S.W.
Hoblyn, Richard Armstrong, 79, Priory-road, West Hampstead, N.W.
Hogg, Quintin, 5, Cavendish-square, W.
Holt, G. Crompton, Albion-house, Congleton, Cheshire.
Hunter, William, Cathay-house, Eltham, Kent.
Husband, John, Moreton-lodge, Mount Pleasant-lane, Upper Clapton, N.E.
Hutt, Alfred Granger, 8, Oxford-road, Kilburn, N.W.

I'Anson, E. Blakeway, M.A., 7A, Laurence Pountney-hill, E.C.
Irvine, Hugh Alexander, Moray-place, Edinburgh.
James, Alfred, 157, West George-street, Glasgow.
Jones, J. Mortimer, 153, Highbury New-park, N.
Jones, W. Campbell, 32, Bedford-row, W.C.
Kenward, James, 280, Hagley-road, Birmingham.
L'Aker, Major John, Ascot-house, Boscombe, Bournemouth, Hants.
Lamington, Lord, 26, Wilton-crescent, S.W.
Lee, John T., 26, Great James-street, Bedford-row, W.C.
Leeson, Rev. Wilfrid Nevill, B.D., 84, Lancaster-gate, W., and New University Club, S.W.
Low, Alexander G., 38, Pembridge-villas, Bayswater, W.
McCormick, Rev. W. T., St. Matthew's-vicarage, Brighton.
McCormick, Robert, 72, Victoria-street, S.W.
Macnab, Henry Black, 1, Queen Victoria-street, E.C.
Martin, William, Lambeth Infirmary, Brook-street, S.E.
Meade, General Sir Richard John, K.C.S.I., 65, Queen's-gate, S.W.
Mewburn, George Francis, 10, Elm-park-gardens, S.W.
Miles, Colonel Samuel Barrett, The Residency, Oodeypore, Rajputana.
Millson, Alvan, Elmsleigh-house, Paignton, South Devon.
Moore, Alfred, 144, Mile-end-road, E., and Whips Cross, Walthamstow, Essex.
Moore, Commander William Osborne, R.N., 8, Western-parade, Southsea, Hants.
Muir, Thomas, 24, York-terrace, Regent's-park, N.W.
Norris, Walter Henry, Hertford.
Oliverson, Thomas, 2, Hyde-park-gate, South Kensington, S.W.
Phillipps, Richard, 78, Onslow-gardens, S.W.
Phillips, Rev. T. Lloyd, M.A., The Abbey, Beckenham, Kent.
Pilbrow, James, Belpi, Worthing, Sussex.
Piper, Charles Welborne, The Craig, Leyland-road, Lee, S.E.
Rawlinson, Alfred John, Newton-le-Willows, Lancashire.
Reade, Captain Charles Edward, R.N., Rodley-house, Willoughby-road, Hampstead, N.W.
Richardson, Edmund William, 50, Finsbury-square, E.C., and Friern Barnet, Middlesex.
Richmond, William Blake, M.A., A.R.A., Beavor-lodge, Hammersmith, W.
Rickett, William Richard, Sunnyfield, West-heath, Hampstead, N.W.
Riley, William Edward, H.M. Dockyard, Devonport.
Robinson, Prof. William, M.E., University-college, Nottingham.
Ryan, W. P., Ingram-court, Fenchurch-street, E.C., and Warrington-house, Richmond, Surrey.
Sadler, Colonel James Hayes, H.B.M. Consulate, Chicago, U.S.A.
Sandbach, Henry, 129, Mount-street, W.
Sanders, Henry C., Victoria Works, Victoria-gardens, Notting-hill-gate, W., and Elm-lodge, Southall, Middlesex.
Sawyer, Claude Gustav, Junior Constitutional Club, Regent-street, S.W.
Scott, Rev. Robert Selkirk, M.A., D.D., 16, Victoria-crescent, Dowanhill, Glasgow.
Scrutton, Alexander James, 75, Old Broad-street, E.C.
Sedgwick, Frederick Joseph, 72, St. Paul's-road, Burdett-road, E.
Seidler, Charles, 46, Eyot-gardens, Hammersmith, W.
Seton-Karr, Heywood Walter, Atherton-grange, Wimbledon, Surrey.
Smiles, Henry, Tregenna, Parkstone, Dorset.
Spielmann, Marion H., 16, Porchester-terrace, Kensington-gardens, W.
Stephens, Alfred, 3, St. Leonard's-terrace, Chelsea, S.W.
Stephens, Thomas Walls, Downe-house, Richmond, Surrey.
Stone, Edward, 5, Finsbury-circus, E.C.
Thomas, John Blount, J.P., 179, High-street, Southampton.
Thorp, William, B.Sc., 24, Crouch Hall-road, Crouch-end, N.
Verden, Henry, Cowley, Middlesex, and 14, Great Winchester-street, E.C.
Walker, William, Longfield-house, Trowbridge.
Walls, Edward John, 44, High-street, Eccleston-square, S.W.
Warner, William Harding, The Birches, Malvern-link, Worcestershire.
Williams, Henry, Norton-house, 79, Down's-park-road, Clapton, N.E.
Williams, Henry W., Park-house, Brentford, Middlesex.
Williams, Lieut.-Col. Robert, J.P., Bridehead, Dorchester.
Wimshurst, Henry William, 16, Thicket-road, Anerley, S.E.
Worland, Alderman Henry, 55, Barking-road, Canning-town, E.
Young, Prof. Sidney, 13, Aberdeen-terrace, White Ladies'-road, Bristol.

The CHAIRMAN delivered the following

ADDRESS.

In addressing the members of the Society of Arts a second time as Chairman of the Council, I rejoice to be able to congratulate the Society on a most successful session. The session of 1890-91 produced, as in my address of last year I expressed the hope that it would, papers well worthy of the Society and of the attention of

the members, thus maintaining the continuity of record to be found in the Transactions of the Society in relation to many important discoveries and inventions.

Before, however, referring to any of these subjects, I must refer to the losses by death sustained by the Society. I am thankful to say that these are comparatively few in number; they include the names of the Archbishop of York, Lord Granville, Sir John Hawkshaw, Mr. Loftus Perkins, Leonard C. Wyon, Mr. Willoughby Smith, Mr. William Hallowes, James Shirley Hibberd, and Mr. William A. Barrett. With regard to some of these it is fitting that I should add a few words in addition to the passing enumeration of their names. The pressing avocations of Dr. Thompson, the Archbishop of York, had prevented him during the latter years of his life from taking part in the progress of the Society, but I am glad to record, as an example to others, that he was the first examiner in logic and mental science appointed by the Council in the year 1860, and held that appointment until his translation to York.

Lord Granville was one of the oldest members of the Society, and was for many years closely connected with its work. He was elected a member in 1848, and was a Vice-President from 1849 to 1872; he again served on the Council from 1876 to 1880, and from 1882 to 1885. He on several occasions presided at the evening meetings of the Society, and took the chair at the centenary dinner held at the Crystal Palace in the year 1854. I need not remind members present that he was a Vice-President of the Royal Commission for the Great Exhibition of 1851, and Chairman of the Exhibition of 1862, and as late as the year 1868, when a very important conference was held under the auspices of the Society of Arts on the subject of technical education, Lord Granville showed his active interest in the subject and delivered a most important speech at one of the meetings of the conference.

In Sir John Hawkshaw the country has lost one of its most distinguished civil engineers, and the Society again one of its oldest members. He presided on many occasions, and took an active part in the discussions at the evening meetings.

In reference to the name and work of Loftus Perkins, there are many present in this room who were well acquainted with him and his work, and who still retain a lively recollection of his genial manners, affectionate disposition, and generous character. He was a descendant of Jacob Perkins, an American, who spent a large portion of his life in England, and himself took out no less than nineteen patents at a time when each patent cost £200, and who received a medal from the Society of Arts. His father, Mr. Angier Mark Perkins, also a member of the Society, developed a system of heating by high-pressure water, and invented the fixed and portable baking ovens now so well known throughout the whole length of this country. Mr. Loftus Perkins inherited, in no small degree, the inventive genius of his father and grandfather. He undoubtedly first had the courage to use, as it proved, with perfect safety, steam at a pressure which, but a few years before, would have been regarded as being beyond control, and in any description of the modern development of the steam-engine the work of Mr. Loftus Perkins must receive full notice. Nor were his talents confined to this subject only. The improved ammonia freezing apparatus, fully described in Mr. Graham Harris's course of Cantor lectures on "Heat Engines other than Steam," was perfected by him. He died at the comparatively early age of fifty-seven, his death being to a great extent brought about by the incessant labour entailed upon him in working up his inventions.

Mr. Leonard Wyon had been, from the year 1852, a member of the Society. He was the son of Mr. William Wyon, R.A., the chief engraver to the Mint. For many years he designed and produced all the medals of this Society, and his name, and that of his father, will long be connected with the art of engraving and modelling in metal.

The last of the names which time permits me to notice is that of William Alexander Barrett, who has for the last twelve years acted as the Society's examiner in music. I will not refer to the numerous works of Mr. Barrett, or to his association with many distinguished men in the development of musical education in this country. Those who remember his lectures on old English music, and the charming illustrations by which they were accompanied, will feel, I am sure, that these few words of regret for his loss find a fitting place in the address of the Chairman of the Council of the Society.

I now turn to a point of a pleasurable character, and that is to remind you that the Albert Medal for the year 1891 was presented, by the selection of our President, H.R.H. the Prince of Wales, on the recommendation of

the Council, to Sir Frederick Abel. On the present occasion, and in his presence, I cannot enlarge on the services which gained for Sir Frederick this well earned and honestly merited distinction; but all who have known Sir Frederick's work, and who know the self-denying life that he has passed in connection with his public services, will feel that amongst the many distinguished men whom this Society has been able to honour with the medal—which is regarded by all who receive it as one of the greatest honours that a scientific man can receive—there has been no more worthy recipient of it than Sir Frederick Abel.

It will be in the recollection of those who were good enough to attend, or to read my observations last year, that I at considerable length pointed out how there would be found in the papers from time to time read before the Society of Arts an almost complete history of various inventions, from their earliest conception to their ultimate development. Further consideration and experience has led me to ascertain that I by no means exhausted or did full justice to the work of this Society from that point of view; and were it possible to devote time to the elaboration of that subject, a most interesting and useful paper might be prepared, indicating particular dates at which the various steps of invention, which have been so rapid during the present century, took place. As, however, there are other subjects upon which it is of more importance that I should occupy your attention this evening, I propose to bestow only a very short period of the time allotted to me upon the subject, to which I have already referred. In connection, however, with the work of this Society I shall later on this evening have to present medals to those who have rendered distinguished service to the Society and its members by the merit of the papers which have been read during the last session, and I therefore desire for a few moments to supplement my address of last year by one or two further illustrations founded upon those papers.

There was read in the autumn of 1890 a most valuable paper by Messrs. Green, Cross, and Bevan, on "Photography in Aniline Colours," in respect of which the Society awarded one of their silver medals. It is interesting to note a fact, which escaped my attention last year, that in the year 1839 the silver medal of the Society was presented to Mr. J. T. Cooper for his method of preparing paper for photographic drawings. Closely connected to this is the subject of the paper of Professor J. G. Hummel, on "Fast and Fugitive Dyes." From its foundation, the Society has shown a keen interest in the improved production of dyes. Among the earliest premiums awarded were some in respect of the growth of madder in this country and the discovery of cobalt; and in the first extant volume of Transactions, published in the year 1783, it is announced that English madder, produced largely in consequence of the encouragement and awards offered by the Society of Arts, was found as good, at least, if not better, than any imported. And, again, in the year 1871, a most valuable series of Cantor lectures was delivered by Dr. Crace Calvert on "Dyes and Dye Stuffs other than Aniline."

Dealing with the artistic division of the Society's work, I have to notice two very remarkable papers, the merit of which in my judgment stands very high among the communications made to the Society. I refer to the papers of Mr. A. P. Laurie on the "Durability of Pictures Painted with Oils and Varnishes," and that of Mr. William Simpson on the subject of "Lithography." As early as 1786, a Miss Greenland brought before the Society a communication respecting the desirability of a substituted vehicle for colours in the place of oil. This paper will be found in the 5th vol. of the Transactions of the Society. She received a gold palette for her painting in wax, in accordance with the description as given in the Transactions; and, in 1797 and 1801, Timothy Sheldrake communicated to the Society papers "On the Nature and Preparation of Drying Oils for Painting Pictures;" in respect of which paper the silver palette was twice awarded to him by the Society. It is further interesting to notice that the distinguished artist, Mr. Holman Hunt, who presided on the occasion of the reading of Mr. Laurie's paper, read in the year 1880 a very valuable paper on the "Present System of obtaining Materials in use by Artist Painters," for which the Society's silver medal was awarded to him. I have not by any means exhausted the list in connection with this subject, but I have indicated again the continuity of interest evinced by the Society in this branch of art.

With reference to Mr. William Simpson's paper on "Lithography," in the year 1819 the gold medal of the Society of Arts was presented to Senefelder for his discovery of lithography; and it is recorded that he was so much gratified at the award that one of his lithographic

presses was presented to the Society. Medals were subsequently awarded to Hulmandel and Joseph Netherclift, and in 1847 a collection of specimens illustrative of the progress of lithographic art in England was exhibited in the rooms of the Society. If Mr. William Simpson be right in the argument of his paper, that lithography may be termed a finished chapter of illustrative art, it is not an exaggeration to say that every important step in its progress has been fostered and encouraged by the action of the Society of Arts. I shall have occasion to refer again, later in the evening, to this subject in connection with the pleasing duty which is imposed upon me of presenting the medals, and I pass from it now, commending it again earnestly to those who have the power and inclination to collect for the information of their brother members a record of progress and invention in any particular subject-matter.

I have every reason to hope that the coming sessions of the Society of Arts will be worthy of those that have gone before, and that the papers likely to be communicated and read to the various meetings will be at least of as much public interest, and contain as valuable information, as any preceding series. And I would commend to the members of the Society the extreme importance of attending at the meetings, in order that an effective discussion and criticism may follow the reading of papers in which matters of public interest, or the development of inventions, are discussed.

There is one other branch of the Society's work to which time will only permit me to give very passing notice, and that is the subject of Examinations. I need not remind my hearers that the interest which has been from time to time evinced in these examinations, or of the interest with which they have been supported by the public; but the figures for the last few years are exceedingly encouraging. Since the year 1885, that is to say, in the seven years from 1885 to 1891 inclusive, the number of papers worked in the examinations has doubled, *i.e.*, there were 1,313 in 1885, and 2,667 in 1891. I wish also to call attention to the improved standard of those who competed at these examinations; for, whereas in the year 1890, out of 2,474, 205 first-class certificates—in itself a very high average—were awarded by the examiners, in the year 1891 no less than 295, that is to say, nearly 15 per cent. of those who sent in papers obtained first-class certificates. I am quite certain, from the communications I have from time to time received with reference to these examinations, that they form a most useful part of the work of this Society, and one which strongly merits encouragement.

I now approach a subject of great interest to the Society, and which in one sense forms a novel feature in our proceedings to-day. I have to announce that Her Most Gracious Majesty has been pleased to appoint the President, Vice-Presidents, and Council of the Society of Arts, a Royal Commission for the International Exposition which is to be held at Chicago in the year 1893. I need scarcely say that the Council regard this, and I think the members of the Society will agree, as a very high compliment to the Society and a most gracious tribute to its work; and I shall, before I close my observations, appeal to all present, and to the members of the Society in all parts of the world, to render their assistance to the utmost of their power in justifying the selection so graciously made. It is not, however, unfitting that on such an occasion, and in view of such a fact, I should make a few observations upon the subject of exhibitions of the kind, and should also recall to the members of the Society of Arts the part that the Society has played in previous exhibitions. It is not saying too much to assert that the founders of the Society of Arts, or those who controlled its operations during the earliest periods of its existence, were the inventors of industrial exhibitions. Many suggestions have been made as to the first origin of exhibitions of this class, but I doubt if it is possible to discover their absolute origin. Sir Theodore Martin, in his "Life of the Prince Consort," traces them back to the mediæval fairs, and especially the fairs at Frankfort. The idea is ingenious, but I think it will be found that fairs were general throughout Europe at a much earlier period than the 16th century, and that they had little in common with the class of exhibitions to which I am about to refer. The French have claimed that the idea of industrial exhibitions originated with them, and, undoubtedly, in the year 1798, the then Minister of the Interior conceived and published the idea of annual public exhibitions of the products of French industries, and in September of that year such an exhibition was actually held in Paris. But, according to the report of the Paris Exhibition of 1889, which has recently been published, this had been preceded by an industrial exhibition held at

Prague in the year 1791. The French industrial exhibitions were carried out for some years, and it is certain that their success had some part in suggesting the idea of the great International Exhibition of 1851. But it must be remembered that the French exhibitions were distinctly national, and therein lay the great difference between the Exhibition of 1851 and subsequent exhibitions, and those which had preceded them. Strangely enough, a proposal in the year 1849 that the French Exhibition of that year should be international was rejected, and it affords marked testimony to the foresight of our then President, the late Prince Consort, that in the same year when asked by Mr. Cole as to whether he thought the British Exhibition shonld be national or international, the Prince replied at once "International, certainly." The minute, corrected in his Royal Highness's own handwriting, is in the possession of the Society. But simultaneously with the development of exhibitions in France, the first idea had been taking root and suddenly grew in this country. I believe the first exhibition of pictures was that held in the Louvre in the year 1699. The first exhibition in England was in the rooms of this Society in the year 1761. It was under the management of the Society, and the first of a series held under its direction, out of which series grew the annual exhibition of the Royal Academy. Again the distinction of the initiation of the first exhibition of an industrial character may certainly be claimed by this Society, for one was held in its rooms in the year 1761, when the machines which had gained prizes from the Society were exhibited, and from that may be traced the regular series of the exhibitions of inventions of select specimens of British manufactures, which, as developed in the year, 1846 were the immediate precursors of the great Exhibition of 1851.

In my opinion the 1851 Exhibition was the result of two distinct influences, the one emanating from France and the other which, under the auspices of this Society, had been developed in this country. I do not wish to-night to repeat the history which should be well known to every member of this Society. I mean the part played by its President, Vice-Presidents, Council, and members in the original proposal, and in the subsequent successful carrying out of that great first international exhibition. I have lately perused again the minutes of the years 1845 and 1849, which establish beyond all question that the idea of that great exhibition originated with members of this Society, was discussed in a practical manner on many subsequent occasions, and that the ultimate plan was the development of the resolution and action taken by the Society and its members. How thoroughly the idea was taken up by the President, the late Prince Consort, and how much his decision that the exhibition should be international, in the interest that he throughout evinced in the whole proceedings led to its success, has been well told elsewhere.

When, in the year 1862, the time seemed ripe for another exhibition, it was the Society of Arts which again took up the proposal, and by the establishment of a large guarantee fund, rendered its realisation possible. And with the series of exhibitions suggested by Sir Henry Cole in place of the third great international exhibition, which series commenced in 1871 and lasted until 1874, the Society was closely connected. It published the reports, its *Journal* was the official organ, and on many occasions the Exhibition Committees were appointed by, and did their work through, the agency of the Society. With the more recent exhibitions held at South Kensington, it has had an equally close connection. The committee meetings of the Executive Councils of the Health and Inventions Exhibitions were held at these rooms, and, with the permission of the Council, the Secretary of the Society was allowed to undertake important duties in connection with the executive department of both exhibitions. With regard to the Colonial and Indian Exhibitions, the Society undertook the duty of preparing the published reports, and its members were actively engaged in the work of the various sections. Nor is it in exhibitions in England alone that the Society has taken its share. Its assistance rendered to the Commissioners of the Vienna Exhibition in the year 1873 is acknowledged in the report; and it inaugurated a movement for sending artisan reporters to the Paris Exhibitions, both of 1867 and again in 1878, on each occasion publishing a most useful and valuable series of reports as to the result of these visits.

I may be pardoned if for one moment I venture to suggest that my colleagues on the Council are entitled to the confidence of the Society, and are fully qualified to perform those important duties which are necessary to be performed in order to secure efficient representation of British interests at the coming exhibition. If any one should have a doubt

on this matter I would only refer him to the list of names. There is no higher authority on this subject than Sir Philip Cunliffe-Owen. Sir Edward Birkbeck and Sir Frederick Bramwell acted as the most efficient chairmen, the one of the Fisheries Exhibition and the other of the Exhibition of Inventions and Music, while the Duke of Abercorn acted as vice-chairman of both the Health and the Inventions Exhibitions. In fact, I think it may fairly be said that there is scarcely one of the members of the Council of the Society of Arts who has not been personally connected with the active work of exhibitions.

And now I would for a few moments occupy your time by a reference to the coming exhibition in Chicago, the duties of the Society in relation to it, and the advantages which the Council believe are likely to result to the British people from and through an efficient representation there. After the extraordinary success of the French Exhibition of 1889, it was thought by many that no other international exhibition could equal, far less eclipse, that magnificent display. Now there is, in fact, no finality in these matters. Speaking of the French Exhibition of 1867, the late Sir Henry Cole, in his report, expressed the distinct opinion that it would be impossible to surpass it; and that it would be never worth while any more to try and hold a single great exhibition; and yet no one will deny that the Exhibition of 1889, from the point of view of interest, far surpassed its predecessor.

America, however, knows no such word as finality; and the citizens of the United States would be unworthy of the traditions of their immediate forefathers had they allowed the challenge to have remained unmet, that they could not equal, and, probably surpass, the efforts of other nations. Accordingly, the occasion of the 400th anniversary of the discovery of America by Columbus was taken as the occasion for the holding of a great Exhibition in America.

I am here almost tempted, parenthetically, to make an observation. You will of course note that I am leading up to an appeal to the members of the Society of Arts to interest themselves, for reasons which I will in a few words venture to put before you, in the great Exhibition to be held in Chicago in 1893. Do not for one moment suppose that I mean to suggest that we here in the old country, in Great Britain, have attained finality in this matter. I look forward with hope to an Exhibition, not many years hence, which may take place again on some spot in the vicinity of this great metropolis, in which all previous exhibitions elsewhere in the world may also be rivalled or surpassed. That is a subject which will be dealt with I trust by some future Chairman of Council, and I will not deprive him of the pleasure of having an unbroken and undisturbed field.

Into the discussion as to the place to be chosen I will not here enter, as it belongs to the region of past history, the discussion of which is not of any particular advantage to members of the Society. Suffice it is to say that between the rival claims of New York, St. Louis, and Chicago, I may be allowed to express the opinion that the American people have exercised a very wise discretion in recognising the enormous advantages of the position of Chicago; and a firm belief that every feeling of rival interest has long since disappeared, and that the people of America have determined that the World's Columbian Exhibition of 1893 shall be, in every sense of the word, the greatest international exhibition the world has ever seen.

During the vacation the Council have sent their Secretary, Sir Henry Trueman Wood, who has, as you all know, a very large experience of exhibitions, in company with Mr. Dredge, a member of the Council, in a visit to Chicago, in order to obtain the best information upon all matters of interest to exhibitors or others likely to visit the exhibition in 1893, and I would refer the members of the Society to the very excellent paper read by Mr. Dredge, in the course of last session, and the equally, or I think I may say the still more valuable report of Mr. Dredge and Sir Henry Wood, which appeared in the *Journal* of the Society on the 23rd of October last. I have also the gratification of being able to announce that the subject is to receive still further notice in a paper to be read by Mr. Dredge on Wednesday, December 9th next. For myself, I would only say that situate as Chicago is, as the centre of a numerous population, the focus and terminus of nearly every great railway from every quarter of the States, the principal port on the great lake and canal system of America in connection with the Mississippi and the Gulf of Mexico, I do not see how it is possible that any better site for a successful exhibition could have been chosen.

With regard to the Exhibition itself, as I have already said, I do not wish to repeat what

can be gathered with greater advantage from the paper and report to which I have alluded; but it may be of interest to my hearers to know that Jackson-park, in which the Exhibition is to be held, is almost as large as Hyde-park, and that the whole of its vast area will be devoted to buildings appropriated to the various purposes of the Exhibition. Much more I could add with reference to the progress of the buildings, the accommodation to be afforded, and other particulars respecting the Exhibition, but upon those subjects I recommend the attention of all to the publications of the Commission and to the papers, in which full particulars can be found, but on behalf of the Commission I would earnestly appeal to the members of the Society to consider the extreme importance to British subjects and British industry, that the manufactures and art productions of the United Kingdom and the British Empire should be worthily represented.

Chicago will be visited not only by Americans and citizens and residents in the United States, but by the merchants and industrial classes of all nations. There is no doubt whatever that enormous numbers of visitors will come from South America. Efforts have been made by American traders, and possibly by the American Government—efforts which, from their point of view, we must regard as legitimate, to divert to the United States some portion of the great trade which has existed for so many years between South America and England. Americans, not unnaturally, consider that the Exhibition will afford an opportunity for furthering this policy; but, if so, of what immense importance it is that to these South American visitors should be shown the fact, by ocular demonstration, that the manufactures and products of British commercial industry maintain their position of equality, and, in many cases, of superiority. Again, the opening up of routes to the West will undoubtedly lead to very large numbers of Australians, Chinamen, and Japanese visiting the Exhibition, and it is obvious that a defective exhibition of British industry must have the effect of losing for British trade custom and prestige in those countries. In the race for success one cannot blame those who fight for themselves, and it must be remembered that a fine display of British goods would attract custom not only to the particular exhibiting firms, but to British industries generally; and it is for this reason that I would commend to the consideration of exhibitors the importance of forming collective exhibits representing the various branches of the industries of these countries.

I may be asked what class of exhibits will specially appeal to visitors to this Exhibition. I would reply, any of those productions which conduce to the happiness, comfort, health, and amusement of civilised races. At Chicago and in many great cities of the West, there is rapidly springing into existence a wealthy class who are only beginning to acquire the ideas of luxury and refinement. Large and magnificent houses are the natural outcome of the successful career of the traders in these young cities. From the point of view of artistic decoration, they must turn, or be led to the cultivated and developed tastes of the older European nations; and the same observation applies, in a marked degree, to the exhibition of works of art. The British school of painting is far less known in America than it deserves to be—much less than the French school—and there are hundreds, nay, thousands, who are willing and likely to expend large amounts in pictures and works of art, both for the decoration of their own houses, and also for the ornamentation of public buildings; and, with the little scope and market that now exists in the United Kingdom for the productions of English art—though this may be considered as putting the matter on rather a low platform—I earnestly commend to those interested in the arts of this country—both painting, sculpture, and drawing—the importance of the British nation being well represented in the Art Section. That the British exhibitors at Chicago will be welcomed in a way in which they would be received in no other country in the world is certain. Despite what may be said to the contrary, there is no country where Englishmen are so cordially welcomed or so well treated as in America, and no country in which English opinion, or the action of England, is so carefully watched or so highly regarded. I am in a position to state that the other European nations and other nations of the world will contribute to the Chicago Exhibition, at least to as large an extent as they have to any other undertaking of the kind. Practically, all the European countries have already announced their intention of being represented. Germany will probably fill a larger space than her exhibitors have ever before filled at an international exhibition. French art and French industry will be largely represented, and although it is yet early to speak about the exhibitors from Great Britain,

I am already in a position to state that, from the applications received, the Council entertain no doubt that the industries of the United Kingdom should take as prominent a place at Chicago as they have filled on all previous occasions when great international exhibitions have been taking place. I hope and have every reason to believe that our great Indian Empire will be fitly represented, and though my information does not enable me to speak positively as to the action of the British colonies, the Commissioners hope soon to be able to announce that the Court of the mother country will be in close proximity to the Courts containing the productions of Canada, Australasia, and British Africa, and that the British colonies will be represented (at least, I trust so) almost to as large an extent as at that magnificent Colonial Exhibition at South Kensington in 1886.

Before I conclude, I desire to read to this meeting a passage from a speech somewhat long, but yet which, when I came across it the other day in preparing for this address, occurred to me to be so good and so useful that I could not to any advantage curtail or cut out a single word of it. I will read this passage to you; I will then tell you whose words they are, and I will endeavour, in my concluding observations, to point one or two remarks founded upon the argument used in this passage:—

"Gentlemen, I conceive it to be the duty of every educated person closely to watch and study the time in which he lives, and, as far as in him lies, to add his humble mite of individual exertion to further the accomplishment of what he believes Providence to have ordained. Nobody, however, who has paid any attention to the particular features of our present era, will doubt for a moment that we are living at a period of most wonderful transition, which tends rapidly to the accomplishment of that great end to which, indeed, all history points—the realisation of the unity of mankind. Not a unity which breaks down the limits, and levels the peculiar characteristics of the different nations of the earth, but rather a unity the result and product of those very national varieties and antagonistic qualities. The distances which separate the different nations and parts of the globe are gradually vanishing before the achievements of modern invention, and we can traverse them with incredible ease, the languages of all nations are known, and their acquirement placed within the reach of everybody; thought is communicated with the rapidity and even by the power of lightning. On the other hand, the great principle of division of labour, which may be called the moving power of civilisation, is being extended to all branches of science, industry, and art. Whilst formerly the greatest mental energies strove at universal knowledge, and that knowledge was confined to the few, now they are directed to specialities, and in these, again, even to the minutest points; but the knowledge acquired becomes at once the property of the community at large. Whilst formerly discovery was wrapt in secrecy, the publicity of the present day causes that no sooner is a discovery or invention made than it is already improved upon and surpassed by competing efforts; the products of all quarters of the globe are placed at our disposal, and we have only to choose which is to be the best and cheapest for our purposes, and the powers of production are intrusted to the stimulus of competition and capital. So man is approaching a more complete fulfilment of that great and sacred mission which he has to perform in this world. His reason being created after the image of God, he has to use it to discover the laws by which the Almighty governs His creatures, and by making these laws his standard of action to conquer Nature to his use—himself a divine instrument. Science discovers these laws of power, motion, and transformation; industry applies them to the raw matter which the earth yields us in abundance, but which becomes valuable only by knowledge; art teaches us the immutable laws of beauty and symmetry, and gives to our productions form in accordance with them. Gentlemen, the Exhibition of 1851 is to give us a true test and a living picture of the point of development at which the whole of mankind has arrived in this task, and a new starting point from which all nations will be able to direct their own further exertions. I confidently hope the first impression which the view of this vast collection will produce upon the spectator will be that of deep thankfulness to the Almighty for the blessings which he has bestowed upon us already here below, and the second, the conviction that they can only be realised in proportion to the help which we are prepared to render to each other, therefore, only by peace, love, and ready assistance, not only between individuals, but between the nations of the earth."

That is a long quotation, but I think everyone who has followed it will agree with me that it is a quotation worth recalling to the mind of this Society. The words are taken from an address of the President of this Society in the year 1850, the late Prince Consort; and I would desire with all seriousness and all earnestness, as for the moment, and for the moment only, the mouthpiece of the Council of this Society, to point out to you the remarkable prophecies which are contained in these utterances, and with what truth they have embodied precepts which we ought to follow to-day. The late Prince Consort spoke of the destruction of distance. Why! what may

have seemed wonderful in the year 1850, has as you all know, been surpassed in the year 1891. Since then, the dreams and romances of the novelist have been proved to be not only realities but to be surpassed by actual facts. And do I refer to the rapidity of communication? Why you know perfectly well that not only in matters which affect the interests of nations, but in any subject which is exciting the attention of any large number of inhabitants of any civilised nation, no sooner has a publication been made than in a few seconds, sometimes in advance of the time at which the utterance has been made, it is wafted to the ends of the world by the electric wire, and becomes the topic from which other demonstrators take their starting point at the other end of the world. What does this point to? I remind you again of the remarkable sentence that the blessings bestowed upon us by this development, the result of science, the result of the diffusion of useful knowledge, can only be developed to the fullest degree, to the happiness of the greatest number, by each one being prepared to render to each other ready assistance, not only as between individuals but as between the nations of the earth. Many may think—nay, I know many have thought—though I hope and believe that that has almost entirely passed away—that, owing to commercial questions which have arisen in America, it might not be worth while for British traders to be anxious and keen that an exhibit worthy of the British nation should be there displayed. I believe most heartily that there was never any more mistaken notion. I believe there is nothing that the Americans would be more likely to appreciate than the sense that, whatever temporary disadvantages British commerce and British trade may have laboured under, still there was sufficient good fellowship, sufficient loyalty to the interests of mankind as apart from the interests of a particular nation, to lead the great manufacturers of this great country to determine that they would be worthily represented. But surely there is a higher, a loftier principle embodied in these noble observations, which, if they were true in 1850, are as true in the year 1891. Surely we must see that one result of this great Exhibition, if it does not lead at once to that universal peace which was the dream and aspiration of some of the founders of the Exhibition of 1851, yet must tend to draw closer together the bonds of friendship between the civilised nations of the earth. It must tend to make thinking men feel that they are members of one family, and that though they may be born under a different clime, and under circumstances dependent on their being resident in different parts of the earth, yet still in the cause of common humanity, in the cause of civilisation, it should be the aim of every thinking man to promote that universal feeling of good will which must ultimately bind and draw closer together all the nations of the earth. I know that individual members of the Society cannot do much; but, on the other hand, there are many members who can do a great deal. The Council has undertaken a work which they conceive to be a great work: they have undertaken a task in which they ask for the co-operation and support and assistance of all the members of the Society, extending, as we know they do extend, to every quarter of the United Kingdom, and I might say to every part of the civilised world; and I trust and believe that the appeal made in these few words from me will not be in vain. I do ask that you will appreciate and understand the work the Council have undertaken, and that you will, through your advocacy, through your agency, and through your instrumentality, do your best to supplement and assist in that work, and make the British Section of the great Exhibition at Chicago worthy of the great nation of which you are proud to be members.

Sir Richard Webster then proceeded to present the medals awarded by the Council for papers read during the last session, in accordance with the following list:—

At the Ordinary Meetings:—

To J. F. GREEN, for his paper on "Steam Lifeboats."

To A. G. GREEN, C. F. CROSS, and E. J. BEVAN, for their paper on "Photography in Aniline Colours."

To CARMICHAEL THOMAS, for his paper on "Illustrated Journalism."

To Colonel Sir CHARLES WILSON, K.C.B., K.C.M.G., F.R.S., for his paper on "Methods and Processes of the Ordnance Survey."

To A. P. LAURIE, for his paper on "The Durability of Pictures painted with Oils and Varnishes."

To Prof. WILLIAM ROBINSON, for his paper on "The Use of Petroleum in Prime Motors."

To Prof. J. J. HUMMEL, for his paper on "Fast and Fugitive Dyes."

In the Indian Section:—

To B. H. BADEN-POWELL, C.I.E., for his paper on "The Indian Village Communities, with Special Reference to Modern Investigation."

To THOMAS WARDLE, for his paper on "The Use of Tussur in European Textile Manufactures."

To CHARLES L. TUPPER, B.A., for his paper on "The Study of Indian History."

In the Foreign and Colonial Section:—

To Sir EDWARD N. C. BRADDON, K.C.M.G., for his paper on "Recent Development of Tasmanian Industries."

To Sir THOMAS WADE, G.C.M.G., K.C.B., for his paper on "China."

In the Applied Art Section:—

To WILLIAM SIMPSON, for his paper on "Lithography: a Finished Chapter of Illustrative Art."

To G. T. ROBINSON, F.S.A., for his paper on "Decorative Plaster Work: Modelled Stucco Work."

With regard to the first medal, Sir Richard remarked on the painful lesson we had recently learned as to the necessity for more efficient lifeboats, and on the satisfaction which all must feel at seeing a getleman so eminent in connection with the mercantile marine as Mr. Green devoting his abilities to this matter.

The paper on "Photography in Aniline Colours" he had already referred to.

Mr. Carmichael Thomas had given a most interesting paper on "Illustrated Journalism," and those who, like himself, had had the pleasure of inspecting the machinery and arrangements at the *Daily Graphic* office must have been very gratified at seeing the wonderful developments which had been effected in this direction.

Sir Charles Wilson, who was unfortunately unable to be present, was specially employed in Egypt in 1882-83; he was at the head of the Intelligence Department of the Nile Expedition in 1884; was Director of the Survey of Ireland in 1883-84, and since 1886 had been Director-General of Ordnance Survey.

Mr. A. P. Laurie, to whose paper he had already referred, was a Fellow of King's College, Cambridge, and Lecturer at Toynbee Hall; and he was glad to be able to announce that the Council had selected him to give a course of Cantor lectures in the coming session.

The Society had often been charmed by the papers and lectures of Professor Silvanus Thompson; and Professor William Robinson, who took the next medal, was formerly an assistant of his at the Finsbury Technical College, and no doubt largely benefited by his connection with it. He was now Professor of Engineering at the University College, Nottingham.

Professor Hummell's paper he had already noticed.

The name of Mr. Baden-Powell was well known as connected with the very distinguished gentleman who at present represented British interests in connection with the seal industry in Behring Straits, and if he mistook not, the recipient of the medal was also eminent in connection with the subject on which he had read the paper for which the medal was awarded.

Mr. Thomas Wardle's name was very familiar in the Society, and he was distinguished by his efforts for the improvement and advancement of the silk industry generally, and especially with a material which was for a long time considered of very low value if not almost a waste product—Tussur silk. He was chairman of the silk culture department in the Colonial and Indian Exhibition and President of the Silk Association for Great Britain and Ireland. Many people thought silk was produced by only one insect, but Mr. Wardle had given a list of some eighteen or nineteen different insects from which it might be obtained.

Mr. Charles Tupper had been for some time Chief Secretary to the Government of the Punjab, and had made a special study of Indian records in connection with the subjects dwelt upon in his paper.

Passing from India to the Colonies, he again came to a gentleman bearing a very well known name, Sir Edward N. C. Braddon, who, he believed, was a near relative of the lady whose imaginative powers had delighted so many readers.

Sir Thomas Wade, in his paper on "China," brought to bear no ordinary experience. Originally in the army, his career in China commenced in 1843; and, from 1871 to 1883, he was Envoy Extraordinary and Minister Plenipotentiary, as well as Chief Superintendent of British Trade in China. It was a great honour to the Society that a paper should have been contributed to its proceedings by so distinguished a man.

Mr. William Simpson, who came next, had claims of a different kind. Originally a practical lithographer, he was the author of one of the finest specimens of book illustrations in lithography, and was also special correspondent of the *Illustrated London News* on many important occasions since the Crimean war.

Mr. G. T. Robinson, who, unfortunately, was not present that evening, was one of the earliest to introduce from Italy the use of various kinds of artistic plaster work, which flourished to such a high degree in the

seventeenth and eighteenth centuries, but which, in the early part of this century, had almost disappeared in connection with house decoration.

Sir FREDERICK BRAMWELL, F.R.S., said it had been his privilege to hear many addresses by chairmen of that Council, and of each he had felt inclined to say that it was as good an address as ever he had listened to. Certainly he was not going now to depart from that time-honoured and, as a rule, truthful statement. They had had from Sir Richard Webster a most useful and most earnest address, which no one could have heard without feeling that he had stated forcibly and truly the useful work of the Society, now about a century and a third old; that he had urged very appropriately the importance of that work being continued, and that he had very properly referred to the honour conferred upon the Society by the Council being appointed the Royal Commissioners for the Chicago Exhibition. In reference to that matter, he would ask all present to remember the earnest words which the chairman had used—well qualified to accompany the noble extract which he had read from the Prince Consort's speech in 1850. Sir Richard Webster was not merely addressing those present, but through the Press the whole of England and a large number of English-speaking people throughout the world. He had called attention to the improvements which had been made in the rapid transmission of intelligence, and, thanks to that improvement, it was not improbable—nay, it was almost certain—that to-morrow the gist of those words would be read in Chicago itself, and that they would there see that we in this country were determined to do our very best—under the guidance of the Commission, presided over by the Prince of Wales, but the real working head of which was Sir Richard Webster—to make the Exhibition a success, so far as the United Kingdom was concerned. He need say no more in proposing that the best thanks of the Society be given to Sir Richard Webster, Chairman of the Council, for his address.

Lord ALFRED CHURCHILL cordially seconded the motion. He remarked that many of the members were probably unaware of the great services which Sir Richard had rendered to the Society since he had been connected with it, and especially since he had occupied the chair. It was mainly due to his exertions and influence that the Council had been honoured by being appointed the Royal Commission for the Exhibition, the only instance of the kind, he believed, which had ever occurred. He hoped that he would continue to hold office until the close of the Exhibition.

The motion having been carried unanimously,

Sir RICHARD WEBSTER, in reply, said he was exceedingly grateful for the kind words spoken by his old friends, Sir Frederick Bramwell and Lord Alfred Churchill, and still more for the kind reception given to the proposal. It was no light task to undertake the duties of Chairman of the Council of that Society. As he had said last year—and he felt it even more to-day—looking back on the great men who had preceded him, many of whom were fitted, from their personal knowledge and research, to guide and instruct the Society on many branches of modern science—it seemed almost presumptuous for a lawyer to fill such a place. But he had brought to bear upon the work connected with the Society all the energy and all the powers of application with which God had been pleased to endow him, and at any rate he had given them the best he could. If after his year of office was over the Society thought he had not unworthily filled the position, he and his family would always be proud of his connection with it.

Miscellaneous.

TURIN COMMERCIAL MUSEUM.

The following communication of the Director of the Museo Merciologico at Turin, asking for the gift or loan of specimens of the products of the United Kingdom, for exhibition in the Museum, has been received from the Science and Art Department:—

Museo Merciologico di Torino,
Exposizione Permanente di
Materie prime del Commercio e dell' Industria,
Corso Palestro, 1bis.

Torino, 21 Août, 1891.

La Ville de Turin a ouvert depuis plusieurs années un Musée Merciologique ou Commercial, fondé par moi-même en 1860. Dans cette exposition permanente et gratuite peuvent être dignement représentés tous les produits naturels et manufacturés de chaque pays du monde.

Parmi eux l'on désirerait y voir figurer les matières premières des industries et les produits du sol de ce Royaume Uni.

Les noms des Exposants-Donateurs seront inscrits dans un album spécial et sur des tableaux à l'entrée du Musée.

Avec l'espoir d'une réponse favorable, je vous remercie à l'avance pour tout ce que vous voudrez bien faire au profit de cette institution d'utilité internationale, et vous prie d'agréer, Monsieur le Ministre, l'expression de mes sentiments de haute considération.

Votre trés-dévoué serviteur,
Le Directeur du Musée,
(Signed) PROFESSEUR G. GARNAUDON,
Conseiller Com. de la Ville de Turin.

A Son Excellence
Monsieur le Ministre
de l'Agriculture et du Commerce,
pour la Grand Bretagne et l'Irlande.
à Londres (Angleterre).

PRODUCTION OF IRON ORE IN THE UNITED STATES.

It appears from a recent bulletin issued by the United States Census Office, that during the year ending December 31, 1889, the production of iron ore in that country amounted to 14,518,041 long tons, which was contributed by twenty-six States and two territories, and this output represented a value at the mines of $33,000,000, an average of $2·30 a ton. Michigan was by far the largest producer of iron ore in the census year 1889, a total of 5,836,169 long tons having been mined, the value of which was $15,800,521 at the mines. The amount from Michigan therefore represents 40 per cent. of the total, while the aggregate value is 47 per cent. of that of the entire country. The credit of holding second rank lies between the States of Alabama and Pennsylvania, the former having a slightly greater output than the latter. The production of Alabama in 1889 was 1,570,319 long tons, valued at $1,511,611. These figures represent 10·8 and 4·5 per cent. respectively of the total output and value. Pennsylvania closely follows Alabama, its output being 1,560,234 long tons, valued at $3,063,534, 10·7 and 9·2 per cent. respectively of the total output and value. The other State which produced over 1,000,000 tons in the census year was New York, which is credited with 1,247,537 long tons, valued at $3,100,216. These four States, therefore, produced a total of 10,234,259 long tons, or 70·5 per cent. of the entire output of the iron ore mines of the United States, while the value of the ore amounts to $23,475,882, or 70·4 per cent. of the total valuation.

TECHNICAL EDUCATION AT ST. ETIENNE.

For the past twenty years the French Government has devoted a great deal of attention to the education of the people. National schools, says the United States Consul at St. Etienne, have been opened in almost every village, and the instruction given is of a very useful order. Besides the primary schools, there are superior schools where diplomas for "great merit" may be obtained. These latter, however, are only attained by pupils belonging for the most part to the middle classes, who intend to become teachers or governesses in public or private institutions, or by those who have no other purpose in view than of being considered fairly well educated. As the working classes, on the other hand, cannot afford for their children the expenditure of time and money which a course of these higher schools involves, they are obliged to withdraw them when they have received the certificate of elementary education which is generally given to children between the ages of twelve and thirteen. It is for this poorer class that towns of importance throughout France have established well equipped schools where various trades are taught gratuitously, both practically and theoretically. St. Etienne being one of these important cities, with 130,000 inhabitants, possesses a model, well organised, and successful technical school. The technical institution of St. Etienne was built in 1885 at a cost of £23,120. The school has three hundred students, and the trades taught are weaving, dyeing, sculpture, iron founding, cabinet making, &c. The apprenticeship is four years in duration, and the institution is free. At the end of four years, a certificate of aptitude is given, which enables the pupil to obtain a situation in the line of industrial labour which he had chosen. The work of the school begins each day at seven in the morning, and ends at seven in the evening. The school is composed of two buildings. The first is reserved for general education, and the second contains the different workshops, occupying 1,400 square metres of surface. The fitting up of these workshops is very complete, and comprises vices, lathes, boring, planing, and other machines, forges, anvils, steam hammers, carpenters' benches, circular saws, weaving machines of every variety, and all the accessories of the dyeing industry, as well as important collections of chemical and physical apparatus. The whole building is lighted by electricity. The lectures are of two kinds. The first are common to all students of the same year, and embrace general subjects, while the second are exclusively technical, and are special to each section. In the first year, the students pass through all the workshops to be initiated into the proper handling of the different tools, whether of iron or wood. After this period, the boys are classed according to their tastes, desires, and aptitudes. They work at manual labour three hours daily during the second year, four hours in the third, and five in the fourth. and last year for the first six months, and seven hours during the last six months, in order to accustom them to the burden of a day's work. During this period, also, great attention is paid to the teaching of the theory of the different trades, that is to say, the fitters are taught to trace and cut out cog-wheels, and the carpenters to design and execute a certain number of apparatus, such as stairs of different variety, shutters, balconies, &c., on a reduced scale. The weavers, besides being taught thoroughly all the details of the loom and its working, receive special lessons in book-keeping, legislation, commercial geography, and are taught one of the modern languages. Very careful attention is paid to design. The apprentices at all the trades are obliged to follow the instruction given on this subject, which is rightly considered of the greatest importance in the school. Designs of various kinds are executed by the more advanced sections, and every year an exhibition of the work of the boys is held. Consul Loomis says that the results of this school have been most excellent, and he has been informed that, as a rule, its graduates become self-supporting members of society in a very short time.

PRODUCTION OF OLIVE OIL IN THE MARITIME ALPS.

The olive covers about 70,000 acres in the Department of the Alpes Maritimes, and it yields a revenue of over £400,000. The United States Consul at Nice says that there seem to be but two species of olive trees in the south of France, the oleaster (wild olive), having a kind of thorn, very short leaves, and producing only a few small berries, which neither the *dacus* nor the boring caterpillar will attack; the sativa (cultivated olive) is another description, which produces a large fruit. Seedlings of the sativa sometimes deteriorate, so as not to be distinguished from the oleaster. There are several varieties of the above, the principal of which are the following:—The *blanquetier*, which has a light green foliage, bears a small fruit, and produces oil abundantly. The *blavier* is very hardy; its fruit is oblong, and comparatively large; the pulp is coarse, and the oil deeply coloured. The *arabanier*, or *araban*, is a tree hardier than either the *blavier* or the *blanquetier*, and the oil produced from the fruit is of ordinary quality. The *calletier*, which is also known by the characteristic name of *pendoline*, thrives best in dry soil, and, at its best, its fruit sells for a third more than others for mixing with poorer qualities. Other good varieties for oil are the *nirvana*, the *auriola*, the *nicoise*, the *blanche*, the *roberon*, the *negrette*, the *caillan*, &c. The olive tree flowers every year; and some growers advocate an attempt to gain a yearly crop, but the majority are content to try to get a good crop every two years. The trees bud in May, and flower in June. Olives, to be preserved green, are picked in September; those destined for oil, from November until the following May; but the best results, to crop and tree, seem to follow harvesting, near midwinter, when the olive is black, though oil made from olives gathered as late as Febrnary and March is preferred for its keeping properties. The farmers in the neighbourhood of Nice spread sheets under the trees, and knock the fruit down with poles, injuring both fruit and tree in so doing. The harvest is gathered largely by Italian women, who come into France for that purpose, and they are paid by the quantity gathered, boarding themselves. The olives being gathered, the farmer either takes them to the mill at once, or spreads them in the sun or granary to dry out some of the moisture. The mill in use at the present day to crush the olives differs little from those used for centuries. The olives are poured into an enormous stone bowl, from the centre of which rises a large wooden shaft crowned with a large wheel; in the rim of the wheel, pointing downwards and regularly spaced, are strong oak pegs for cogs. These pegs meet similar pegs or cogs in the power wheel which is turned slowly by an overshot water-wheel. Attached to an upright shaft, forming an acute angle with its lower end, is a large millstone, exactly the shape of a large grindstone, the edge bevelled to match the slightly concave bottom of the great bowl, and from the side of the upright shaft opposite to the great millstone, on the end of a short horizontal shaft, is a scraper which fits the inner side of the bowl. When the mill starts the olives in the bottom of the bowl are crushed by the stone, these forced up the inner sides of the bowl as the great stone revolves, are scraped off and drop back under the stone until the mass is reduced to an oily paste. This paste is packed into woven grass bags, which are then taken to the presses; these presses are simply rough heavy frames fitted with large screw presses worked by hand. The bags are then piled up on a wide oaken slab forming the bottom of the frame, the presses are screwed down upon them with a hand-bar, the oil drains into tubs placed to receive it, when boiling water is poured over the bags to help the flow and joins the oil in the tub. The oil rising to the surface of the water is skimmed off with large tin skimmers. A mill has lately been invented, says Consul Bradley, by the director of the agronomic station of Nice, which, as it crushes the pulp, extracts the stone and throws it out, thus allowing the oil of the pulp, the true virgin oil, to be obtained fiom the press without any admixture of that obtained from the stone or kernel. In preparing virgin oil, which, as it requires so much care and attention to prepare, is difficult to obtain, the following system is adopted. Olives are taken when only three-quarters ripe, and they are selected free from any blemish. They are taken, immediately after they are gathered, to the mill, where they are but slightly crushed, so that the pulp alone comes in contact with the millstone; the seed must not be touched, for though the kernel contains a certain quantity of oil, it is rather acid, and has not so fine a taste as the oil from the pulp. This pulp having been crushed without the addition of water, is gathered in a heap, the centre of which is made hollow in the shape of a funnel. The oil flows by itself from the inner sides into the centre of a reservoir, from which it is taken with a large ladle. The oil so prepared is greenish in colour, its perfume is exquisite, and it can be kept for many years. For oil of the first quality, called "cannon oil," the olives are placed in the mill without addition of water, if the fruit is freshly gathered. The oily paste is placed in bags, made of clean esparto, and put into the press. To obtain second quality oil, and to extract from the pulp all the oil which it contains, the contents of the bags are thrown into a vat full of cold or warm water; the whole is well stirred up, the broken fragments of the seeds fall to the bottom, while the pulp floats, and the latter is gathered and replaced under the press. After all the usual means of extracting the oil from the pulp have been employed, 10 per cent. of oil can still be obtained by using bisulphide of carbon. After the oil is extracted, the skins and refuse are employed in heating boilers, the muddy substance found at the bottom of the most inferior quality of oil is used as manure; and, last of all, the broken stones, or *grignons*, make a very excellent fuel, which has the

advantage of not giving off any carbonic acid gas, as charcoal does. Consul Bradley says that fraud is found in the oil mills as in other places. Should the olives be mouldy, which often happens when they have been gathered or kept in bad condition, the bad taste is hidden by adding leaves of wild olive trees to the pulp. Some olive growers even go so far as to throw seed oils over the pulp while it is being ground, so as to get a perfect blending with the new oil. To keep the oil in good condition requires great care and attention. The clear oil is separated from the turbid at once, for the longer the oil remains on the lees the more apt it is to contract a rancid or a bad odour. When the oil has been decanted several times, filtered through dry moss, carded cotton, sand, plaster, charcoal, &c., it is stored in a place which is sheltered both in summer from the heat, and in winter from the cold. The oil must be kept in vessels which close tightly, and are made of a substance on which oil has no action. These precautions are indispensable, for the effect of the air on oils is too well known not to be guarded against.

PRODUCTION AND CONSUMPTION OF VANILLA.

Paris, London, and New York are the markets of the world for Vanilla; after these, says Consul Knowles, of Bordeaux, that city occupies an important place. Great quantities of the bean are used in France. It is employed in making confectionery, ices, liqueurs, and cordials, and enters into the manufacture of perfumery. Vanilla is of Mexican origin, though found in almost every tropical country. It is a vigorous rind of the orchid species, about twenty to thirty feet in height, with heavy, oblong, sea-green foliage. It thrives in dense forests, where its branches entwine and interlace themselves with neighbouring trees. The stem is four-cornered, the flowers large, fragrant, and spikelike. It yields to cultivation. The greater part of the vanilla imported into France comes from her colonies—Guadeloupe, Madagascar (Sainte Marie), Mayotte, the island of Réunion and Tahiti. The production, in 1889, of vanilla in these colonies amounted respectively to 9,000, 19,000, 19,000 506,000, and 7,000 pounds weight. The vanilla tree begins to yield in its third year, and from thence to its thirtieth. The season commences in the month of April, and lasts until the middle of June. The beans are gathered in the green state, before maturity. There are two existing methods of curing manilla. In the first of these, the beans are laid in quantities on great cloths spread upon the ground, and exposed to the sun for a period of two months, or until they have attained a dark brown colour. They are then packed in bundles of fifty, and placed in tin boxes for exportation. The second method consists in attaching, by their inferior extremities, a number of the beans, and immersing the same in a vessel of boiling water, until they become white. They are then exposed for a few hours only to the sun, after which they are covered with a native fixed oil, usually that of the cashew nut. There are four qualities of vanilla, and these are determined by the length and size of the bean, it being found that the flavour and perfume are in direct ratio to their weight and measurement. In appearance the beans are slender and cylindrical, averaging about five or six inches in length, and half an inch in thickness. Within is a soft black pulp. The quality of the bean is further enhanced by the exudation of a certain needle-like crystal or effloresence which covers the surface of the fruit, and is called in French *vanille givrée*. The crystals are found to be almost pure benzoic acid. The imports of vanilla into France, which amounted, in weight, to 198,000 lbs. in 1880, exceeded 258,000 in 1889.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, Nov. 23...Royal Scottish Society of Arts, George-street, Edinburgh, 8 p.m. Mr. William Scott Morton, "Tyncastle Modelled Canvas and other Decorations."

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. J. R. Adams, "The Title to Land, its Registration and Transfer."

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Mr. St. George Littledale, "A Journey across the Pamir from North to South."

London Institution, Finsbury-circus, E.C., 5 p.m. Prof. Knight, "Spinoza: the Man and his System."

TUESDAY, Nov. 24...Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on the papers by Messrs. Bamber, Carey, and Smith, "Portland Cement and Portland-Cement Concrete."

Anthropological, 3, Hanover-square, W., 8½ p.m. 1. H. Mitford Barber, "Perforated Stones of South Africa." 2. Mrs. S. S. Allison, "Notes on the Indians of the Similk'ameen, British Columbia."

WEDNESDAY Nov. 25...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Prof. Silvanus Thompson, "The Measurement of Lenses."

Geological, Burlington-house, 8 p.m. 1. Prof. H. G. Seeley, "The Os Pubis of *Polacanthus Foxi*." 2. Prof. Edward Hull, "A Comparison of the Red Rocks of the South Devon Coast with those of the Midland and Western Counties." 3. Rev. A. Irving, "Supplementary Note on the Red Rocks of the Devon Coast-Section."

THURSDAY, Nov. 26...London Institution, Finsbury-circus, E.C., 6 p.m. Prof. Boyd Dawkins, "The Spread of Commerce in Europe in Pre-historic Times."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on paper by Capt. H. R. Sankey and Mr. F. V. Anderson, "Description of the Standard Volt and Ampere Meter, used at the Ferry Works, Thames Ditton."

FRIDAY, Nov. 27....Juuior Engineering Society, Westminster Palace Hotel, S.W., 8 p.m. Presidential Address by Sir Edward J. Reed.

Civil Engineers, 25, Great George-street, S.W., 7½ p.m. (Students' Meeting.) Mr. Walter Clemence, "Modern Railway Carriages."

Journal of the Society of Arts.

No. 2,036. Vol. XL.

FRIDAY, NOVEMBER 27, 1891.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

TYPOLOGICAL MUSEUMS.

Attention is drawn to the alteration which has been made in the announcement of the Meeting for Wednesday, December 16. General PITT RIVERS will read his paper on "Typological Museums, as exemplified by the Pitt Rivers Museum at Oxford," on that evening; and Professor VIVIAN B. LEWES'S paper on the "Spontaneous Ignition of Coal" will be read at an early Meeting after Christmas.

Chicago Exhibition, 1893.

Under date of the 27th August, 1891, Her Majesty was pleased to issue a Commission to the Council of the Society of Arts, authorising them to act as Commissioners for the Universal Exhibition, which, pursuant to an Act of Congress, and in accordance with a Proclamation made by the President of the United States of America, will be held at Chicago from May 1st to October 30th, 1893.

The Royal Commission are now prepared to receive applications from artists, manufacturers, and others desirous of taking part in the Exhibition, to afford them all necessary information, and to offer them all available facilities which they may desire for this purpose.

Such applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, not later than February 29th, 1892, and addressed to the Secretary, as above.

As the funds granted by H.M. Government will not suffice to defray all the expenses of the Section, it is necessary that they should be supplemented by payments from the exhibitors. A charge will therefore be made to each exhibitor, based on the amount of space occupied, and calculated on the following scale:—

	Per sq. ft. s.	d.
For spaces not exceeding 100 sq. ft. ..	5	0
For spaces exceeding 100 sq. ft. and not exceeding 200 sq. ft.	4	6
For spaces exceeding 200 sq. ft. and not exceeding 300 sq. ft.	4	0
For spaces exceeding 300 sq. ft. and not exceeding 500 sq. ft.	3	6
For spaces exceeding 500 sq. ft. and not exceeding 750 sq. ft.	3	0
For spaces exceeding 750 sq. ft. and upwards	2	6

The minimum charge will be £5.

It is not expected that the total receipts from all sources will more than suffice to defray the cost of an adequate representation of British industry; but should there be a sufficient surplus after the payment of all the costs of the Section, the Royal Commission will refund the balance *pro rata* with the amounts contributed by the several exhibitors. The amount produced by the payments of exhibitors will therefore be treated as a guarantee fund, to be expended if necessary, but if not, to be refunded to the contributors.

The Exhibition is situated in Jackson-park, within the southern limits of the city of Chicago. The principal buildings are devoted to the following main divisions:—(1) Fine Arts; (2) Manufactures and Liberal Arts; (3) Agriculture; (4) Machinery; (5) Electricity; (6) Mines; (7) Transportation; (8) Horticulture. In all these, space has been allotted to Great Britain, though it is expected that the principal British Court will be that in the Building of Manufactures and Liberal Arts, since the privilege has been conceded to this country of massing all or most of its exhibits together, should such a course prove desirable.

Exhibitors' goods will be transmitted direct in bond to Chicago, where the usual Customs examination will be made. Goods for exhibition only will not be liable to duty, but on goods sold the usual rates will have to be paid. Goods can be sold in bond, at prices independent of the tariff, the duties being payable by the purchaser.

The American railroad companies propose

to carry goods back from the Exhibition free, charging the usual rates for the outgoing journey. These rates, it may be noted, are low in comparison with those usual in European countries. It is hoped that special terms for Exhibition goods traffic may be obtained from the Atlantic steamship companies. Full information as to routes, traffic, rates, &c., will be provided in due course.

A limited quantity of steam and water power will be supplied gratuitously. Further supplies will be provided at a fixed rate. Countershafts, pulleys, belts, &c., must be provided by the exhibitor. Application for motive power must be made on special forms, which will be supplied on demand.

The general reception of articles at the Exhibition buildings will commence on November 1, 1892, and no articles will be admitted after April 10, 1893. Foundations for heavy machinery may be put in, and special constructive work commenced, as soon as the state of the ground and the buildings permits.

The Royal Commission are informed that the contract labour laws of the United States will not prevent exhibitors from importing foreign labour, or from entering into binding contracts with their *employés*. Further information on this head will be supplied on application.

Every person who becomes an exhibitor in the British Section thereby agrees to be governed by the rules and regulations laid down by the Exhibition Executive, or by the Royal Commission through its executive officer.

Proceedings of the Society.

SECOND ORDINARY MEETING.

Wednesday, November 25, 1891; Professor GEORGE CAREY FOSTER, F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Baird, John, Knoydart, Isle Ornsay, N.B.
Brettell, J. Henry, 11, Portman-street, W.
Butterworth, William, United States Patent-office, Washington.
Patterson, Myles, Oriental Club, Hanover-square, W.
Proctor-Sims, Richard, M.Inst.C.E., Bhavnagar, Kathiawar, India.
Wilson, James, M.E., Old Forge, Dunmurry, Co. Antrim.

The paper read was—

THE MEASUREMENT OF LENSES.

BY PROFESSOR SILVANUS P. THOMPSON, D.Sc., F.R.S.

Often have I regretted that the resources at the disposal of the Technical College, Finsbury, did not enable its staff to organise and equip a proper laboratory for optical measurements, and for the standardising of optical instruments, in the same thorough and practical way in which they have now for more than ten years organised laboratories for electrical measurements. What Professor Ayrton did ten years back for the City and Guilds Institute, in organising a laboratory for electrical measurements, I have longed to do for optical measurement, believing that, when the opportunity should come, the work would be of as much benefit to the optical industries of London as the electrical laboratories of the City and Guilds Institute have been.

The exact measurement of optical quantities is no novelty: for in this branch of science precision has long reigned, if not in the lower branches of the industry, at least in the higher. And the laboratory methods of optical measurement are for the most part thoroughly worked out and known, though many of them unfortunately involve the use of expensive instruments and appliances.

An optical laboratory should possess the means of testing rapidly, accurately, and without too expensive appliances, such matters as the truth of plane surfaces, the curvature of curved ones, the focal powers of lenses, their aberrations and their aperture. It should have means of testing mirrors and prisms, as well as actual entire instruments. It should be able to state the results in terms available for future years by the employment of accurate fundamental standards.

With but one very small part of the subject of the work of the optical laboratory do I propose to deal to-night, namely, with the measurement of lenses. Lenses are used for many different purposes, and in varied functions and combinations. Measurements that would be important for some of these are utterly unimportant for others. For example, the condenser lenses used for magic lanterns are not wanted to be either aplanatic, achromatic, or rectilinear; their function being merely to collect the light which emanates from a certain luminous patch, and spread it as nearly equally as possible over the area covered by the trans-

parent slide, so that the whole is equally illuminated, and so that the light so transmitted shall be on the whole slightly convergent. To measure the aberrations or exact focal powers of such lenses would be a useless work.

However, it will be convenient at the outset to enumerate all the things which might be made the subject of measurement with respect to a lens or combination of lenses. These are no fewer than 18 in number:—

1. Diameter, or linear aperture.
2. Thickness, or length from pole to pole.
3. Focal power, or its reciprocal the focal length.
4. Position of principal focal planes.
5. Position of optical centres ("principal points" of Gauss).
6. Angular aperture.
7. Chromatic aberration.
8. Spherical aberrations, lateral and longitudinal.
9. Chromatic difference of the spherical aberration.
10. Loss of light by reflexion from surfaces.
11. Absorption of light in transmission.
12. Illumination of field, central and marginal.
13. Complaneity of focus (included in 7 and 8).
14. Degree of distortion of image (rectilinearity).
15. Cylindricity, or degree of astigmatism, including angle of axis of cylindricity.
16. Accuracy of centreing.
17. Definition in margin of field (involved in 7, 8 and 16).
18. Refractive indices of materials.

Now, of all these varied matters, there are but three with which the present paper will deal: namely, the focal power of lenses, and the position of their focal planes and principal points.

By focal power I mean, of course, that property on which their convergivity (positive or negative) depends, and on which in turn their magnifying (or minifying) action is dependent. It must be borne in mind, as a fundamental principle of elementary optics, that all that any lens or mirror (or combination of mirrors or lenses) can effect is to imprint a curvature on the wave-front of the light that enters it. If the wave is plane—*i.e.*, consists of parallel rays, to use the old language—then the lens prints a curvature, positive or negative, upon it by virtue of which its march is changed, and made convergent or divergent. If the wave before impinging on the lens is initially non-plane, but either convergent or divergent, then the lens will alter the curvature of the surface, the resultant curvature on emerging being simply the algebraic sum of the initial curvature and the impressed curvature.*

The focal power is the curvature imprinted by the lens on a plane wave, and is the reciprocal of the true focal length. It is appropriately expressed in terms of the proper unit of focal curvature, the *dioptrie*.† The proper numbering of lenses in dioptries has been an enormous gain in one branch of the optical industries—that of the ophthalmists—and it is much to be wished that other lenses than those of spectacles should also be henceforth described in the same way.

Another important step has been the introduction of the conception of focal planes—a conception to which the use of the photographic camera has doubtless contributed its share. Less fully recognised, but none the less important, is the conception introduced by Gauss as the result of his studies in geometrical optics, that the properties of any centred combination of lenses might be represented by a system of planes and points which are, so to speak, the characteristics of the equivalent lens. A lens can be considered as having a single optical centre only when it is infinitely thin, or at least of negligible thickness. All thick lenses and combinations of lenses have two optical centres, described by Gauss as the two "principal" points ("Hauptpunkte"), which are considered as the places where the axis intersects two "principal planes." These principal planes are at a certain distance apart, and equi-distant between the two principal foci

* All the ordinary formulæ of the text-books for lenses are more or less particular statements in symbols of this general rule: for example, the well-known formula

$$\frac{1}{v} = \frac{1}{u} + \frac{1}{f}$$

in which f is the focal length, and u and v the respective distances of two conjugate points serving as object and image. The reciprocal of a length *is* a curvature: so that this formula merely states that one curvature is the result of adding two other curvatures together. I have pointed this out in a paper in the *Philosophical Magazine*, in Oct., 1889.

† The *dioptrie*, originally proposed by Monoyer as the unit of focal power of a lens, is now in international use, having been formally adopted by the International Medical Congress at Brussels. It is a unit of curvature, and as such may be used for other purposes than focal powers—for example, to express the curvatures of surfaces. Unit curvature is taken as the curvature of a circle of one metre radius. Or a lens having a metre focal length is described in modern language as having a power of one dioptrie. A lens having half a metre as focal length has a power of two dioptries.

at the back and front of the lens. They possess certain properties most useful in the geometrical treatment of lens problems, and act as though the light, however obliquely it may be crossing the lens, were transferred straight from one to the other. The two "principal" points, or optical centres, possess the property that light proceeding from any direction towards the one of these points passes out from the lens combination as though it had passed through the other. Fig. 1 shows a

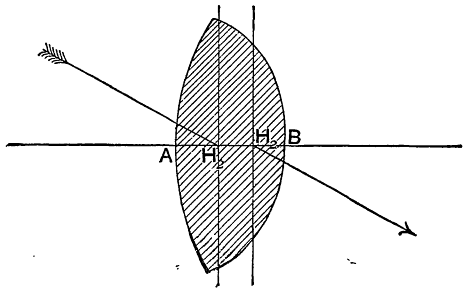

FIG. 1.

thick lens (in diagram), in which the two principal points of Gauss are marked H_1 and H_2, with the two principal planes drawn through them. These two points, together with the two principal foci, completely determine the action of the lens. When the positions of these four* cardinal points are known for any lens or lens-system, then all is known that is necessary for a complete discussion of the formation of images for all objects lying near the principal axis. The true focal length is the distance from either of the two principal planes to the corresponding principal focus; the back focus and the front focus being equidistant each from its own optical centre. But hitherto it has been found difficult to ascertain the position of the principal planes of a lens combination. Optical instrument makers generally have no information on the subject that they can furnish. They can tell us approximately the focal length, but they cannot, or do not, tell us the position of the optical centres or principal points from which this focal length is to be reckoned. Beginners in microscopic work, when they come upon an objective marked "¼-inch," expect to find that the object must be placed ¼-inch below the front surface of

* If the lens system is not bounded by similar media on its two faces—for example, if one side is bounded by air and the other by water—the two optical centres are shifted away from the two principal planes towards the denser medium, and are known as "nodal" points. In this case there are six cardinal points to consider.

the lens, and are often puzzled to find that the distance is perhaps only 1-10th inch. Naturally they ask the question, from what point does the maker measure his quarter of an inch? The correct answer is that the ¼-inch should be measured from the principal plane which corresponds to the front focus of the lens. But where this principal plane lies is never marked on the brass mount of the lens, though it ought to be. Again, the beginner often asks what is the correct way to reckon the true tube length of the microscope between objective and eyepiece. Must he measure from the lowest point of the eyepiece to the highest point of the objective, or how? The right answer is that the true distance between objective and eyepiece is not the mere length of the tube, but is the distance between the second principal plane of the objective, and the first principal plane of the eyepiece. But how is the unfortunate possessor of the instrument to measure this if the constructor has omitted to mark on the eyepieces and objectives the positions of the principal planes?

It is one of the purposes of this paper to describe an instrument for measuring lenses, and ascertaining the precise position of these principal planes. Therefore, a few more preliminary words about the principal planes and the two Gauss-points through which they pass, will be appropriate.

In ordinary single lenses, if not very thick in proportion to diameter, the distance between the two principal planes is approximately one-third of the thickness of the lens at its middle. Exact formulæ are given in various modern treatises on geometrical optics. In lenses that have their two faces of different curvatures the principal planes do not lie symmetrically between the two poles* of the lens, but are shifted toward the more highly curved face, or even beyond it. In plano lenses, whether convex or concave, one of the two principal planes is a tangent to the curved face. These matters are illustrated by the sketches in Figs. 2, 3, and 4 (p. 25).

If the positions of the four cardinal points are known for any two lenses separately, then, when the lenses are placed at any given distance apart, the positions can be found for the four cardinal points of the combination. The geometrical construction is very simple, and is illustrated in Fig. 5. Let h_1 h_2 be the

* I have used this term for years to denote the middle-points of the two faces of the lens, and find it very convenient.

two principal points of a lens, and f its principal focus for light passing through it to the right. Let $h'_1\ h'_2$ be those of a second lens, and let f' be its principal focus for light passing the other way. It is required to find the position of the principal points and of the principal focus of the equivalent lens. Consider any ray-path $a\ b$ parallel to the axis. Light travelling along from a will, after passing the principal planes of the first lens, turn towards f. Similarly, light passing the other way from b, after passing the second lens, will turn toward f'. These paths cross at o. Join oh_2 and oh_1; and draw $h_1\ x$ parallel to oh_2; and $h'_1\ y$ parallel to oh'_1. The planes xH$_1$ and

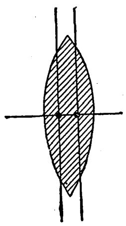

FIG. 2.

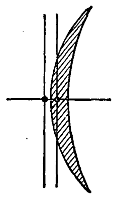

FIG. 3.

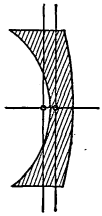

FIG. 4.

yH$_2$ drawn through x and y will be the desired principal planes. And the resultant focus **F** is found by considering the ray which starts from a and passes through o towards f, and remembering that, as it passes through the second lens, it will be shifted forward through the distance between the planes $h'_1\ h'_2$, and turned as though it came from y. A little consideration will show that if the two lenses were close together the width H$_1$ H$_2$ will be the sum of the widths $h_1\ h_2$ and $h'_1\ h'_2$; whilst if the two lenses are moved wider apart H$_1$ and H$_2$ will come nearer together, and may even cross past one another. If the lenses are placed at a distance apart equal to the sum of their focal lengths, H$_1$ and H$_2$ will not only have crossed planes, but will have separated to an infinite distance apart.

The formulæ for calculating the resultant focal length and resultant width between the principal points for a combination of two lenses at a distance apart, are as follows:—

$$\textit{resultant}\ f = \frac{f_1 f_2}{f_1 + f_2 - a};$$

$$\textit{resultant}\ w = w_1 + w_2 - \frac{a^2}{f_1 + f_2 - a};$$

where a is the distance between the lenses, f_1 and f_2 their focal lengths, w_1 and w_2 the widths between their principal points.

From these formulæ it follows that the resultant focal length of a combination of two positive lenses when separated by an interval is always greater than the reciprocal of the

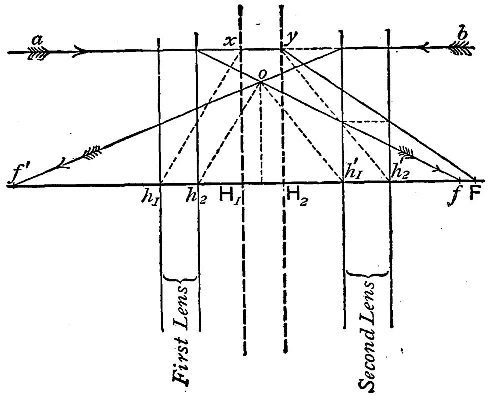

FIG. 5.

sum of their reciprocals, and increases as the lenses are separated. The resultant width between the principal points decreases from the value $w_1 + w_2$ down to nothing, and then increases negatively, becoming infinite when $a = f_1 + f_2$, and again becoming positive and finite when a exceeds that value.

If the optical combination is not achromatic, then the positions both of principal planes and of principal foci will be, in general, different for lights of different colours.

There exists yet another pair of points and planes, having special properties that should be noted. These are the points situated on the axis beyond the principal foci at distances respectively equal to the true focal length on either side. They are marked 1 and S$_2$ in Fig 6, being conjugate and symmetrically

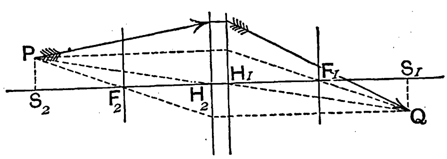

FIG. 6.

situated. Toepler, who first called attention to these two points, called them by the not very apt name of negative principal points (negative Hauptpunkte). I call them the two *symmetric* points, and the planes through them the *symmetric* planes. They possess the very useful properties that any object in one has an image of equal size, inverted, in the other, and that any ray which crosses one of them at any distance from the axis will, after traversing the lens, cross the other symmetric plane at an exactly equal distance from the axis, but on the other side of the latter.

I have now cleared the way for discussing the methods that have been hitherto used or suggested for measuring the focal properties of lenses. Unfortunately, most of the ordinary methods of focometry which are in accepted use are based on the assumption that the lens may be treated as of negligible thickness, and in some others one has to make assumptions beforehand as to the probable width between the principal planes. This is easy enough in the case of a single lens, but for compound lenses the principal planes come in most unexpected positions, at an unknown width apart. After I have enumerated the methods of focometry, and briefly described each, I will describe a new method, and an instrument for carrying it out.

METHODS OF FOCOMETRY.

The methods of focometry may be classified under six general heads; and under these may be grouped the several varieties adopted by different authorities.

I.—METHODS OF DIRECT FOCAL SEARCH.

(*a.*) *Objective Methods.*—The classic simple method of ascertaining the principal focus of a lens or optical combination, applicable only to positive lenses; consisting in sending rays from any very distant object through the lens, and searching for the real image which is received upon a suitable surface, preferably that of a semi-transparent screen.

(*b.*) *Berger's* Method.*—A variety of the preceding, in which an illuminated object and a collimating telescope at a finite distance are substituted for an indefinitely distant object, and the real image at the principal focus is sought by means of an observing microscope.

(*c.*) *Maskelyne's*† *Method.*—A telescope, fitted with crosswire eyepiece, is focussed upon an object at indefinite distance. The (positive) lens under examination being then clamped over the object-glass, it is pointed to a near object, which is moved to such a position as will give an accurate image in the telescope, the position of the object being that of the principal focus of the lens.

(*d.*) *Merz's*‡ *Method.*—A variety of the preceding, adapted to negative lenses. The telescope, with the lens under examination fitted in front of the object-glass, is focussed upon an object at an indefinite distance, and then the lens being removed, is pointed to a near object which is moved to a position giving accurate focus.

(*e.*) *Kerber's* Method.*—The positive lens being placed in front of an illuminated slit, it is moved to such a position that a slab of glass with parallel faces introduced into the path of the emerged rays produces, on being tilted, no change in the apparent position of the slit as viewed in a telescope; this being a test of parallelism of the rays.

None of the foregoing methods are applicable to very short focus lenses, and they give no information as to the Gauss points.

(*f.*) *Pendlebury's*† *Method.*—The positions of each of the two principal foci are found objectively, and then the respective distances are found from these to two conjugate points by inserting a luminous object and finding, objectively, its image. Then calling these two distances p and q, the true focal length is found by Newton's rule as a geometrical mean between them. After this calculation has been made, the distance between the two principal points can be found by subtracting twice the true focal length from the distance between the two principal foci.

II.—METHODS OF MAGNIFICATION.

(*g.*) *Ramsden's Method.*—Measurement is made of the size and distance of the real image formed at the conjugate focus of an object of known size, at known distance: and from these the focal depth is calculated. This method assumes the lens to be of negligible thickness.

(*h.*) *Meyerstein's* ‡ *Method.*—This is a modification of Ramsden's method to meet the case of thick lenses. The lens is placed between an object and a screen fixed at more than four times the focal length apart. Measurement is made of the size of object and image, together with their distance apart, and the distance of the lens from one of them. The lens is then reversed end for end, and is displaced longitudinally until the same magnification is obtained as before on the same

screen. All assumptions about the Gauss points are thus eliminated, for it is clear that if in the second observation, after reversing the lens, the same magnification is obtained as in the first, the second principal point now occupies the position which the first principal point previously occupied, and *vice-versâ*. From the magnification, the distance between object and image, and the measurements of the displacement of the lens, the true focal length is calculated. Dr. Meyerstein describes a special instrument for carrying out this method. This method was devised in 1844, but not published until 1877, after the same principle had been independently discovered and described by Dr. Hoppe.*

(*i.*) *Hansen's*† *Method.*—An object of given size being chosen, the positions of the lens are found which give (real) images of linear magnitudes respectively equal to that of the object multiplied by 1, 2, 3, &c; and from two (or more) of such observations, each of which requires a series of double adjustings, the focal length and the distance between the principal points are calculated.

(*j.*) *Mergier's*‡ *Method.*—This is an elegant mode of carrying out one of Hansen's suggestions. The two symmetric points are found by trial and double adjustment, as in Silbermann's method mentioned below, the magnification here being unity. Two micrometers serve as respecting object and as receptive surface for the image. This adjustment being made, then, in order to produce an image in the same place as previously but of double magnitude, it is sufficient to displace the lens through a distance equal to the focal length, and the object though exactly half this distance. This is accomplished by simple mechanical means, with two screws connected by wheel-gearing.

III.—Methods of Unit Magnification.

These methods constitute a special case of II., but are quite distinctive.

(*k.*) *Silbermann's*§ *Method.*—In this method the lens (positive) is placed at the middle of a graduated bench, upon which two transparent micrometers are placed on either side, so that the image of one micrometer falls upon the other. By a well-known theorem, the total distance between object and image will be a minimum, when the distance between them is equal to four times the focal length, and each is situated at one of the symmetric points of the lens. The operation of finding these symmetric points consists, then, in a series of double adjustments of the following kind:—One of the micrometers being placed at a distance judged approximately as twice the focal length, the second micrometer is then moved, until upon its surface an exact image of the first is formed. If, on comparing the size of the divisions of this image with those of the surface on which it falls, it is found that they do not coincide, but are either magnified or minified, the distance of the first micrometer is either increased or diminished, and the second micrometer is again adjusted to the new position of the image, and a fresh comparison made. By successive trials and approximations the symmetric points are approached; and, when so found, the distance between them is measured, and one-fourth of it taken as the focal length. The method is open to the objections (1) that it is inapplicable to thick lenses, as it does not take into account the distance between the Gauss points, and (2) that it requires a tiresome series of double adjustments. The simple modification of this method, suggested by Webb,* needs no notice here.

(*l.*) *Donders'*† *Method.*—Donders improved the method of unit magnification by substituting for the series of double adjustments a simpler mode of equalizing the size of object and image. He used as object an opaque screen provided with perforations, the linear dimensions of which from one to another were measured with a Helmholtz's ophthalmometer. The lens to be measured being placed in front of this object, an image is then formed on a translucent screen, and the lens is then moved to increasing distances until the size of the image, as measured by the ophthalmometer, is equal to that of the object.

(*m.*) *Snellen's*‡ *Method.*—This method,

‡ Snellen.—De Phakometer, ter repaling van focus en centrum van lenzen. *Maandblad voor Natuurwetenschappen*, vii. 1876, p. 23.

which closely resembles that of Donders, is carried out by the aid of an instrument called a *Phakometer*, consisting of a graduated bench at the middle of which the lens is placed. No ophthalmometer is used to measure the sizes of object and image, a translucent screen figured with marks serving to detect any want of equality between the sizes of image and object. It is assumed that the lens has a single optical centre at its centre of figure, and a mechanical adjustment serves to move the object and the screen at equal rates from the lens at the centre. The scale is divided to read off direct in *dioptries* the focal power of the lens. Snellen applies the method to negative lenses and long-focus positive lenses by placing them between two positive lenses of equal and known focal power; and in the case of plano-convex and meniscus lenses, he recommends that to secure symmetry, such lenses should be taken in pairs, back to back, and measured together.

IV.—Methods of Approximate Unit Magnification.

(*n.*) *Bessel's* Method.*—In this method the object and the apparatus to receive the image are placed at a distance from one another, exceeding four times the focal length, and the (positive) lens is placed between them. Two such positions of the lens can be found for either of which the distance between the two conjugate foci is the same. Bessel gives a formula for deducing the focal length from the measurements of the various distances. The method assumes the distance between the Gauss points to be known beforehand, and therefore fails to give any information on the more difficult point to be determined. The advantages of the method are that no measurements have to be made from the curved faces of the lenses, and that none have to be made of the sizes of optical images.

(*o.*) *Oudemans'*† *Method* is simply the method of Bessel carried out by means of a special apparatus, consisting of a simple graduated bench, and hair micrometers. Oudemans gives approximate formulæ for calculating the distance between the Gauss points, for insertion in Bessel's formulæ, but confesses that this procedure fails in the case of many lens-combinations.

* Bessel.—*Astronomische Untersuchungen*, vol. i. p. 137.

† Oudemans.—Sur la détermination des distances focales des lentilles à court foyer. *Archives Néerlandaises*, t. xiii. 1877, p. 149.

(*p.*) *Hasselberg's* Method.*—In applying Bessel's plan, Hasselberg employs as objects the real images of spectrum lines as formed in the focal plane of the eyepiece of a spectroscope. He compares to some hundredths of a millimetre, the performance of a Zeiss's objective constructed of ordinary glass, but assumes the Gauss points by approximate calculation.

(*q.*) *MacGillavry's*† *Method.*—This elegant method departs from Bessel's in that it requires measurements to be made of the respective sizes of object and image, as well as of the distance between them, and of the displacement of the lens between the two intermediate positions of adjustment to exact focus. But by this means all assumptions or estimates about the distance between the Gauss points are avoided. MacGillavry gives three formulæ from each of which this unknown quantity has disappeared by elimination; the true focal length being given in terms of the quantities directly measured, namely, from the relative sizes of object and image in the two positions, and the change in any one of the three measured lengths. Apart from the experimental difficulty of accurately measuring the magnification, MacGillavry's method appears to be very satisfactory.

V.—Method of Approximate Interior Unit Magnification.

(*r.*) *Cornu's*‡ *Method.*—This is one of a group of possible methods in which the respective distances from their related principal foci of two conjugated points are measured, and the true focal length (which is their geometrical mean) is calculated from them; the peculiarity of Cornu's plan being that the two conjugate points employed are close to the two Gauss points, one of them being always interior to the lens. The lens is temporarily marked with ink-lines upon its faces, and the experimental process consists in observing by a reading microscope of sufficiently long focus the positions in space of the principal focus of the lens, the marks on the nearer face, and the internal vertical image of the marks on the further face. From the distances thus measured, together with a measurement of the

thickness of the lens, the true focal length, as well as the distance between the Gauss points, can then be calculated. In practice, the direct measurement of the thickness of the lens is avoided by the device of reversing the position of the lens and repeating the three readings from the reversed faces. M. Cornu describes an apparatus constructed for him by Duboscq for carrying out these measurements.

(*s.*) *Mebius'* Method.*—This is a modification of the method of Cornu for the particular case of negative lenses, and needs no extended notice here.

VI.—Method of Obliquity of Rays.

(*t.*) *Moser's† Method.*—This method is based on the principle that any ray which on entrance passes through the first Gauss point at any given obliquity with respect to the principle axis emerges with unchanged obliquity, but displaced, as if it had passed through the second Gauss point. To determine these points the experimental process consists in a series of approximations derived from measurement made of the magnification.

Of the various methods thus briefly reviewed, only those of Pendlebury, Meyerstein, MacGillavry, and Cornu fulfil the conditions of determining the values of both f and κ without double adjustments. Doubtless, each has its advantages for particular cases. Yet it appeared worth while to follow out another method which seemed to possess some advantages over any yet suggested.

A New Focometric Method.

In the new method of focometry which the author has devised, direct methods of measurement of lengths only are used; and double adjustments are avoided. The method consists in the direct determination, *firstly*, of the two principal foci by placing a transparent micrometric screen at each; and, *secondly*, when these have been found, the two symmetric points by moving the two screens by a double screw motion through equal distances until each is the image of the other. The true focal length (f) and the distance (κ) between the Gauss points are therefore given by simple subtraction of scale readings.

Choice of the Symmetric Points.

It is easy to show that in any determination of focal lengths, the most favourable position for an experimental measure of any two conjugate points is when these occupy the symmetric points; provided the experimental determination of the two conjugated foci, is *assumed* to be of equal difficulty.

Let p and $-q$ be the respective distances of the point-object and point-image from the two corresponding principal foci. Then by Newton's rule, we shall have

$$f^2 = pq\,; \quad .. \quad .. \quad .. \quad .. \quad .. \quad (1)$$

where f is the true principal focal length.

If in the determination of the lengths p and q we make errors of measurement, respectively Δp and Δq, there will result an error of Δf in the calculation of the focal length, having a value determined by the equation—

$$(f+\Delta f)^2 = (p+\Delta p)\,(q+\Delta q), \quad .. \quad (2)$$

Or—

$$f^2 + 2f\Delta f + \Delta^2 f = pq + p\Delta q + q\Delta p + \Delta p\Delta q \quad .. \quad .. \quad .. \quad .. \quad (3)$$

Subtracting (1) from (3) and neglecting small quantities of the second order, we have:—

$$2f\Delta f = p\Delta q + q\Delta p \quad .. \quad .. \quad .. \quad .. \quad (4)$$

Hence, divided by $f^2 = q$ we get:—

$$\frac{\Delta f}{f} = \frac{1}{2}\frac{\Delta q}{q} + \frac{\Delta p}{p} \quad .. \quad .. \quad .. \quad .. \quad .. \quad (5)$$

or the per-centage error in f is the mean of the per-centage errors in p and q. Hence, since Δp and Δq are obviously of the same order of magnitude, if we write Δm for the arithmetical mean of them, and assume that each of them is equal to this value, we get from (4)—

$$\Delta f = \frac{1}{2}\,\frac{p+q}{f}\,\Delta m \quad ... \quad ... \quad ... \quad (6)$$

which shows that for a given mean error Δm and a given focal length, the error made in determining this focal length will be proportional to $p + q$. Hence those values of p and q which make $p + q$ a minimum will make the error Δf a minimum. And, as $pq = f^2$ is a constant for a given lens, it is obvious that the case of minimum value of $p + q$ is when $p = q$; this being the case when the conjugate points are at the symmetric points.

The assumption made above that the experimental difficulty of determining the position of a conjugate focus is equal for conjugate foci in any position, is, however, hardly justified in practice, for in all laboratory experience it is admitted that it is more difficult to ascertain with precision the position of an image (real)

* Mebius.—Détermination expérimentale des éléments principaux d'une lentille divergente. *Journal de Physique*, 2me Série, ix., p. 511.

† Moser.—Methode die Brennweite und optischen Hauptpunkte von Linsen zu bestimmen. *Pogg. Annalen*, lxiii., 1884, p. 39.

which is remote from a lens than that of one near the lens. In fact, the experimental location of the image is mainly delimited by the sharpness of the crossing of the rays, and the tangent of the angle at which the extreme rays cross is inversely proportional to the distance from the lens. The aperture of the lens then limits the accuracy of determination of foci at great distances. The larger the aperture the more accurately (assuming spherical aberration above) will be the delimitation of the foci; but the larger the aperture, the greater do spherical aberrations become. The error in determining q may arise at either end of the measurement; it is more likely to occur at the end most distant from the lens than at the principal focus. If it be assumed that the probable magnitude of an error Δq made in estimating the value of q is proportional to the distance of this focus from the lens, then we may write Δq as proportional to $q + f$, and similarly Δp as proportional to $p + f$. Substituting these values in (4) we get:—

$$2f\Delta f \propto p(q+f) + q(p+f)$$

and, dividing by f and collecting, we get

$$\Delta f \propto f + \tfrac{1}{2}(p+q).$$

This is still a minimum (for positive values of p and q) when $p = q$, or when the conjugate foci are taken at the symmetric points.

Principle of Focometer for Determining the Focal Planes and Principal Planes of any given (Positive) Optical Combination, such as a Microscope Objective, or other Lens.

The abstract principle of this focometer was described as follows by the author two years ago, in a memorandum accompanying an application made to the Royal Society for a grant in aid of the construction of the apparatus:—

"Let A B (Fig. 7) be the objective (or

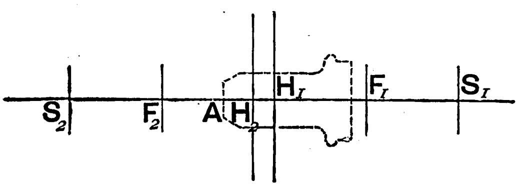

Fig. 7.

lens); H_1 H_2 its principal points: F_1 F_2 its principal foci; and S_1 S_2 the two symmetric points situated each at double the focal distance from the respective principal points S_1 S_2 are conjugate points, and the planes through them are planes of unit magnification.

"Suppose a parallel beam to be sent (from a lamp provided with a reticle in front of it and a collimating lens, all placed in air at some convenient distance away) through A B from left to right. An image will be formed at F_1, thus determining that point. Then, with the same source removed to a distant point on the right, send a parallel beam from right to left, thus determining F_2. Small glass plates, having micrometers cut on surfaces (respectively) nearest to H_1 H_2, and each provided with a reading lens behind, should be used to receive these images, and to ascertain their precise position in space. The said micrometers should be mounted on supports sliding along a suitable bench, over the middle of which the objective has been clamped in a special support. The micrometers, or, at least, one of them, should be so arranged that they can be thrown out of the axis laterally when not wanted. They should be provided with verniers to read off their positions on the bench. They should also be furnished with clamps, which, after each has been once set at its principal focus, will permit it to be clamped to a screw below on the bench. The distance from F_1 to F_2 is equal to $2f + x$ (where f is the true focal length and x the unknown distance between the two principal planes).

"Now, let there be a gearing, such as a right and left-handed screw, which will enable the observer to move the two micrometers from F_1 and F_2 at exactly equal rates outwards. When one of them arrives at S_1 the other will at the same moment arrive at S_2, and this will be known by observing through the reading lens attached to one micrometer the inverted image of the other, coincident, but reversed in position (exactly as in Silbermann's old form of Focometer). The equality of object and image in size—known by the fitting of the micrometer scales—will serve to check the correctness of the observation. The distance from S_1 to $S_2 = 4f + k$. Hence $k = 2F_1 F_2 - S_1 S_2$: and $f = F_1 S_2 = F_1 S_2$. By measuring off backwards from F_1 a distance equal to $S_1 F_2$, the point H_2 is arrived at. Similarly H_1 is arrived at, and these points can be marked off on the outside of the tube of the objective."

Description of the Instrument.

In accordance with the foregoing project, the author designed an instrument which he

terms a Focometer. It was constructed by Messrs. Nalder Bros., of Clerkenwell, to whom the author is indebted for many useful suggestions embodied in the apparatus. The construction is shown in the accompanying figures.

The support for the lens or combination of lenses to be examined is fixed at the middle of a bench made of two parallel girders of gun-metal, each 670 millimetres in length, placed vertically above one another, and secured together both at their ends and at the middle. The highest and lowest faces of this double girder are bevelled at 45°, and a scale of millimetres is divided along the front face at the upper edge. This girder frame is shown from the back in Fig. 8 (p. 32), in end view in Fig. 9. The support for the lens can be raised by a dovetail slide worked by a rack, or moved horizontally transversely to the bench by another dovetail slide furnished with a screw motion, as shown in Figs. 8 and 9.

The travelling supports for the micrometers are two solid pieces of brass, which fit over the bevelled edges of the girders and slide without any looseness of motion along the frame. Each bears a vernier to read off its position on the bench, and each is furnished at its upper point, as shown in Fig. 8, with a horizontal slide for fine adjustment, worked by means of a screw of fine pitch; the position of the horizontal slide being read off by means of a vernier against a short scale cut upon the face of the support. Except when the clamps described below are applied, each of these supports is so far free that it can be pushed along the bench by hand, but is fitted to slide so accurately that it cannot be shifted by any chance touch.

Between the parallel girders, running from end to end of the apparatus, is a double screw, the two halves being respectively right and left-handed, each accurately of a pitch of two millimetres. This screw, the function of which is to shift the two supports for the micrometers, is furnished at each end with a large milled head, and with a driving handle. The screw is of steel. It was constructed in two separate parts, which were then united by being securely rivetted into a short cylinder of steel of larger diameter. This cylinder runs through a bearing in the central piece of the frame of the instrument, and is secured in position between two fixed collars of steel, which are seen edgways in Fig. 8. These collars are screwed up sufficiently tightly to prevent any end play. At the two outer ends the screw passes through two bearings in the end supports, which admit of longitudinal play so as to allow for any difference of expansion between the screw and the frame of the instrument.

The manner in which the driving motion is communicated from the screw to the two travelling supports is peculiar. A device was needed which would admit of the travelling supports being independently moved to any positions when not clamped to the screw, and of being clamped in any position to the screw, so as to be driven by it without backlash. These conditions were finally fulfilled in the following manner. Upon each half of the screw is placed a massive gun-metal nut, about 50 millimetres long, and of square section 25 millimetres in the side. The lower face of this nut slides upon the upper face of the lower girder, and this prevents it from turning; it is also prevented from turning by the interposition, between its upper face and the lower face of the upper girder, of a long slotted rectangular flange of brass which constitutes part of a clamping bar. Each nut is bored out with a short cylindrical cavity. Within this are inserted a spiral spring of steel wire, and a second nut which, though capable of longitudinal play, is prevented from turning by the insertion of a key into a key-way. The introduction of this second nut, with a strong spring between it and the main nut, is a mechanical device originally due to Sir William Thomson, P.R.S., for preventing back-lash. The slotted clamping-bars mentioned above are of brass, each 176 millimetres long. Each is, as may be seen from Figs. 8 and 9, of L-shaped section, fitting over, and in front of the square nut. The upper horizontal flange which comes between the top of the nut and the under side of the higher girder is of accurate fit, and is slotted out to receive beneath it the head of a clamping pin. This pin, passing vertically through a projecting lug of the travelling support, enters the threaded shaft of a clamp screw which bears at its top a milled head. When this is turned, the head of the clamping pin is raised and clamps the slotted bar to the lug of the travelling support. The vertically-situated flange of each of the L-shaped clamping bars fits accurately into the space between the upper and lower girders, and it also is slotted to admit through it a clamping pin which projects horizontally from the square nut. A clamping screw with milled head screws on to this pin, and clamps the slotted bar to the square nut. It is shown in Fig. 9

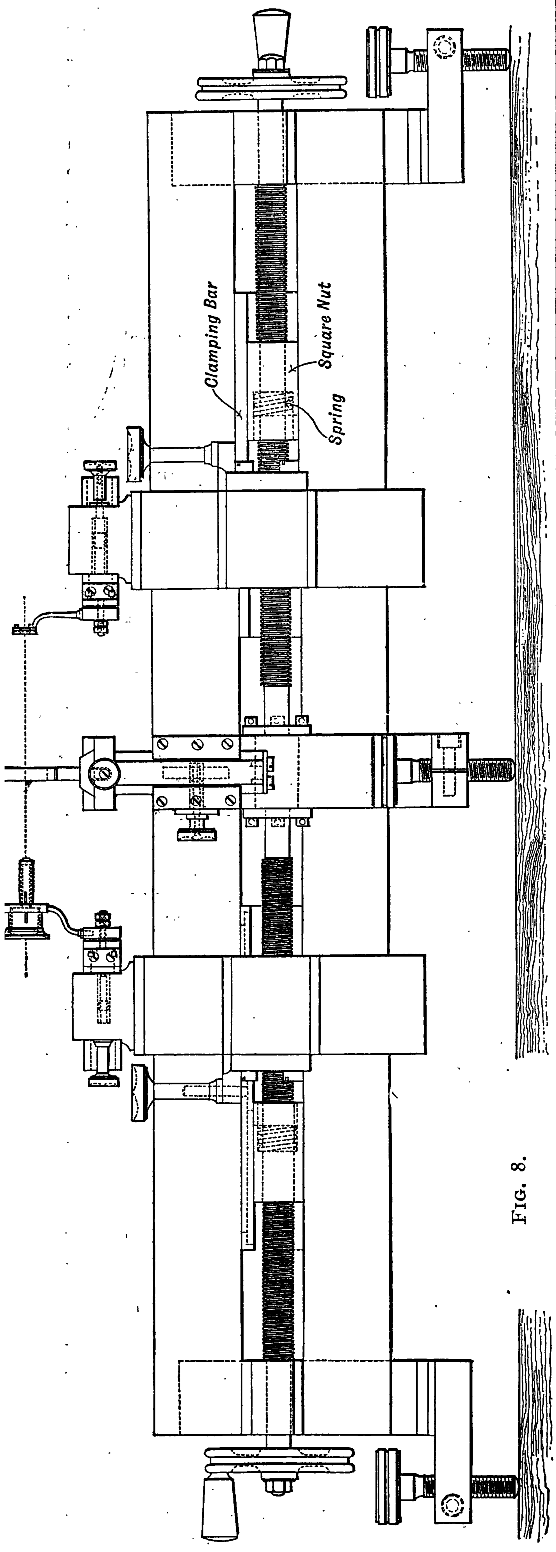

FIG. 8.

projecting to the left. In order that the turning of the long screw may drive the two travelling supports, it is requisite that each should be clamped to its slotted bar, and that each slotted bar should be clamped to the square nut. The object of using such long clamping bars instead of mere short pieces is to enable the travelling supports to be clamped when at unequal distances from the centre of the apparatus, the two square nuts being always situated symmetrically at equal distances from the centre.

The micrometers and other appliances for receiving the focal images are of three different kinds.

The first kind is shown on the left-hand support of Fig. 8. It consists of a small bevel-edged disk of glass, fixed in the

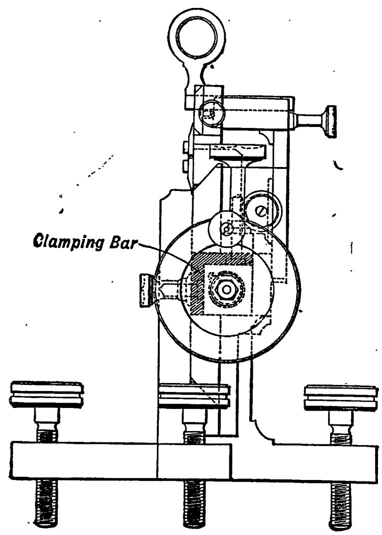

FIG. 9.

end of a narrow tube, and provided with a reading lens or positive eyepiece of about 38 millimetres' focal length. Upon the outer surface of the glass disk is ruled a scale divided into fifths of millimetres. This micrometric arrangement is convenient for receiving a focal image, as formed at the back of a microscopic objective, at a point at some distance down the tube in which the objective is mounted.

The second kind, shown in Fig. 8, on the right-hand support, consists of a rather larger disk of glass, mounted in a metal rim, which is cut away at two places. Upon the front face of this disk, a micrometer scale in fifths of millimetres is also ruled, and one half the disk is silvered over. This

arrangement is convenient for use with larger lenses, and for service as an object, in which case it is illuminated from behind. When making determinations of microscopic objectives it is found convenient to use one micrometer of the second kind opposite the front of the objective, and one of the first kind at the back of the objective; the pieces being mounted as shown in Fig. 8. Each of the micrometers can be shifted laterally out of the line of the lens under measurement, the arm which carries the micrometer being fastened to a collar furnished with a small handle, as shown in Figs. 8 and 9. This collar is guided to move in a plane orthogonally to the optical axis of the apparatus by an adjustment of three abutting screws. These three abutting screws are not shown in Fig. 9, but the heads of two of them are shown in profile in Fig. 8; being situated behind the collar bearing, which receives the curved supporting stem of each of the two micrometers. These bearing-collars are provided with stops to enable the micrometers to be brought up accurately to their former position after having been thrown out laterally.

A third arrangement, not shown in Fig. 8, is used only for large lenses, and consists of a grooved metallic ring mounted on a curved arm upon the top of the travelling support. Over this grooved ring is stretched a piece of thin paper, which, after having a millimetre scale marked upon it, is rendered nearly transparent by the application of varnish. Two such micrometers are used—one at either end—when measurements are to be made upon camera lenses, and other lenses having a focal length of several centimetres.

The holder, fitted upon the central support, as shown in Figs. 8 and 9, for carrying the lens, is cut with the Royal Microscopical Society's standard screw, so as to receive any microscopic objective. For other small lenses an adapter, provided with the same screw, is used, and the lens is temporarily fitted into the adapter by means of a cork ring. For large lenses a **V**-shaped appliance is substituted for the screw holder.

In order to know the position of the lens itself with respect to its focal and principal points, it is necessary to ascertain the scale-reading corresponding to some fixed point on the lens, or on its attached mounting. This might be done by end-measurement, by bringing one of the micrometers up into actual contact with one pole of the lens; but such a mode of proceeding is inadvisable for several reasons. It was therefore decided, when the instrument was being designed, to adopt such a construction as would permit of direct determinations by means of a delicate plumb-line. With this object, the general form of double girder was adopted, so that the scale might be engraved on the front of the vertical face. By reference to the end elevation in Fig. 9, it will be seen that the optical axis of the apparatus is arranged to be in the same vertical plane. Moreover, the micrometers are so arranged that in each case a plumb-line can be hung directly against the actual face of glass or paper upon which the micrometer is engraved. As plumb-line, a thin silk thread with a small leaden sphere at the end of it is used. When the instrument is properly levelled, the plumb-line can be applied to read off directly on the scale the actual position of any of the micrometers; and so by comparison with the readings of the verniers of the travelling supports is obtained the zero reading for use in future measurements.

It was consequently necessary to furnish the instrument with levelling screws. There, however, arose a small mechanical difficulty; for an instrument of this shape would not be very stable if provided with one foot at one end, and two near together at the other. It is therefore provided with four levelling screws, one at each end and two at the two ends of the central support. In practice, this arrangement is quite workable; and it is found convenient first to adjust the level of the girders lengthways by the end screws, then to adjust transversely by the other screws. The frame is so solidly made that there is no fear of racking it by unequal weight upon the four screws; the wooden top of a strong laboratory table is not so rigid as to make any fine adjustment necessary.

Mode of Using the Focometer.

The mode of procedure in using the instrument is as follows:—The lens to be measured having been secured in the central support, it is then adjusted in position so as to be accurately in the axial line between the two micrometers. The clamps of the two travelling supports are left loose, being only applied when required. One of the micrometers (in practice, that shown on the left in Fig. 8) is then thrown out laterally, and a beam of parallel light is thrown through the lens (from left to right, as seen in Fig. 1), so as to form an image at the first principal focus. In practice, this is done as follows:—A com-

pound lens, which is to be used as a collimator, is placed in direct sunlight, and at the focal point, where the image is formed, is placed a piece of ground glass, coarsely ruled with black lines. When this reticle is set in its exact position with respect to the collimating lens, the combination is placed at one end of a long room, about 40 feet long, with a paraffin lamp behind the reticle to illuminate it. The parallel beam thus issuing from the collimating lens is received on the focometer about 20 feet away.

The travelling support on the right (Fig. 8) is then brought up by hand and adjusted so that the micrometer is approximately at the principal focus. It is then clamped to the screw, and, using a positive eyepiece to aid the vision, the micrometer is accurately adjusted to the focus either by turning the main screw, or by the fine-motion screw on the travelling support This first adjustment having been made, the clamps are then unfastened, and the micrometer is thrown out laterally.

A parallel beam is then thrown in a similar fashion in the reverse direction through the lens, and the second micrometer is thrown into line and is brought by a similar process to the second principal focus.

The plumb-line is then applied to ascertain the position of some fixed point of the lens, and to read off the positions of the micrometers, which are replaced in their axial positions: or, if the zero readings of these are known, their positions are ascertained from the readings of their respective verniers.

These three readings having been made, both the travelling supports are clamped to their respective nuts on the main screw. The screw is turned so as to cause the micrometers to travel outwards. The observer, looking into the eyepiece of the micrometer on the left, sees an inverted image of the other micrometer come into view, and, as the screw is turned, the micrometers reach a certain position when both sets of dividing lines are in focus in the same field without any parallax. This position can be very accurately ascertained by shifting the eye slightly from side to side of the lens. The two micrometers now occupy the two symmetric points, and their positions are observed either by plumb-line, or by the readings of their respective verniers.

The simple method of calculating by subtraction of scale readings the true focal length, f, and the distance between the two Gauss points, has been given above.

RESULTS OF MEASUREMENTS MADE WITH THE FOCOMETER.

The following examples are given of measurements made on lenses. In all cases here recorded a red light was used, a ruby glass being interposed.

(1.) *Small Hemispherical Lens*, 12 millims. aperture, by Cooke and Sons.—Front of hemispherical face taken as point of reference, A. Preliminary experiments with plumb-line showed that F_2 is 76·1 millims. behind zero of of vernier Z_2, and F_1 is 49·6 millims. in front of zero vernier Z_1.

Readings of verniers for principal foci are:—

$$Z_1 = 356{\cdot}55 \qquad Z_2 = 199{\cdot}20$$
$$-76{\cdot}10 \qquad +49{\cdot}60$$
$$F_1 = 280{\cdot}45 \qquad F_2 = 248{\cdot}60$$

Readings of verniers for symmetric points are:—

$$Z'_1 = 371{\cdot}52 \qquad Z'_2 = 184{\cdot}17$$
$$-76{\cdot}10 \qquad +49{\cdot}60$$
$$S_1 = 295{\cdot}42 \qquad S_2 = 233{\cdot}77$$

$$f = \text{mean of } F_2 - S_2 \;\&\; S_1 - F_1 = \frac{15{\cdot}03 + 14{\cdot}97}{2}$$

$$f = 15{\cdot}0 \text{ millims.}; \; \mathfrak{F} = 66{\cdot}6 \text{ dioptries.}$$

$$\kappa = 2\,(F_1 - F_2) - (S_1 - S_2)$$
$$= 2{\cdot}05 \text{ millims.}$$

H_2 is at 263·6; H_1 at 265·65 of scale.

A is plumbed at 262·65. Hence first principal point is 0·95 millim. within the front of the hemispherical surface.

(2.) *Substage Condenser* (single lens), by Beck.—Flat upper face of lens taken as point of reference A:—

$$A = 251{\cdot}8$$
$$Z_1 = 356{\cdot}32\,; \quad Z_2 = 196{\cdot}5$$
$$-76{\cdot}1 \qquad +49{\cdot}6$$
$$F_1 = 280{\cdot}22 \qquad F_2 = 246{\cdot}1$$
$$Z'_1 = 370{\cdot}54 \qquad Z'_2 = 182{\cdot}17$$

f = mean of $Z'_1 - Z_1$ and $Z_2 - Z'_2$ = 14·28 millims.

$\mathfrak{F}$ = 65·4 dioptries.

$$H_1 = F_1 - f = 265{\cdot}94$$
$$H_2 = F_2 + f = 260{\cdot}38$$
$$\kappa = H_1 - H_1 = 5{\cdot}56 \text{ millims.}$$

(3.) *Coddington Lens*, reputed one-inch focal length.—Summit of one curved face taken as point of reference:—

$A = 265{\cdot}8$
$B = 280{\cdot}9$
$F_1 = 299{\cdot}3$; $F_2 = 247{\cdot}2$
$S_1 = 325{\cdot}6$ $S_2 = 220{\cdot}8$
$f =$ (mean of $S_1 - F_1$ and $F_2 - S_2$) $= 26{\cdot}35$
$\mathfrak{F} = 37{\cdot}95$ dioptries.
$H_1 = F_1 - f = 272{\cdot}95$
$H_2 = F_2 + f = 273{\cdot}55$
$\kappa = H_1 - H_2 = -0{\cdot}60$ millims.

The Gauss points are crossed, and close together.

(4.) *Objective* 1-*inch*, by R. and J. Beck.

A (front of lens) at 248·2.
$F_1 = 279{\cdot}88$
$F_2 = 241{\cdot}98$
$S_1 = 300{\cdot}09$
$S_2 = 221{\cdot}75$
$f = 20{\cdot}22$ millims.
$\mathfrak{F} = 49{\cdot}46$ dioptries.
$H_1 = 259{\cdot}67$
$H_2 = 262{\cdot}21$
$\kappa = H_1 - H_2 = -\ 2{\cdot}54$ (Gauss points crossed).

(5). *Objective* ¼-*inch*, by R. and J. Beck.—Back focus too deep in tube to use ordinary micrometer; used a 1½ inch objective instead, as auxilliary lens, to explore focus.

A (front of lens) at 252·4
$F_1 = 274{\cdot}88$
$F_2 = 252{\cdot}14$
$S_1 = 281{\cdot}20$
$S_2 = 246{\cdot}2$
$f = 6{\cdot}13$ millims.
$\mathfrak{F} = 163{\cdot}1$ dioptries.
$H_1 = 268{\cdot}75$
$H_2 = 258{\cdot}27$
$\kappa = H_1 - H_2 = 10{\cdot}48$ millims.

(6). *Objective reputed* 16 *mm.*, by Zeiss, ("apochromatic"). (Used auxiliary lens as in preceding for back focus.)

$A = 242$
$F_1 = 258{\cdot}61$
$F_2 = 239{\cdot}2$
$S_1 = 275{\cdot}04$
$S_2 = 222{\cdot}67$
$f = 16{\cdot}43$ millims.
$\mathfrak{F} = 60{\cdot}86$ dioptries.
$H_1 = 242{\cdot}18$
$H_2 = 255{\cdot}63$
$\kappa = -\ 13{\cdot}45$ millims. (Gauss points crossed.)

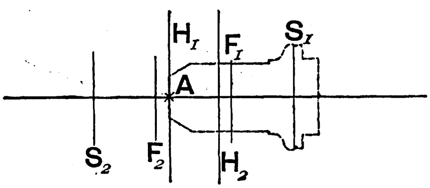

FIG. 10.—ZEISS'S OBJECTIVE.

(7.) *Objective reputed* 8 *mm.* by Reichert.

$A = 251{\cdot}35$
$F_1 = 256{\cdot}72$
$F_2 = 250{\cdot}85$
$S_1 = 263{\cdot}78$
$S_2 = 243{\cdot}79$
$f = 7{\cdot}06$ millims.
$\mathfrak{F} = 141{\cdot}6$ dioptries.
$H_1 = 249{\cdot}66$
$H_2 = 257{\cdot}91$
$\kappa = -\ 8{\cdot}25$ millims. (Gauss points crossed, and lie outside focal planes.)

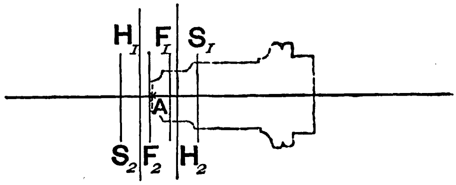

FIG. 11.—REICHERT'S OBJECTIVE.

(8.) *Camera Lens* (landscape), maker unknown.—A. taken at front of mount. All measures plumbed direct.

$A = 233{\cdot}9$
$F_1 = 417{\cdot}8$
$F_2 = 151{\cdot}0$
$S_1 = 547{\cdot}7$
$S_2 = 20\ 45$
$f = 130{\cdot}22$ millims.
$\mathfrak{F} = 7{\cdot}68$ dioptries.
$H_1 = 287{\cdot}58$
$H_2 = 281{\cdot}22$
$\kappa = 6{\cdot}36$ millims.

(9.) *Aplanatic Condenser for Lantern*, constructed by R. and J. Beck on Herschel's formula.—A. taken at front of mount on concave side.

$A = 237{\cdot}5$
$F_1 = 365{\cdot}5$
$F_2 = 193{\cdot}3$
$S_1 = 435{\cdot}7$
$S_2 = 121{\cdot}8$
$f = 71{\cdot}0$ millims.
$\mathfrak{F} = 14{\cdot}8$ dioptries.
$H_1 = 294{\cdot}2$
$H_2 = 264{\cdot}3$
$\kappa = 29{\cdot}9$ millims.

(10.) *Camera Lens* (small landscape), maker unknown.—A taken at rise of mount at front end.

$A = 247{\cdot}2$
$F_1 = 416{\cdot}2$
$F_2 = 136{\cdot}7$
$S_1 = 534{\cdot}2$
$S_2 = -1{\cdot}3$
$f = 138$ millims.
$\mathfrak{F} = 7{\cdot}248$ dioptries.
$H_1 = 278{\cdot}2$
$H_2 = 274{\cdot}7$
$\kappa = 3{\cdot}5$ millims.

No complete examination of any lens for rays of different colours has yet been made, but it

has been found that lens No. 4, examined above for red light, gives with green light a different value for κ, though the lens is sensibly achromatic at the principal focus.

The most interesting results obtained so far are the facts that in so many compound lenses the Gauss points are crossed, the first point being beyond the second. And, in the case of one lens (No. 7), a Reichert's objective, the distance between these two points is found to exceed the distance between the two principal foci. It seems to be a necessity with all wide-angled compound lenses that the aberrations can only be reduced to a minimum by widely separating the constituent lenses, with the result that the optical centres of the combined lens are considerably displaced past one another.

Since the bulk of the foregoing investigations were carried out, the authorities of the Kew Observatory have decided upon undertaking the testing of camera lenses, and issuing certificates of merit. In this work they have had the benefit of the advice of Captain Abney, F.R.S., than whom no one is better able to advise as to what is desired for photographic purposes. This is an excellent beginning, but it is curious that in neither of the certificates issued is any information given as to the position of the optical centres, or their distance apart. The "differences in focal length" for red and violet rays is given, but whether this means difference in true focal length, or difference in position of focal plane, is not stated. What a photographer wants is not agreement in focal length, but in focal plane, which is a very different matter. Also in the "A" certificate issued from Kew, it is proposed to state the optical distortion at 25° from the axis, "including astigmatism." But whether this means that the test is to include one for cylindricity so as to give the direction of the axis of astigmatism in the focal plane, or whether this term is being misused to denote spherical aberration, does not appear. Certainly no really astigmatic lens could be tolerated for an instant in photography, as it would result in all vertical lines being out of focus when all horizontal lines were in focus, or some similar defect.

I notice in a recent most admirable article on photographic lenses, in *Nature*, by Mr. A. Mallock, the term astigmatism is also used for the distance between the primary and secondary foci as produced by oblique rays. But this is not astigmatism at all, and has nothing to do with the cylindricity of the lens, the defect which produces astigmatism. What Mr. Mallock applies this term to is spherical aberration pure and simple.

I pointed out in 1889, in my article in the *Philosophical Magazine*, how the focal power of a lens is the product of a number depending

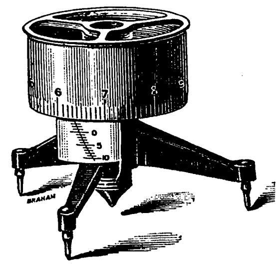

FIG. 12.

only on the properties of the material into the sum of the two curvatures of its faces, or, in the case of thick lenses, of a more complex quantity depending on the thickness of the lens as well as its curvatures. And in order to

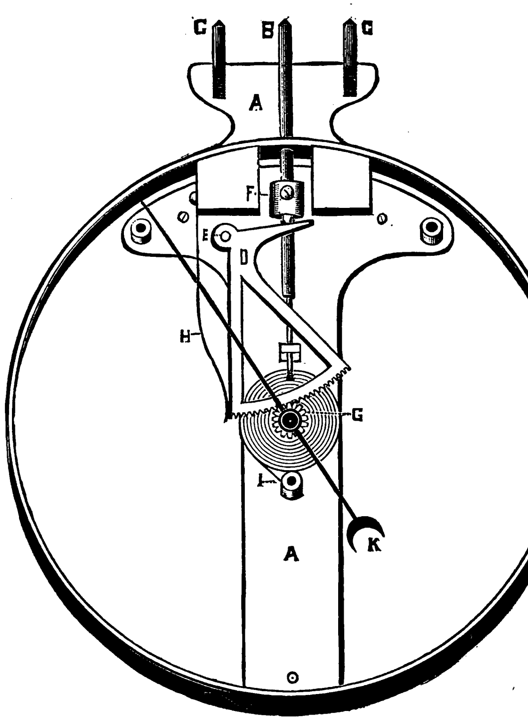

FIG. 13.

facilitate calculations I devised a special form of spherometer—the *dioptrie spherometer*—(Fig. 12) which measures the curvatures of the surfaces directly in dioptries. This was also constructed for me by Messrs. Nalder Bros. To apply this to any simple lens one merely takes

the two readings, adds them, and multiplies by a constant* which depends only on the material. For crown-glass the constant is 0·54; and for flint-glass varies from 0·64 to 0·78 according to density. Since I published this, a still more handy device has been brought out by the Geneva Optical Company, of whom Messrs. Botwright and Grey, of Clerkenwell, are agents in this country. It is known as a "Lens-measure," and is depicted in Fig. 13 (p. 36). It is the invention of Mr. Brayton, and consists of a simple form of spherometer with a multiplying-hand to read off the curvature on a dial. But the latter, instead of reading off the mere curvature of the surface, has the readings of its dimensions already multiplied by the proper constant for crown-glass, namely, 0·54; so that the dioptries of a lens are found simply by adding the reading of the two sides.

I will conclude by expressing my satisfaction that the British Association has seen its way to appoint a committee on the subject of the measurement of lenses. With Professor Carey-Foster as chairman, and with Captain Abney, of South Kensington, and Mr. Whipple, of Kew, as members, such a committee ought to be able to effect some real progress in the spread of scientific methods, and so help forward the industry.

* This is equal $\mu - 1$, where μ is the refractive index; or $(1 - h) \div h$, where h is the velocity-constant (relatively to air).

DISCUSSION.

Mr. G. M. WHIPPLE said he had been much gratified at hearing the reference which had been made to the work done at Kew in regard to lenses, for it ought to be better known that an atttempt had been made in this country to create an optical laboratory. He was also very glad to know that the Technical Institute at Finsbury was doing similar work, and he felt sure that with the appliances they had there and the leisure at their disposal—not of Professor Thompson, but of the senior students—many most interesting questions in optics might be dealt with, and he hoped solved, which could not be accomplished by those who had other duties allotted to them. The measurement of lenses for microscopes had not come within the scope of their operations at Kew; their work was the examination of telescopes for the royal navy, binoculars, gun directors, a class of telescope not much known to the general public which had been recently brought out, besides smaller glasses used in the ordinary work of navigation. Again, the sextants which were employed by cadets must bear a certificate, and this had led to increased accuracy in make. There were also certain minor instruments examined, of which he need only mention one, which required a plane surface. The grinding of a plane glass surface was a somewhat difficult operation, and it had not been much required until recently, when they had been introduced and their use rendered compulsory for cadets as artificial horizons in working their sextants. This was a matter of economy to save the waste of mercury, which was somewhat considerable, when mercurial artificial horizons were employed. Plane surfaces of blackened glass were therefore introduced instead. These things had been going on for some time, but of late the Kew Committee had undertaken the examination of photographic lenses, and he must add to the names of the gentlemen who had been mentioned as laying down the lines on which the work should proceed, that of Major Darwin, formerly director of the photographic department of the School of Military Engineering. He had now retired from the Royal Engineers, and had thrown himself thoroughly into this question of testing photographic lenses. He seemed to have consulted all the authorities he could get at, and had made some very ingenious and beautiful pieces of apparatus for the purpose, amongst them being a modification of Grubb's method of determining the focal length of lenses. It was much larger than Professor Thompson's apparatus, being adapted to test lenses of 6 inch diameter and 30 inch focal length, and was about 5 feet long and the same height. It proved very satisfactory in use. He regretted that the word astigmatism had remained on the prospectus and was kept in use, for it undoubtedly was wrong, but still it was a very convenient term to employ, and he did not know what could be substituted for it, and it was apparently understood by users of photographic lenses. There were other terms as regarded distortion and dispersion, which were not altogether correct, and should give place to a more accurate terminology. The point with regard to focal planes, which formed such an important feature in microscopic work, had not come before them in connection with photographic lenses, nor did they use it at all in testing telescopes and binoculars.

Mr. T. R. DALLMEYER said it was very gratifying to find that at last the efforts which were being made to obtain perfection in optical work were to be subjected to critical and scientific examination, which must result in really good work being appreciated. He was particularly interested in what he understood to be a new theory in treating light, as explained in the early part of the paper, and he wished Professor Thompson had developed it further. One of the main things which opticians had to do was, after calculation, to do what he might describe as grinding a lens on paper, and this work, by ordinary processes, was very labourious. He imagined that if the process of which Professor Thompson had only given the brilliant idea, were carried out with regard to the central pencils, that process of going through the mill in lens grinding would be

greatly facilitated. From the one or two hints which had been given, the method seemed to be simplicity itself. There were one or two other methods of obtaining the nodal points besides those which had been mentioned. He should like to ask if, in particular constructions—one of which he was deeply interested in—one o the nodal points was only radially outside the lens, would such an application be suited to the measurement of the lens as regarded its focus. He understood that, for taking long measurements, such an instrument would be hardly applicable, but that it was chiefly confined to the measurement of lenses where the nodal points were either contained in the instrument, or were very close to it.

Mr. CONRAD BECK said he also had been extremely interested in the paper, because he remembered his fearful struggles in endeavouring to work out lenses on the English system, and the delight with which he hailed the Gauss and the German system of reckoning both the signs and the principal planes. Those who had endeavoured practically to work out lenses on the ordinary system, as given in "Parkinson," and such books, would agree with him as to the enormous difficulties there were, which were entirely got rid of when the proper geometrical method of reckoning the signs, and the complete theory of the Gauss points were brought into work. As Mr. Whipple had said, the chief importance of the nodal points was with reference to microscopic work, and in that case there were some very awkward and difficult considerations. In old days, when the achromatic microscope was first introduced, it was understood that some sort of reasonable magnifying scale should be adopted, and an arbitrary scale was taken, in which the inch meant that it magnified a certain amount with a certain tube length. But nobody knew where the tube length was measured from. An American gentleman the other day published a paper in which he tabulated all the various tube lengths as measured by various English and Continental manufacturers, and they varied most enormously. But, even supposing a definite tube length to be taken, the difficulty still remained, because in order to get a magnifying power which should be in any way consistent with changed eyepieces and object-glasses, it was necessary that low power object-glasses should be mounted in enormously long tubes and high powers in very short tubes. When using a low power you then had to have it a loug way from the object to begin with, and that difficulty was increased by mounting it in a tube 3 inch or 4-inch long, which in the case of a 5-inch would be simply preposterous. Then, again, supposing that for the sake of scientific accuracy, such a plan were adopted,—what could be done in the use of a binocular microscope? With the binocular microscope it was essential to have the object glass as near as possible to the binocular prism, whereas if lenses were mounted on the principle suggested, the low powers, which are the very powers used for binocular work, ought to be mounted a long way away from the tube of the microscope. Until, however, this plan was adopted, no really true method of magnification could possibly be established. As a matter of fact opticians at present were making their low-power lenses very much higher in power than they ought to be in order to obtain this standard magnifying power which was adopted as an arbitrary scale. For instance, a modern 4-inch objective was nothing like 4 inches; it was nearer 3 inches, because its nodal point was too far up the microscope. It was put up to a much higher power to produce the same magnifying power in connection with the same eyepiece. This plan got over the difficulty tolerably, but when you changed the eyepiece you began to find that although with one particular eyepiece the magnifying scale was tolerably constant—and could be made absolutely constant—when you changed the eyepiece it did not affect different powers in the proper ratio, and the scale was thrown out. Mr. Whipple said the nodal points were not of so much importance in photographic and other optical lenses, and he was quite right in saying that their position was not of nearly so much importance, but it was extremely important some means should be adopted which eliminated the distances between the nodal points in measuring the focal length of optical instruments.

Professor THOMPSON, in reply, said Zeiss's way of getting over the difficulty about tube length was not quite as Mr. Beck had stated, because Zeiss distinctly attempted to regulate the depth to which the eyepieces were to be plunged down, so that they should not overlap in the same way as in the old arbitrary scale. Whether he was successful in carrying that out with very low powers he could not say. Mr. Whipple seemed to give no hope that the practical user of lenses would be content to change the misleading term astigmatism; but what were you to do if you came across a lens which had two defects, and both were called astigmatism? If they meant different things you must give a different name to one of them, and he thought you ought to give a different name to the thing which was not astigmatism. Mr. Whipple and the Kew authorities ought to invent a name, and then everyone would be obliged to adopt it.

The CHAIRMAN, in proposing a vote of thanks to Professor Thompson, said that this paper constituted a really important contribution to the knowledge of optical measurements. The instrument which had been shown and explained promised to be very useful indeed in the actual examination and specification of lenses. Hitherto there had been no accurate method which was easily applicable for finding the constant on which the action of any lens, and, still more, a combination of lenses, depended. In the ordinary treatment of the

properties of lenses in this country, even in scientific text-books, one got no further than dealing with lenses which were not infinitely thin, but which were dealt with as though they were, and he hoped the paper would have a great effect in widening the ordinary optical discussions, and bringing the ordinary theory more nearly into accord with actual practical experience. As yet they had hardly got beyond Newton's optics. What Gauss introduced long ago, the idea of the virtual thickness of the lens, had scarcely been recognised in all its importance in this country, though it was of the utmost value in facilitating the statement of the properties of lenses. One small point in the paper which he thought of some importance, was the introduction of a term for what he believed had no name before, which was often referred to in foreign writings as the vertex, and which was here called the pole. Professor Thompson had already made important contributions to optical theory; and he would refer especially to some papers of his which appeared two years ago in the *Philosophical Magazine*, where he showed how very simply the properties of lenses could be expressed by the method he had hinted at in the beginning of this paper—by speaking of the curvature they impressed on the wave front of a beam of light passing through them. In those papers he had treated all the ordinary cases from that point of view with extreme simplicity and beauty, and he hoped this method would be adopted generally in the ordinary treatment of optics.

The vote of thanks was carried unanimously, and the meeting adjourned.

Obituary.

GEORGE WALLIS, F.S.A.—Mr. Wallis, who died recently, was a frequent attendant at the meetings of the Society of Arts when subjects connected with art were discussed. He also read several papers before the Society; in 1856 one on "Recent Progress in Design as applied to Manufactures" (*Journal* iv., 291); in 1859 one on "Embroidery by Machinery" (vii., 318); and in 1863 another on "The New Art of Auto-Typography" (xi., 374). Mr. Wallis was born at Wolverhampton in 1811, and, after leaving the grammar school of that town, he settled for a time in Manchester. As early as 1839 he had devoted his attention to the subject which became his life-work, and he delivered his first lecture on "State Aid for Art" in that year. In 1841 he joined the Government School of Design at Somerset-house, and became, in 1843, Head Master of the Spitalfields School. In December of the latter year he was appointed Master of the Manchester School of Design, an office which he held till 1846. He took an active part in the preparations for the Great Exhibitions of 1851 and 1862, for which undertakings he acted as a Deputy Commissioner. For several years he was Head Master of the Birmingham School of Art, a position he resigned in 1858. In 1863 he was appointed Keeper of the Art Collections of the South Kensington Museum, from which office he retired in July of last year.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

DECEMBER 2.—G. H. ROBERTSON, F.C.S., Assoc. Inst. El. Eng., "Secondary Batteries." W. H. PREECE, F.R.S., will preside.

DECEMBER 9.—JAMES DREDGE, "The World's Fair at Chicago, 1893." THE ATTORNEY-GENERAL, M.P., Chairman of Council, will preside.

DECEMBER 16.—GENERAL PITT RIVERS, "Typological Museums, as exemplified by the Pitt Rivers Museum at Oxford."

Papers for which no dates have yet been fixed:—

"Spontaneous Ignition of Coal, and its Prevention." By PROF. VIVIAN B. LEWES.

"Burning Oils for Lighthouses and Lightships." By E. PRICE EDWARDS.

"Dust, and How to Shut it Out." By T. PRIDGIN TEALE.

"Iceland." By T. ANDERSON.

"Artistic Treatment of Jewellery." By I. W. TONKS.

"Agricultural Banks for India." By Sir WILLIAM WEDDERBURN, Bart.

"The Scientific Value of Lovibond's Tintometer." By F. W. EDRIDGE-GREEN, M.D.

"The Agricultural Needs of India." By Dr. J. AUGUSTUS VOELCKER.

"Travels in Indo-China." By LORD LAMINGTON.

"The Woodcuts of Gothic Books." By WILLIAM MORRIS, M.A.

"The Fisheries Department: its Position and Prospects." By J. W. WILLIS BUND.

"The Congo State." By Captain W. LOVETT CAMERON, R.N.

FOREIGN AND COLONIAL SECTION.

The meetings of this Section will take place on the following Tuesday afternoons, at Half-past Four o'clock:—

January 19, February 16, March 15, April 5, 26, May 24.

INDIAN SECTION.

The meetings of this Section will take place

on the following Thursday afternoons, at Half-past Four o'clock:—

January 21, February 11, March 3, 24, April 28, May 19.

APPLIED ART SECTION.

The meetings of this Section will take place on the following Tuesday evenings, at Eight o'clock:—

January 26, February 23, March 8, 29, April 12, May 17.

CANTOR LECTURES.

The following courses of Cantor lectures will be delivered on Monday evenings, at Eight o'clock:—

A. P. LAURIE, M.A., "The Pigments and Vehicles of the Old Masters." Three Lectures.

LECTURE I.—NOVEMBER 30.—A brief account of fresco painting as described by Cennino Cennini, and of the preparation of panels, gesso work and gilding, in the 15th century. Also a description of the preparation of gilt Spanish leather.

LECTURE II.—DECEMBER 7.—The pigments used in the 15th century, and their preparation and properties, with some account of the methods of painting.

LECTURE III.—DECEMBER 14.—The mediums used by the Old Masters, in tempera and oil painting. The preparation of the oils and varnishes, and the properties of the same.

JUVENILE LECTURES.

Two lectures, suitable for a juvenile audience, will be delivered by PROFESSOR JOHN M. THOMSON, Sec. C.S., on the "Three States of Matter: Solid, Liquid, and Gaseous," on Wednesday evenings, January 6 and 13, 1892, at 7 p.m.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, Nov. 30...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. A. P. Laurie, "The Pigments and Vehicles of the Old Masters." (Lecture I.)

British Architects, 9, Conduit-street, W., 8 p.m. Messrs. John Belcher, W. S. Frith, and Thomas Stirling Lee, "Sculpture and Sculptors' Methods in Relation to Architecture."

Actuaries, Staple-inn-hall, Holborn, 7 p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Sir Robert Ball, "Recent Progress in Astronomy."

Royal, Burlington-house, W., 4 p.m. Annual Meeting.

Microscopical, 20, Hanover-square, W., 8 p.m. Conversazione.

TUESDAY, DEC. 1....Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on paper by Mr. H. K. Bamber, "Portland Cement, its Manufacture, Use and Testing." 2. Mr. A. E. Carey, "The Inspection of Portland Cement for Public Works." 3. Mr. William Smith, "The Influence of Sea-water upon Portland Cement Mortar and Concrete."

Pathological, 20, Hanover-square, W., 8½ p.m.

Biblical Archæology, 9, Conduit-street, W., 8 p.m.

Zoological, 3, Hanover-square, W., 8½ p.m. 1. Mr. G. A. Boulenger, "Notes on Transcaspian Reptiles." 2. Miss E. M. Sharp, "Further Descriptions of New Butterflies from British East Africa, collected by Mr. F. J. Jackson during his recent Expedition." (Part II.) 3. Mr. A. D. Michael, "The Association of Gamasids with Ants." 4. Mr. Edward Bartlett, "Notes on the Bornean Rhinoceros."

WEDNESDAY, DEC. 2 ... SOCIETY OF ARTS, John-street, Adelphi, W.C. 8 p.m. Mr. G. H. Robertson, "Secondary Batteries."

Entomological, 11, Chandos-street, W. 7 p.m. 1. Mr. George T. Baker, "Notes on *Lycæna* (recte) *Thecla*, *Rhymnus*, *Tengstræmii*, and *Pretiosa*." 2. Mr. Frederic Merrifield, "The Effects of Artificia Temperature on the Colouring of *Vanessa urticæ* and certain other species of Lepidoptera." 3. Mr. W. Bateson, "The Variation in Colour of the Cocoons of *Eriogaster lanestris* and *Saturnia carpini*."

Archælogical Association, 32 Sackville-street, W. 8 p.m.

Obstetrical, 20, Hanover-square, W. 8 p.m.

THURSDAY, DEC. 3 ... Linnean, Burlington-house, W., 8 p.m. 1. Mr. W. West, "A Contribution to the Freshwater Algæ of the West of Ireland." 2. Dr. W. H. W. Strachan, "The Tick Pest in Jamaica."

Antiquaries, Burlington-house, W., 8½ p.m.

Chemical, Burlington-house, W., 8 p.m. 1. Prof. Thorpe and Mr. A. E. Tutton, "Phosphorus Oxide." (Part II.) 2. Prof. Thorpe and Dr. A. K. Miller, "Frangulin." (Part II.) 3. Messrs. A. Smithels and H. Tingle, "The Structure and Character of Flames." 4. Miss K. J. Williams, "The Composition of Cooked Vegetables." 5. Mr. T. S. Dymond, "The Occurrences of a Mydicatic Alkaloid in Lettuce." 6. Messrs. S. E. Linder and H. Picton, "Some Metallic Hydrosulphides." 7. Mr. Harold Picton, "The Physical Constitution of some Solutions of Insoluble Sulphides." 8. Messrs. H. Picton and S. E. Lindor, "Solution and Pseudo-solution."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. T. G. Pinches, "The Tower of Babel and Confusion of Tongues."

Archæological Institution, Oxford-mansion, Oxford-street, 4 p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m. Mr. A. R. Dresser, "Toning Bromide Paper and Transparencies."

FRIDAY, DEC. 4...Geologist's Association, University College, W.C., 8 p.m. 1. Mr. Arthur Smith Woodward, "Supplementary Observations on Some Fossil Fishes from the English Lower Oolites." 2. Rev. A. Irving, "Organic Matter as a Geological Agent."

Philological, University College, W.C., 8 p.m.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Physical, Science Schools, South Kensington, S.W., 5 p.m. 1. Mr. W. Hibbert, "A Permanent Magnetic Field." 2. Prof. Ayrton, "Note on the Production of Rotatory Currents."

Journal of the Society of Arts.

No. 2,037. Vol. XL.

FRIDAY, DECEMBER 4, 1891.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CANTOR LECTURES.

On Monday evening, 30th ult., Mr. A. P. LAURIE delivered the first lecture of his course on "The Pigments and Vehicles of the Old Masters," in which he illustrated the description of fresco painting by Cennino Cennini, and described the preparation of panels, gesso work and gilding in the 15th century.

The lectures will be printed in the *Journal* during the Christmas recess.

INDIAN SECTION.

A meeting of the Committee of the Section was held on Tuesday, 1st inst., at 4 p.m. Present: Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., LL.D., M.D., in the chair; Lionel Ashburner, C.S.I., Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., M. M. Bhownaggree, C.I.E., Major-General Sir Owen Tudor Burne, K.C.S.I., C.I.E., Sir Theodore Cracroft Hope, K.C.S.I., C.I.E., Lieut.-General J. Michael, C.S.I., Alexander Rogers, Thomas H. Thornton, C.S.I., D.C.L., C. L. Tupper, Sir Alexander Wilson, W. Martin Wood, with Sir Henry Trueman Wood, M.A., Secretary of the Society, and S. Digby, Secretary of the Section.

The programme of papers to be read during the present session was discussed.

APPLIED ART SECTION.

A meeting of the Committee of this Section was held on Wednesday, 2nd inst., at 4 p.m. Present:—Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., LL.D., M.D., in the chair; Prof. A. H. Church, Lord Alfred S. Churchill, C. Purdon Clarke, C.I.E., Francis Cobb, Lewis F. Day, C. M. Kennedy, C.B., A. Lazenby Liberty; Vincent J. Robinson, William Simpson, and Hugh Stannus, with Sir Henry Trueman Wood, Secretary of the Society, and H. B. Wheatley, Secretary of the Section.

The programme of papers to be read during the present Session was discussed.

Chicago Exhibition, 1893.

JURIES AND MEDALS.

The report of Director-General Davis upon the subject of awards and juries has been submitted to a sub-committee, and the substance of the report has been agreed to. The report commences thus:—

"With reference to the precedents furnished by the administrative systems of award at the Vienna Exposition in 1873, at the Centennial in 1876, and at the Paris Exposition in 1889, I have to say at the outset that the Centennial Commission made severe radical departures from the regulations that had previously obtained in foreign exhibitions. The most important of these was the awarding of premiums on the recommendation of individual jurors embodied in signed reports, stating the precise qualities of excellence which justified the award.

"The granting of awards on the vote of a majority of the members of a jury, without precise statements of the motives which prompt the decision, has always been unsatisfactory. Its secrecy and irresponsibility incites the exhibitors to use and judges to yield to unfair, or at least improper, influences."

The Director-General says that if the jury of awards is organised by July 1, 1893, its work can be completed substantially by Aug. 16, and the work of revision finished by Sept. 1. In order to do this, he says it will be necessary to employ a large body of clerks by May 1, 1893, to make preliminary preparations for the juries of awards. The number of jurors required he estimates, after consultation with the chiefs of thirteen departments of the Exposition in which exhibits will be entered, is 659, divided as follows:—

Department of Agriculture—Nine juries and sixty-three judges.

Horticulture—Ten juries, fifty judges.

Live Stock—Fifty-three juries, 159 judges.

Fisheries—Five juries, twenty-five judges.

Mines and Mining—Twelve juries, sixty judges.

Machinery—Six juries, thirty-six judges.

Transportation of Exhibits—Four juries, thirty-two judges.

Manufaatures—Thirteen juries, sixty-five judges.

Electricity—Five juries, thirty-five judges.

Fine Arts—Eight juries, forty judges.

Liberal Arts—Nine juries, seventy-one judges.

Ethnology—Three juries, eighteen judges.

Forestry—Three juries, fifteen judges.

Colonel Davis also recommends that a special jury be drawn from the regular group of juries, to give an award to the exhibit showing the best and most satisfactory installation in each of the thirteen departments. It is also recommended that no juries be organised for the classes comprising agriculture, machinery, and musical instruments, as the representative exhibitors in these classes have declared against awarding medals in those divisions of the departments.

Each of the 500 judges outside of the department of live stock are to be paid six dollars a day for their services, which are not to exceed forty days, and the 159 judges in the live stock department to be paid the same rate, their services being limited to ten days. This payment of six dollars per day is made in lieu of expenses, and not as salary.

Colonel Davis believes that 130,000 dollars will be enough to pay the judges. He recommends that artists of the United States be invited to submit models and drawings for the medals, and that 500 dollars be paid for the best design, and 250 dollars each for the two next best designs. The same prizes he recommends should be given for the diplomas. He recommends further that the policy of the Exposition should be very conservative in respect to the number of awards, and that the authorities should study how they will be able to limit rather than enlarge the number. The special prizes and premiums offered by individuals and associations interested in various classes of exhibits, he believes, should be disposed of in some way, and in accordance with the same rules and regulations governing the medals and awards.

Proceedings of the Society.

THIRD ORDINARY MEETING.

Wednesday, December 2, 1891; WILLIAM HENRY PREECE, F.R.S., Member of the Council of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

De Winton, Major George, Junior United Service Club, S.W., and South Norwood, S.E.
Parker, Thomas, Newbridge, Wolverhampton.
Sandbach, Captain Arthur Edmund, R.E.. A.D.C., care of Messrs. King, King, and Co., Bombay.

The following candidates were balloted for and duly elected members of the Society:—

Adams, Prof. Henry, 60, Queen Victoria-street, E.C.
Allen, James Mason, 11, Gray's-inn-square, W.C.
Allport, William, 36, Southampton-st., Strand, W.C.
Angelo, Elliott, Oriental Club, Hanover-square, W.
Askwith, George Ranken, 119, St. George's-square, S.W.
Barnwell, Richard, Fairfield-works, Govan, near Glasgow.
Basing, Lord, Hoddington-house, Winchfield, Hants.
Beck, William, jun., 3, Glebe-place, Stoke Newington, N.
Bingley, F. S. Norman, M.A., 4, Harrington-gardens, S.W., and Conservative Club, S.W.
Bisset, James, Corsee-house, Banchory, N.B.
Brevetor, Ernest Frederick, Laburnums, Grove-lane, Stamford-hill, N.
Brown, Frederick Gordon, 17, Finsbury-circus, E.C.
Bury, Henry, M.A., 5, Palace Court-mansions, Bayswater, W.
Cane, Arthur, Spring-vale, Bush-hill-park, Enfield.
Cawston, George, Ascot Wood-house, Ascot
Chandler, Frederick L., Lloyd's, Royal Exchange, E.C.
Cheetham, Howard, Carlton-chambers, 18, St. Ann's-street, Manchester.
Child, Gilbert William, M.A., J.P., Cowley-house, Oxford.
Cleeves, Frederick, East-hill, Rotherham, Yorks.
Copland, William Wallace, The Waterworks, Sheerness.
Corthell, E. L., 205, La Salle-street, Chicago, Illinois, U.S.A.
Cruwys, Robert, 465, Brixton-road, S.W.
Cutler, Thomas William, 5, Queen-square, W.C.
Danson, John Towne, Grasmere, Westmoreland.
Dent, Rev. Charles, 76, Westbourne-terrace, W.
Donald, James, 92, Anerley-park, S.E.
Elwes, Henry John, Colesborne, Andoversford, R.S.O., Gloucestershire.
Finnemore, Robert Isaac, J.P., Durban, Natal, South Africa.
Fox, Charles, Roslin, Rectory-road, Beckenham, Kent.
Franklin, Henry Abraham, 14, St. Quintin-avenue, North Kensington, W.
Frost, Robert, B.Sc., 8, King's Bench-walk, E.C., and 42, Duke-street, St. James's, S.W.
Gouraud, Col., Little Menlo, Beulah-hill, S.E.
Graves, Walter, Winchester-house, 50, Old Broad-street, E.C.
Greaves, Joseph Edward Elsworth, Engineering School and School of Science and Art, Rochdale, Lancashire.

Grice, Tom Edmund, Belle-vue, Tonbridge, Kent.
Gripper, George, J.P., Tottenham, Middlesex.
Harris, Walter H., 12, Kensington-gore, S.W.
Hay, John, 11, St. Mary-axe, E.C.
Hill, Frederick Barker, 30, Glengall-road, Peckham, S.E.
Hoblyn, Richard Armstrong, 79, Priory-road, West Hampstead, N.W.
Hogg, Quintin, 5, Cavendish-square, W.
Holt, G. Crompton, Albion-house, Congleton, Cheshire.
Hunter, William, Cathay-house, Eltham, Kent.
Husband, John, Moreton-lodge, Mount Pleasant-lane, Upper Clapton, N.E.
Hutt, Alfred Granger, 8, Oxford-road, Kilburn, N.W.
I'Anson, E. Blakeway, M.A., 7A, Laurence Pountney-hill, E.C.
Irvine, Hugh Alexander, Moray-place, Edinburgh.
James, Alfred, 157, West George-street, Glasgow.
Jones, J. Mortimer, 153, Highbury New-park, N.
Jones, W. Campbell, 32, Bedford-row, W.C.
Kenward, James, 280, Hagley-road, Birmingham.
L'Aker, Major John, Ascot-house, Boscombe, Bournemouth, Hants.
Lamington, Lord, 26, Wilton-crescent, S.W.
Lee, John T., 26, Great James-street, Bedford-row, W.C.
Leeson, Rev. Wilfrid Nevill, B.D., 84, Lancaster-gate, W., and New University Club, S.W.
Low, Alexander G., 38, Pembridge-villas, Bayswater, W.
McCormick, Robert S., 72, Victoria-street, S.W.
McCormick, Rev. W. T., St. Matthew's-vicarage, Brighton.
Macnab, Henry Black, 1, Queen Victoria-street, E.C.
Martin, William, Lambeth Infirmary, Brook-street, S.E.
Meade, General Sir Richard John, K.C.S.I., 65, Queen's-gate, S.W.
Mewburn, George Francis, 10, Elm-park gardens, S.W.
Miles, Colonel Samuel Barrett, The Residency, Oodeypore, Rajputana.
Millson, Alvan, Elmsleigh-house, Paignton, South Devon.
Moore, Alfred, 144, Mile-end-road, E., and Whips Cross, Walthamstow, Essex.
Moore, Commander William Usborne, R.N., 8, Western-parade, Southsea, Hants.

SECONDARY BATTERIES.

By G. H. Robertson, F.C.S., Assoc. Inst. El. Eng.

Introduction.

The secondary, or, as it should rather be called, the reversible battery, dates practically from the discovery that electric currents could be produced by the agency of chemical actions, and its development progressed with the increase of our knowledge of the laws which govern electrolysis.

In the year 1800, Volta discovered that a current could be obtained through chemical agency, and in the following year Gautherot observed that when electrodes of silver or platinum wire were used for the electrolysis of acidulated water, they gave a current in the reverse direction to that in which the battery current had been passing, if they were connected through a galvanometer directly the battery was removed.

These inverse, or polarisation, currents, as they were called, were a source of great perplexity, aud although much work was done on the subject. and many theories were started to account for their origin by Volta, Ritter, Marianini, Becquerel, Grotthus, and others, no satisfactory explanation was forthcoming until Faraday set the whole theory of electrolysis on a firm basis in his papers communicated to the Royal Society between June, 1833, and March, 1834.

Although many apparent contradictions have been found to Faraday's well-known simple laws, and the precise mode in which a current is conveyed through an electrolyte is still under discussion, yet his work showed that chemical and electrical energy were mutually convertible, and that the so-called polarisation currents were due to the reversible nature of the chemical changes caused by the passage of the primary current.

The way was thus cleared for improvements in batteries in general, and very many have been brought out; but it was not till much later, when Faraday's other great discovery of the laws relating to the conversion of mechanical into electrical energy bore fruit, and provided a cheap source of electricity, that much attention was paid to reversible batteries.

In the course of his experiments on electrolysis, he nearly anticipated Planté's discovery of the peroxide of lead—lead couple, for in the case of the electrolysis of a solution of acetate of lead, he noticed that on the passage of the current, peroxide of lead was formed on the one plate and lead on the other.

In 1843, Grove invented his gas battery; and in 1852, Dr. C. W. Siemens constructed a reversible battery, using carbon plates as his electrodes, and a strong solution of acetate of lead as his electrolyte.

In 1859, Planté made a number of experiments with copper, silver, tin, lead, aluminium, iron, zinc, gold, and platinum voltameters, to determine which was the best couple to use for a reversible battery, and decided on the use of lead plates in dilute sulphuric acid, because in discharge both plates were active, that is, not only did the peroxide of lead plate combine with hydrogen, but the reduced metallic lead combined with oxygen; thus the E.M.F. of the cell was due to chemical actions occurring on both plates. In those days the action of the cell was ascribed solely to the decomposition of water, and the effect of the sulphuric acid was left out of account.

In 1872, Planté improved the "formation" of his cell by bringing out the process for alternate reversals of the current, and in the decade which followed, with the improvement of the dynamo, and the consequent growth of electrical engineering, the need for some means of storing electrical energy arose, and the reversible battery passed from the laboratory into commercial use.

Reversible Batteries.

In 1880, M. Camille Faure invented his cell, in which the electrodes consisted of lead plates, smeared with pastes of red lead and litharge respectively, and covered with a protecting layer of felt. On charging, the red lead was oxidised to peroxide of lead, and the litharge was reduced to metallic lead, thus quickly forming a Planté couple of considerable storage capacity.

The same impetus in electrical work which gave rise to the Faure battery, led also to the introduction of several other types of reversible batteries, and as I have been able to obtain very little information about them, I will deal with them and their developments now, before proceeding with the numerous improvements in the two lead types.

Professors Thomson and Houston have tried electrodes of copper in sulphate of zinc solu-

tion; the plates were laid horizontally, so that the relative weights of the sulphate of zinc and sulphate of copper formed in the working might prevent their mixing too readily. The E.M.F. was the same as that of the Daniel.

M. d'Arsonval modified this battery by making one electrode of lead and the other of zinc, the solution being sulphate of zinc as before. The lead plate forms the positive, and becomes coated with peroxide during charge. According to Miesler, the E.M.F. of this arrangement is 2·13 volt.

Sutton tried copper and lead plates in copper sulphate, the E.M.F. being 1·22 volt.

In 1886, M. Dezmazures brought out a modification of the Lalande and Chaperon cell, the solid copper plate being replaced by a porous one, made by first reducing copper oxide electrically. and then compressing the fine metallic dust so obtained into plates.* The other electrode was made of tinned iron gauze, and the solution was potassium zincate. The E.M.F. is only about 1 volt, but the cells are light, and a battery of this description gave satisfaction, as a source of motive power, at the trials on the French torpedo-boat *La Gymnote*, at Toulon. Recently this battery has been tried for traction work in Philadelphia, under the name of the Waddell-Entz accumulator.† In the American form of the battery, the copper plates are made of a sort of wire rope, formed of a stout wire core, braided over in opposite directions with two layers of wire of different thicknesses, the finest outside. This is again braided with asbestos, or some similar material, which retains and protects the copper oxide formed by electrolysis. The weight of the battery is given as from 55 to 60 lbs. per h.p. stored.

Lead Reversible Batteries.

On the introduction of the Faure cell into England, in 1881, great hopes were entertained of it, and the modification in the manufacture of the plates seems almost to have been regarded as constituting a fresh type of cell, whereas, since the couple was identical, the chemical reactions were the same as in the Planté cell, and any defect due to these would be common to both. As lead reversible batteries cannot be said to have completely realised the hopes then entertained, it is important to discover whether the non-fulfilment is due to causes which can be remedied by improved processes of manufacture, or whether they arise from the chemical reactions occurring in the working of the cell, and are to be met rather by improved treatment after, than during construction. I have thought, therefore, that a paper containing a summary of some of the principal improvements which have been introduced in the construction of the cells, and an account of some experiments dealing with the chemistry of the subject, might lead to some usefel discussion.

From a comparison of the two cells, made by M. Achard, it appears that on its introduction the internal resistance of the Faure was much higher than that of the former, while the Planté cell took longer to form, and was heavier than the Faure.

The time required for formation, and the weight of the cell, were the chief drawbacks to the Planté process of manufacture; the Faure method had the disadvantage that the applied paste was liable to separate from its support. The remedying of these defects, then, has been the principal aim of the improvements which have been brought out in the two types of the lead reversible battery.* To give a complete list of these would be quite beyond the scope of this paper, but they may be summarised as follows:—

I.—Improvements in the Plante Type.

By the Planté type is meant that in which the peroxide of lead and spongy lead are formed direct from metallic lead by electrolysis.

In this type, since both the weight of the plate and the time required for "formation" can be shortened by making the plate porous, and thus exposing more surface to the action of the acid and charging current, obtaining porosity has been the chief aim of inventors. The methods which have been suggested from time to time may be classified under three headings:—

A. *Chemical.*—The plates are subjected to some "pickling" process, or some special "forming" bath is used.

B. *Mechanical.*—The plates are made of

* For an account of the lead batteries on their first introduction into commercial work, and of the early suggestions to replace them, see a paper by Prof. W. Grylls Adams, F.R.S., read before the Science Society of King's College, 25th October, 1881, and published in *The Chemical News*, vol. xlv., p. 1. In Mr. Niblett's paper on "Some Recent Improvements in Lead Secondary Batteries," read before the Physical Society of Glasgow University last January, and published in *The Electrical Engineer*, vol. vii., Nos. 13 to 17, will be found an account of the principal structural improvements which have since been effected.

granulated lead, wire, or some form of finely divided lead.

C. *Electrolytic.*—(1) The finely divided lead is obtained by the electrolysis of some salt of lead; (2) Some salt of lead is formed into a plate by pressure or otherwise, and then reduced to metallic lead.

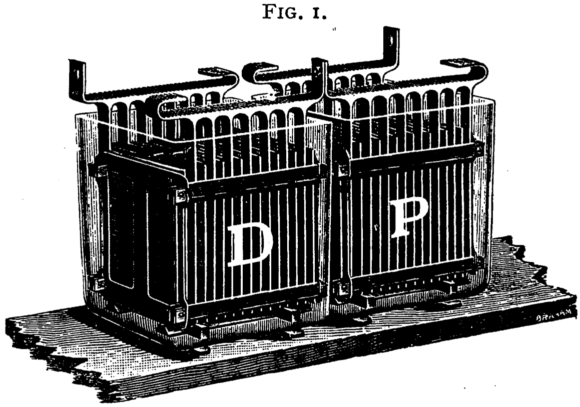
Chemical Processes.—Planté found that plates of lead which had been steeped for a long time in dilute sulphuric acid, before being submitted to the action of the charging current, "formed" more rapidly than those which had not been so treated, and he also found that "formation" was hastened by heating the cell during the process; this, however, was difficult in practice.

In 1882, in order to roughen the surface, he pickled the plates, for from twenty-four to twenty-eight hours, in a bath composed of nitric acid diluted with from once to twice its volume of water. The plates were then thoroughly washed, and the formation completed in a bath of dilute sulphuric acid one to ten. By this improvement he stated that a capacity, which under the old process took several months to obtain, could be acquired in eight days.

Almost simultaneously, Messrs. Elwell and Parker suggested the use of a mixture of nitric and sulphuric acids as a pickling bath. Since then different baths, containing nitric acid in varying proportions, have been brought out, and from the earliest times the addition of some salt of the alkalies, such as ammonium, sodium, potassium, or magnesium, sulphate to the electrolyte during formation, has been suggested as an improvement.

In 1884, Mr. FitzGerald proposed the use of phosphoric acid; and in the same year Mr. Tribe experimented with plates partially or

FIG. 1.



MESSRS. DRAKE AND GORHAM'S CELL.

wholly converted into sulphide, phosphide, or arsenide, prior to "forming" them by electrolysis.

Coming to recent processes, in 1890 Mr. Epstein suggested first boiling the electrodes in a bath containing

1 per cent. nitric acid;
1 „ „ potassium permanganate;

or else, in lieu of the permanganate, two per cent. carbonate or sulphate of sodium, or one per cent. sulphate of manganese. The plates are dried in air, and then "formed" by the action of the current in an electrolyte containing acetic, phosphoric, or tartaric acid, in the proportion of one-half to two per cent.

A few months later, Dr. Paul Schoop brought out his process for first subjecting the plates to the action of a current of about one-sixth of an ampère per 100 sq. c.m., at 50 degees Fahrenheit, in a bath composed either of—

100 parts by weight ammonium sulphate;
140 „ „ „ sulphuric acid (50 degs.);
⅔rds 1 pt. „ „ potassium chlorate:

or else—

100 parts by weight water;
5 „ „ „ sodium bisulphate;
⅔rds 1 pt. „ „ potassium chlorate.

The treatment is continued for from thirty-six to 100 hours, according to the depth of the active material required. The formation is completed in ordinary dilute sulphuric acid.

Mechanical Processes.—Messrs. Crompton and Howell's well known plates, formed by the compression of a specially porous granulated lead, are an instance of this type, and from their great porosity, they are capable of a very high rate of discharge.

In Messrs. Drake and Gorham's cell (Fig. 1), the plates are formed of roughened

strips of lead, laid horizontally one over the other, and connected by their ends to upright rods. From its construction this plate is free to expand and contract without injury to itself.

In Mr. Niblett's so-called "solid cell," * the electrodes are separated by porous partitions, and the space between the electrodes and the partitions is filled up with granulated lead. In this cell there is practically no free electrolyte to wash about and spill; it is all absorbed either in the mass of spongy material forming the electrodes, or in the porous partitions.

Plates have also been made of compressed lead dust, of wire loosely woven and compressed, as in Reynier's cell; or in the form of rope, as in the Legay cell.

M. Bandsept's plates would appear to be of this type, as they are made of extremely finely pulverised material, which is then compressed into briquettes, and subjected to a forming process. The cell is now in use commercially in Brussels, but very little information can be obtained about it.

ELECTROLYTIC PROCESSES.

1. *The electrolysis of some lead salt solution.*—The acetate of lead has been frequently employed for this purpose since Siemens used it; and another salt that has been the subject of many patents is the chloride of lead. In America last year it was proposed by an Englishman, named Currie, to form the electrodes of rods or bars of lead coated with woven asbestos. These electrodes are then placed as anodes in a bath of zinc chloride, and lead chloride to the required depth is formed on them, while zinc is deposited on the cathodes. On reversing the current, spongy metallic lead is produced on what are now the cathodes, and the zinc goes into solution, being thus used over and over again.

2. *The reduction of a plate formed of some salt of lead.*—Perhaps more patents have been taken out under this heading than any other. Plates have been formed of the fused chloride; cerussite, or the native carbonate, has been compressed into plates, and in fact any salt of lead, even lead sulphate, which can be got to reduce to metallic lead by the action of the current, has been employed.

In the Laurent-Cely cell the plates are composed of pastilles of specially prepared lead chloride, round which frames of an alloy of lead and antimony are cast. By the action of zinc in very dilute hydrochloric acid, the plates are converted into cellular lead. The plates are then washed in cold water, dried, and the positives converted into litharge by the action of a current of hot air. The formation is then completed by electrolysis in the usual way.

For this cell it is claimed that the density of the positives is 4·3 to 5, while that of the negatives is only 3 to 3·5. Great storage capacity for weight is also claimed.

* *The Electrical Engineer*, vol. viii., No. 4, p. 80.

II.—IMPROVEMENTS IN THE FAURE TYPE.

By the Faure Type is meant that in which the peroxide of lead and spongy lead are formed by electrolysis from some oxide applied to the plates.

As in this class of cell the active material is applied to the electrodes, and not formed from them as in the original Planté cell, it is obviously desirable that the supporting part of the electrode should be light, and not weakened by taking part in the chemical reactions. These requirements have been met in many instances by replacing the solid lead plate by a grid, usually made of an alloy of lead and antimony, since such an alloy is less acted on by the acid, and is much stronger than pure lead. In the E.P.S. cell the use of an alloy of lead and antimony was abandoned, because, if sufficient antimony to obtain a good casting was added, the grid was so hard that it did not yield to the expansion of the paste, which consequently forced itself out of the plate. Lead grids were then employed, but now they have been abandoned for rapid discharge work, and a solid plate has been reverted to.

In the latest form of Mr. FitzGerald's lithanode cell, weight is reduced by making the support of a light double frame of copper wire, protected from the action of the acid by dipping it first in soldering fluid, and then in molten lead.

The other improvements fall into two principal divisions:—

A. Those which have for their object the retention of the paste on the plate, and they may be classed under four headings.

B. Those intended to provide better connection between the support and the active material.

A.—The Retention of the Paste.—1. The plate is not perforated, but grooves or recesses are made on the surface; or it is cast with projections from it, so as to afford a lodgement for the active material.

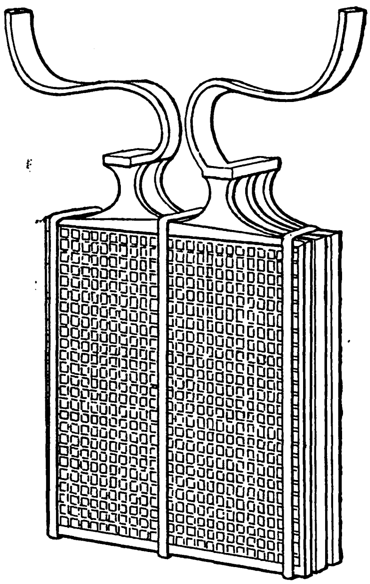
The Tudor plate is a familiar instance of this type, which has the advantage that the support gradually gets "formed," and supplies

active material to replace that lost in the working of the cell.

In the new 1890 pattern E.P.S. plate, an early form, introduced originally by Swan, has been resorted to. The plate is grooved horizontally, as in the Tudor plate, and the ridges between the grooves curve slightly upwards towards the surface of the plate, forming a lodgement for the paste.

2. The support is some form of "grid," that is, is perforated with holes, as in the old pattern E.P.S. plate, and the Julien grid (Fig. 2).

FIG. 2.



ELEMENT CONSOLIDATED EL. STORAGE CO.

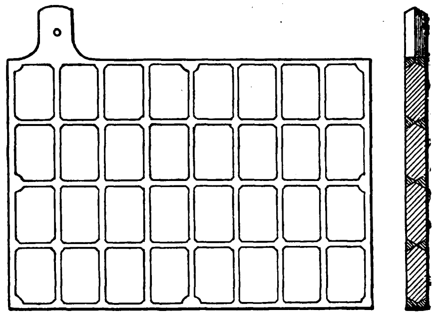
A great many varieties of this form of plate have been suggested, and the apertures have been made by casting the grid in a mould, and by punching. Their form has been cylindrical, barrel shaped as in Messrs. Drake and Gorham's positive plates, shaped like two cones joined at the apexes, and to give greater security the perforation has been made to expand again just at the junction of the apexes.

The construction of a mould, to produce a perforation expanding inwardly, is a matter of difficulty, and therefore the grids are sometimes cast in two halves, and subsequently joined, as in the Gadot cell (Fig. 3). In the Correns cell, (Fig. 4), much used in Germany, the grid takes the form of a double lattice.

3. The active material is enclosed in a perforated conducting retaining vessel.

In this case also the devices resorted to have been very numerous. Plain or corrugated sheets of lead have been taken and folded into boxes, either before or after applying the paste.

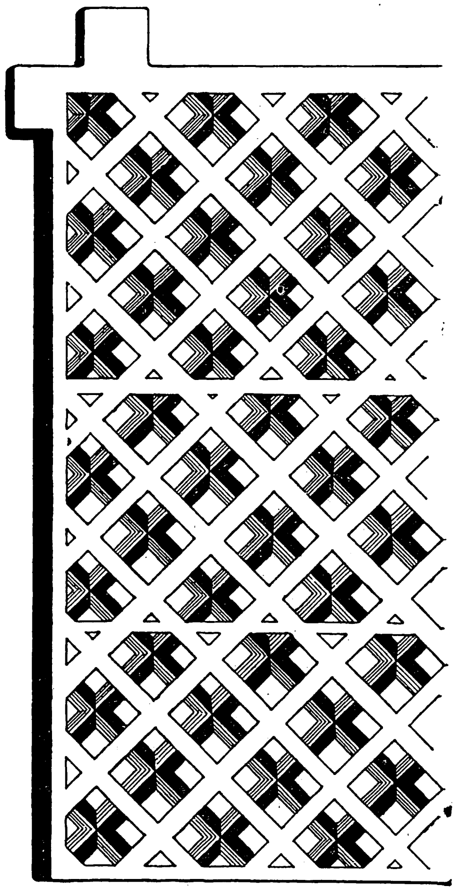
FIG. 3.



PLAN AND SECTION GADOT PLATE.

In the Roberts cell (Fig. 5, p. 49) two grids are taken, pasted on one side, and then united to form a plate with the paste inside (Fig. 6, p. 49).

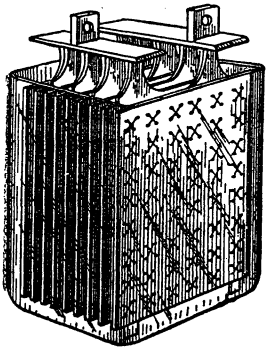
FIG. 4.



PLAN OF CORRENS DOUBLE GRID.

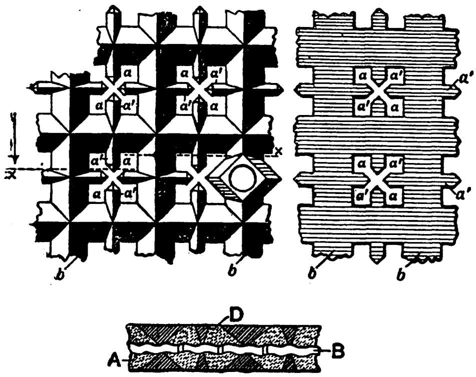
In Dr. Tommassi's multitubular cell (Fig. 7, p. 49) the retaining vessel may be constructed o

Fig. 5.



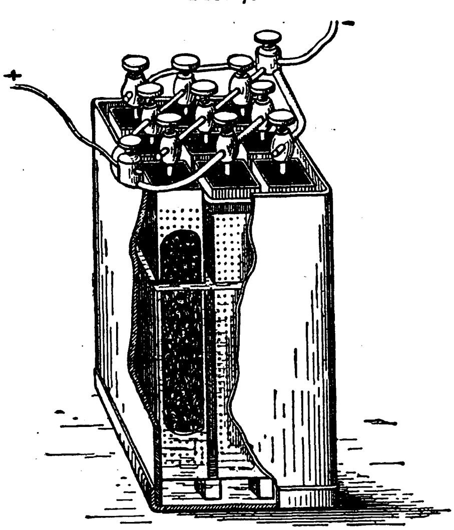
"Roberts" Cell, Complete.

Fig. 6.



"Roberts" Cell: Detail of Plate.

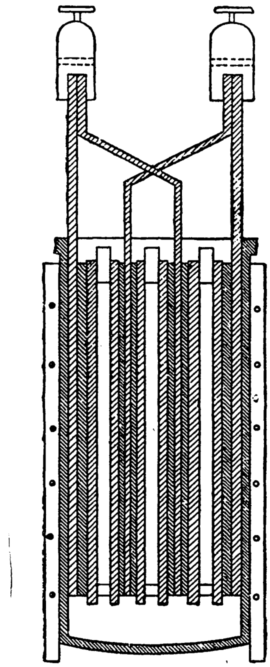
Fig. 7.



Tomassi Cell, Corner Cut away to Show Internal Arrangement.

metal, but is usually of some non-conducting material, and so comes under the next heading.

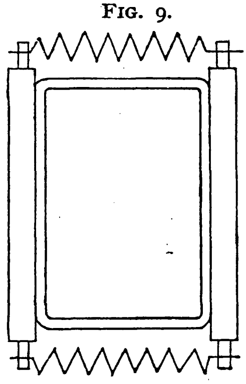
Fig. 8.



Reynier Element: Side View.

4. The enclosing vessel or plates are made of some non-conducting material, or some inactive material is packed between the plates,

Fig. 9.



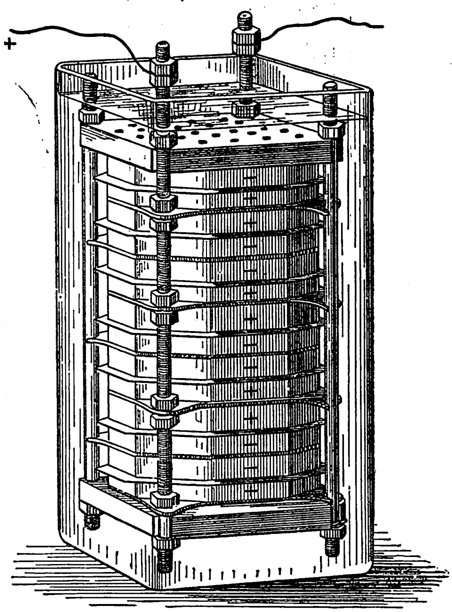
Reynier Element: Plan of Compressing Arrangement.

to prevent short-circuiting, and retain the active material.*

* The improvements under this heading are equally applicable to cells of the Planté type; but as they are more frequently applied to cells of the Faure type, I refer to them under this heading.

In France, the plates have been covered with perforated sheets of celluloid; Reynier brought out what he called an "elastic cell," specially designed for use on torpedo boats. When tried in 1886, on board *La Gymnote*, it was not a success, and the alkaline copper cell was preferred to it. Since then, however, the construction has been much improved (Fig. 8, p. 49). Each cell, according to improvements effected in 1889, is composed of one positive, two negative plates, and four porous partitions held together, as shown by a frame consisting of two end plates connected together by corrugated strips of metal, which have sufficient elasticity to enable them to expand and contract with the alteration in volume of the plates caused by charge and discharge (Fig. 9, p. 49).

FIG. 10.



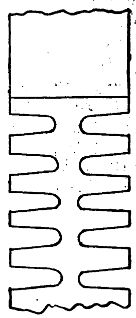
"ATLAS" CELL.

In this country Mr. Barber Starkey has tried filling in between the plates with a mixture of plaster of Paris and sawdust; Mr. Fuller uses porous pots; and in the United States, in the Pumpelly battery, cellulose, or wood pulp, is used to separate the plates, which are arranged horizontally, as in the "Atlas" cell (Fig. 10).

B.—Improved Connection between the Applied Oxide and the Support.—With this object the support has been well rubbed with carbon before applying the paste, and the addition of carbon to the paste in some form has been frequently recommended, as, for instance, kneading the oxides into a paste with lead acetate.

In the Tudor cell (Fig. 11) the positive plates are first treated by Planté's process, to coat them with a layer of crystalline electrolytic

FIG. 11.

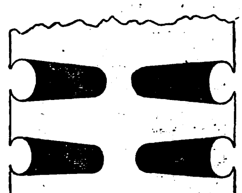


TUDOR PLATE: SIDE VIEW, EMPTY.

peroxide; the grooves are then partially filled with a paste of peroxide of lead, and pressure is applied to the ridges to expand them, and partially close the mouths of the grooves (Fig. 12).

The casting or welding of the applied oxide to the plate has also been tried, and, to overcome the difficulty of getting the substances to blend into one another, caused by the great difference in their melting point, it has been suggested to fill the portion of the mould usually occupied by the support with some reducing agent, such as carbon mixed with nitre, so that when the fused oxides are poured into the mould they will be reduced in part to metallic lead, which will assume the place and shape of the carbon core, while the remainder forms the active material.

FIG. 12.



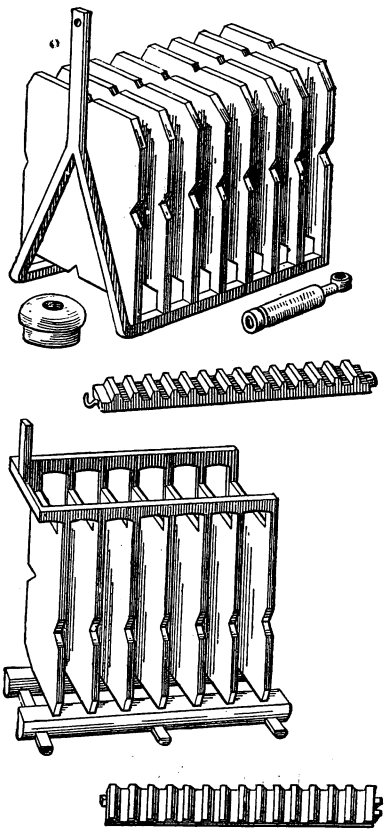
TUDOR PLATE: SIDE VIEW, FULL.

General Improvements.—Besides the improvements in what may be called the manufacture of the plates, or electrodes proper, various devices have been resorted to with the view of diminishing the resistance of the lugs,

and securing better contact between plates of the same sign, such as making connection by tinned copper rods passed through holes in the lugs. Lead is afterwards cast round the copper, so that it is screened from the action of the acid.

Some attention has also been given to the question of the best electrolyte to use, some advocating the use of acid of density 1,150 to 1,180, while others recommend a density 1,200 and over. The addition of small quantities of some salt of the alkalies, such as sodium sulphate or carbonate, has been recommended

FIG. 13.



PLATES OF "OERLIKON" CELL SEPARATED.

by Mr. Barber Starkey and others, with a view of reducing sulphating; and Dr. Paul Schoop has brought out a successful gelatinous electrolyte, by adding one volume of dilute sodium silicate, density 1·180, to two volumes of dilute sulphuric acid, 1·250.

In order to prevent shortcircuiting between the plates by the material dislodged in working, they are now either slung, or rest on supports, which are so placed that the formation of a layer of mud between them is prevented.

The equalisation of the chemical action over the surface of the plates has also been attempted, and in the Schoop cell (Fig. 13) the current enters at the top of one set of plates, and leaves from the bottom of the others. The plates also are widely spaced now as a rule, the proportion of acid to plates has been increased, and little alterations are constantly being made to secure the free circulation of the electrolyte essential to regular working.

THE CHEMISTRY OF THE ACID.

Although so many different modes of manufacture and preliminary treatment have been resorted to, all the batteries, so far as I am aware, which depend for their action on the couple formed between lead and lead peroxide in dilute sulphuric acid, exhibit the characteristic peculiarities noticed by Planté in his cell, namely:—The high initial E.M.F. of a freshly-charged cell; the fall of E.M.F. on breaking the charging circuit, with corresponding rise on breaking the discharging circuit; the very rapid fall towards the end of discharge which occurs earlier, the more rapid the discharge is, and is not due to the exhaustion of the active material, as after a rest a fresh discharge can be obtained.

As the defects, namely, sulphating and buckling, which have retarded the introduction of reversible lead batteries, are also common to the two types, it appeared possible that they were due to the same causes which produced the variations in E.M.F.; therefore, as the work of Dr. Oliver Lodge* in 1883, and of Miesler† in 1888, had shown that the causes of the variation must be sought either on the lead plate, or in the acid next it, and the chemistry of the plates afforded no explanation,‡ I last year, with Dr. Armstrong's advice and assistance, undertook the investigations of the reactions occurring in the acid.

Planté § had considered that the peculiarities in E.M.F. were due to the formation of peroxides in the acid, and showed that the conditions existing in a cell were favourable to their production, since in voltameters with lead electrodes they were formed in greater quantity than in those with platinum. He also noticed that, immediately on the cessation of the charging current, there was often a small evolution of gas from the peroxide plate; this evolution

he ascribed to local action between the peroxide and the subjacent lead.

Commenting on this, in their little book, "The Chemistry of Secondary Batteries," Messrs. Gladstone and Tribe point out that the gas is oxygen, and cannot be due to local action, since the gas was evolved whether the peroxide was removed from the supporting plate or not. The application of heat increased the evolution of gas, and the gas was oxygen. Testing the acid between the plates, they always found traces of something which decolourised permanganate, and might, therefore, be hydrogen dioxide or ozone.

Although a very large amount of work has been done on the electrolysis of sulphuric acid solutions, and the general character of the change in the nature of the products formed as the strength of the solution is varied, is well understood, the only references I was able to find to any examination of the acid in a battery were those just given; and therefore I have ventured to bring the results of my own experiments before this Society, not because I consider them a final solution of the difficult problem of the chemistry of the cell, but because I hope that the study of the changes occurring in the electrolyte may help to elucidate some points which are at present obscure.

And now it may be as well to refer briefly to the work which has been done in sulphuric acid.

In 1878 Berthelot* discovered persulphuric acid ($H_2S_2O_8$), and brought forward evidence to prove that it is the primary product of the electrolysis of sulphuric acid solutions, and that the hydrogen dioxide—which, from Faraday's time, has been well known to be present in sulphuric acid after electrolysis—is really due to the action of this body on the acid. The products of electrolysis vary with the strength of the acid, 40 per cent. acid (density 1300) yielding practically no hydrogen dioxide; while below and above that strength it is present in varying proportions. High-current density, and an electro-negative condition of the electrodes favours their formation.† Persulphuric acid is an unstable body, and begins to decompose as soon as the current which has given rise to it is stopped, and its decomposition is accompanied by the formation of hydrogen dioxide, unless the sulphuric acid is too dilute. Hydrogen dioxide is also unstable when concentrated, but a weak sulphuric acid solution of it is comparatively stable, and the stability increases the less hydrogen dioxide it contains, therefore this body is found in estimable quantities long after the persulphuric acid which gave rise to it has disappeared. Persulphuric acid is at once decomposed by spongy metal, such as platinum-black, by heat with evolution of oxygen,* and resembles hydrogen dioxide in these reactions, and in releasing iodine from potassium iodide, but, unlike it, has no action on permanganate of potassium or peroxide of lead. The effect of electrolysing a sulphuric acid solution of hydrogen dioxide is simply to increase the rate of the decomposition occurring spontaneously, if a weak E.M.F. is used;† but on increasing the E.M.F., though the rate of decomposition is increased, a little persulphuric acid is re-formed. Subsequent workers have in the main confirmed Berthelot's conclusions. To the oxidising oxygen in the products of the electrolysis of sulphuric acid, Berthelot gave the name of "active oxygen," and as they pass one into the other, and for most purposes connected with a battery it is not necessary to discriminate between them, I have retained it.

Experiments at the General Post Office.

That the nature of the electrolyte affected the behaviour of the cell, was evident from information received from Mr. Barber Starkey with respect to the effect of the addition of sodium carbonate; and it seemed possible that the different behaviour of cells containing this substance was due to its catalytic action on hydrogen dioxide, which is known to be exceedingly unstable in the presence of a trace of alkali; and hence a comparative study of the reactions occurring in cells containing ordinary dilute sulphuric acid, and in those which had been treated on Mr. Barber-Starkey's plan, seemed likely to elucidate the causes of the sulphating during rest, and the high initial E.M.F.—the two features most affected by his treatment.

Mr. Preece most kindly aided the investigation by allowing experiments to be carried out at the General Post Office, where one half of the secondary cells contain 1 per cent. of sodium sulphate, and the other half ordinary dilute acid, density 1180. He also put at my disposal the records of the behaviour of the cells, and they proved that there was much

* Berthelot. (*Compt. Rend.* 90, 269-275.)
† Richarz. (*Ann. Phys. Chem.* [2] 31, 912).

† Berthelot. (*Compt. Rend.*, 95, 8-11).

less sulphating with sodium sulphate, as shown by the density of the acid never falling to the same extent as in the plain cells. The following readings taken from short circuited cells with badly broken plates illustrate this. In two cells containing ordinary dilute acid the density of the electrolyte had fallen to 1100, while, according to the last readings before the short circuit occurred, it had been 1170, and 1180 respectively; while in two sodium sulphate cells the density had only fallen to 1180 from 1200 under similar circumstances.

This was strong evidence in favour of the hydrogen dioxide formed in the working of the cell being appreciable in quantity, since if sulphating were only due to local action between the support and the paste, there does not appear any reason why the addition of sodium sulphate should affect it.

Whenever the cells were tested they were always found to contain "active oxygen," which was due to the presence of persulphuric acid and peroxide of hydrogen in varying proportions. During charge persulphuric acid is the main constituent; during discharge the quantity of hydrogen dioxide gradually increases; while in a cell which has been at rest sometime there is very little except hydrogen dioxide to be found.

In addition to the tests made on the cells in the electric light and telegraph batteries, I studied the formation of the "active oxygen" during charge and discharge on some cells which were kindly set apart for my special use. The "active oxygen" forms at once on the passage of the current, decreases slightly, and then increases to a little above its first value. Starting either charge or discharge always causes an initial increase, except in the case of cells which have been long idle, when there is a diminution due to the decomposition of the excess of hydrogen dioxide in the acid.

To test whether electrolysed acid was able to reduce pure peroxide of lead, two equal lots of peroxide were taken by weighing one against the other, and put in two flasks. On to each, 100 c.c. of acid, from next the positive plate of a cell at full charge was poured, and this caused the evolution of oxygen, which continued slowly for some days. At the end of a fortnight the amount of peroxide of lead in each sample was estimated, and it was found to have decreased from 97·4 per cent. to 93·94 and 94·04 per cent. respectively.

This appears to explain the well-known deleterious effect of rest on a cell, for although persulphuric acid itself does not reduce peroxide of lead, it forms hydrogen dioxide on standing, which is capable either of oxidising the lead plate to litharge, or of reducing the peroxide plate to the same substance. In each case the litharge is converted into sulphate by the sulphuric acid.

In an ordinary cell in good order the amount of "active oxygen" is small, varying in quantity from about 0·01 grm. to 0·02 grm. per litre; but this means that in a forty-five pint cell (the size used at the Post Office) there was always sufficient to convert from 3·25 grms. to 7·5 grms. of peroxide of lead into sulphate, or to undo the work of one to two ampère-hours charge.

This is not a serious matter if the cells are kept working, as the peroxides are being continually broken up with each reversal of the current, but if the cells stand idle the plates get sulphated, and the amount of "active oxygen" formed in the next passage of the current shows a marked increase.

The figures just given do not represent the total amount of "active oxygen," since the acid absorbed by the plates cannot be tested; but as the acid has more oxidising power the nearer you get to whichever is the positive plate, except at the commencement of discharge, and the total quantity of "active oxygen" increases rapidly soon after breaking circuit, it seems fair to assume that this increase is due to diffusion from the plates of acid which has more oxidising power than that in the body of the cell.

This increase is followed by a decrease which is rapid at first, and then gradually gets very slow, and practically ceases while there is still a fair proportion of "active oxygen" left in the cell.

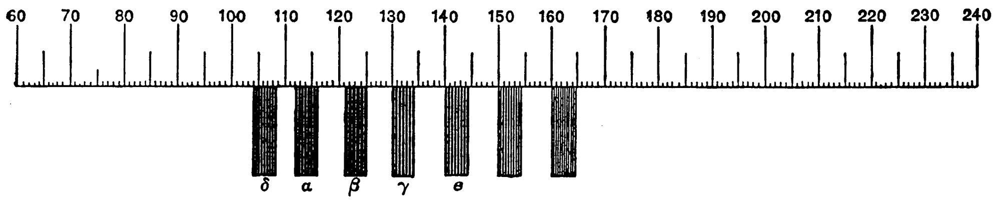
In the sodium sulphate cells the amount of the oxidising agent was usually less than in the plain cells; and the amount of hydrogen dioxide was always so, unless the battery had been at rest for some time, when the conditions were occasionally found to be reversed. This, I suppose, is due to the proportion of "active oxygen" in the form of hydrogen dioxide, at the moment of stopping the current, being greater in the plain than in the sodium sulphate cells, while the latter contain more persulphuric acid. In both cells the hydrogen dioxide present at the time of stopping the current will be reduced on the plates, sulphating the surface, and more or less screening them from further action; but as the sodium sulphate cell contains more persulphuric acid,

the subsequent formation of hydrogen dioxide will be greater in it than in the plain cell. As far as I could discover, sodium sulphate has little or no action on the acid unless it is added during electrolysis, or to acid which has just been taken from a cell through which a current is passing.

The Pink Colour of the Acid.—It has often been noticed, that during charge, particularly with new cells, a pink colour starts from the peroxide plates, and gradually spreads over towards the lead plates, fading away however before reaching them. This pink colour was referred to by Mr. Crompton at a meeting of the Institute of Electrical Engineers on 13th December, 1890, and its origin gave rise to some discussion; so as the acid in many of the cells at the Post Office was pink, I tested it by concentrating it down, neutralising with sodium carbonate, and then igniting on platinum foil, and always got the characteristic green of manganese.

However, lest the manganese should have come from some other source than the pink acid, I compared the absorption spectrum of the acid with that of a solution of potassium permanganate of the same shade of pink, and found they both gave the characteristic bands in the green (Fig. 14). I also found that, using two strips of platinum as electrodes in a solution

Fig. 14.



Absorption Spectrum of Potassium Permanganate.

of manganous sulphate, or any two strips of lead in dilute acid, gave the same colour and the same absorption bands, provided the electrodes were sufficiently far apart to prevent reduction by the hydrogen evolved from the negative. This result was important, for it is well known that the pink colour disappears from the acid in a short time if it is taken from the cell, and as persulphuric acid has no action on permanganate, but hydrogen dioxide decolourises it, this disappearance of the colour shows that the latter is formed.

The Effect of Hydrogen Dioxide on the E.M.F. of a Cell.—The presence of hydrogen dioxide having been thus proved, both directly and indirectly, its effect on the E.M.F. of the cell was tested. This was done by using strips of lead packed tight into small porous pots, with peroxide of lead to represent the peroxide plates, and using plain strips as the lead plates. A solution of pure sulphuric acid, density 1180, was used as the electrolyte. The E.M.F. of the couple was taken by the deflection method, and then a drop or two of hydrogen dioxide was added to the acid, which produced a great diminution, or even reversal, of the E.M.F.

The effect of introducing hydrogen dioxide into the body of the peroxide paste was also tried, with a view of reproducing, if possible, the conditions of a cell, which is started discharging directly the charge is completed, and in which the "active oxygen" would be accumulated at the positive plate, leaving the lead plate free, and I found that there was a slight increase in E.M.F.

Thus the variations in E.M.F. appear to depend on which plate hydrogen dioxide is formed at. When present at the peroxide plate it causes a rise, but when diffused through the acid and present at the lead plate it causes a lowering of the E.M.F.; and the rise in E.M.F., sometimes noticed on starting the discharge of a cell which has been at rest (mentioned in Professor Ayrton's paper, J.I.E.E., 1890, p. 572), is probably due to the electrolysis and decomposition of hydrogen dioxide, for, in a cell which has been long idle, practically the whole of the "active oxygen" is due to this body.

Conclusions.

From the same faults appearing in batteries of such different construction, and judging also from the results of the experiments recorded in this paper, it would appear that the troubles occurring in batteries are due rather to causes arising in the working than in the manufacture. What is required is some substance which can be added to the acid to check the formation of

the oxidised bodies in it, which cause sulphating, without at the same time injuring the plates in other ways.

Nearly all the "forming" baths which have een introduced are baths in which hydrogen dioxide would be broken up as soon as formed, and, perhaps, in some modification of them the electrolyte of the future will be found; though, since the products of the electrolysis of sulphuric acid vary with the strength of the acid and the current density, no hard and fast rule can be laid down for the treatment of cells.

In cells containing acid below density 1200, in which the proportion of "active oxygen" existing as hydrogen dioxide is high, the addition of one per cent. of sodium sulphate, or similar substance, is likely to prove beneficial, particularly if the work of the cells is intermittent. As the strength of the acid is increased, however, and the conditions are more favourable to the stability of persulphuric acid, less hydrogen dioxide will be produced, and there is more chance of the alkali released from the sodium sulphate during electrolysis damaging the plates.

Also, Dr. Marshall has succeeded in preparing pure persulphuric acid, and has shown this year that it forms salts with the alkalies which are very stable; and what the effect on a cell of the formation of sodium persulphate in it would be, is quite unknown. Although the formation of peroxides in the acid does not apparently account for the great gassing and sudden loss of charge sometimes observed, still we have seen that makers are reverting to Planté's process of manufacture, or modifications of it, and we may find that in this case also he was right, and that it is to the electrolyte we must look if we wish to find the means of materially improving the lead reversible battery.

In conclusion, I must thank the firms who have assisted me in the compilation of this paper by supplying information in response to circulars sent out. This information has also been used in table of types given on pp. 52-53.

DISCUSSION.

Mr. JAMES SWINBURNE said this was a very important paper, but he would not waste time in mere compliments upon its merits. Though Faure was credited with being the first to use the cells which bore his name, he would remind those interested that Kirchoff, an American, used a secondary battery of the same sort, with platinum plates, in which he electrolysed nitrate of lead and got a coating on both plates. He was not quite at one with Mr. Robertson as to the means used in "forming." He tried a number of experiments on this subject in 1883, but in all cases a solution was employed, which would first dissolve the lead and then precipitate it; in fact the idea was to follow the action in the manufacture of white lead. If you took a plain lead plate and eat into it with dilute sulphuric acid, it got coated with peroxide, which protected it. Planté kept reversing the action. This uncovered a new portion of the lead, and so by degrees eat into the body of the plate. He had tried nitric, sulphuric, and acetic acids, various chlorides, and a large number of other solutions; but the great trouble with nitric and other solutions was that traces of material were left in the cell which would eventually eat through the plate and destroy it. The least trace of chloride was fatal; it acted as a sort of carrier, and whenever it was used you failed to get a coherent coating. He got the best results with acetic and sulphuric acids in certain proportions. Acetate of lead was first formed; and as soon as the sulphuric acid got at it, it converted it into peroxide. He thought the idea of heating the plates was due to Brush, who published a very elaborate patent on the subject—a regular treatise—and, amongst other things, he mentioned heat to reduce carbonic oxide; and also that he got a very coherent spongy lead by the use of an alkaline solution. Such solutions did not give lead trees, but a closely adherent sponge. He also tried Dr. Schoop's silica jelly, but was not successful with it. It was very good at first, but soon changed, and was a jelly no longer. He examined some Schoop cells at the Frankfort Exhibition, which looked very like ordinary cells. There was no jelly in them, but there were several clots which, he was told, probably arose from something having fallen in. He also experimented with carbon; but the classical experiments with this substance were made by two Italians, whose names he forgot; and they found that carbon could never be used in any electrolyte from which oxygen was given off. It might be used in a strong solution of chloride, but, even then, it would waste away. He had not gone into the chemistry of it, but he knew that, in time, the carbon turned into a sort of black mud, which had no consistence whatever. He was the first, he believed, to recommend strong acid, and the reason was this: the action of a solution was due to the affinity of the radicle of the acid for the lead; if you had a dilute solution, the acid wanted of course to form a solution, and there was a certain heat formation; but if you used a strong solution you got a lighter E.M.F., because the acid had no longer the same inclination to mix with water, and therefore the inclination to form the lead salt was the stronger. He tried how far this could be carried, and at a certain point he found the spongy lead began to decompose the solution very quickly, and gave off bubbles of hydrogen, and that seemed to be the limiting point. Various theories had been started with regard to the pink solution; Mr. Crompton said it was due to gold;

others said, if so, that was the first instance in which gold had come from a secondary battery. He found he could make the pink solution artificially by leaving peroxide of lead in commercial sulphuric acid, but in pure sulphuric acid it did not occur. The strength of the solution was also of importance; with very strong acid he got a much deeper colour. On testing it he found no trace of manganese, but a good deal of iron. At the same time Mr. Robertson was a skilled analyst, and on that point he was probably right.

Mr. Robertson said he had tried the corresponding iron salt, and found no absorption bands at all.

Mr. Swinburne said he only regretted that Mr. Robertson had not given more information about copper and other cells; people had been working at lead a great many years, and he believed the tendency now was to turn to copper as the cell of the future.

Mr. M. Immisch said he was a considerable user of accumulators, and judging from the number of people who came to him with ideas, there must be something very fascinating in the subject. No end of people came to him with designs, some patented and some not; sometimes with actual apparatus, sometimes wholly imaginary; and his invariable answer was—Send me at your earliest convenience a dozen of your cells at your own price, and if only half what you promise is fulfilled, I can promise you every success. As this had been going on for some years, and though he had given dozens of orders, he had not yet got the cells; the inference was obvious. He himself had fallen under the spell, for, some three years ago, it occurred to him that the amount of active material in the cell was very small in proportion to the total weight, and he thought he would try to remedy that. He procured some solid peroxide plates, and at first the results were marvellous, but in a short time they were not so good, and ultimately he found they would not stand at all. The cells now made were very satisfactory in one way, if they were not so heavy, and if only manufacturers would give them more output in proportion to the weight they would do all that was required. In his experiments he found that the outside contact was at first very good, but it soon deteriorated, and at length there was none at all; so that he came to the conclusion that there was something more intimate, more solid, wanted between the conductor and the active material than he could get.

Mr. Bernard Drake said the D.P. cells were of the Planté type, but they had obtained not only the durability of that type, but the capacity which was supposed to belong only to those of the pasty type. The cells he first issued contained much greater capacity than any they had ever been able to make for the Electric Storage Company: he tested them carefully, and the capacity was very high, but they very soon deteriorated. On trying to produce them on a commercial scale, they met with a number of difficulties, and found that the rusting action which took place in the oxidizing of the plates was very difficult to restrain or to equalise throughout the battery; but by a number of processes since introduced they had overcome this difficulty, and could now form plates by the thousand with a very small percentage of failures. The plates had been in use two years, and with properly-made cells they found no deterioration. It showed how history repeated itself, that after many years' experimenting with pasty plates they found it better to return to the old Planté cells. The rate of discharge was also very satisfactory; the conductor was simply a laminated strip, of a very early type, separated by the thin layers of peroxide formed on their surface, and the current could therefore be taken equally all through the plate, instead of taking it off at one corner, as was the case with peroxide plates alone, or plates of porous material. In the course of his experiments he had entirely confirmed the statement of Mr. Gorham in his paper at the British Association, that the great enemy was sulphate in excess, which produced buckling. If you could stop excessive sulphating there would be no buckling; but if batteries were allowed to run out, and were left under conditions which would produce excessive sulphating, nothing would save them. This was common to all lead batteries, however made or treated. With regard to the specific gravity of the acid, his experience was that it should be varied according to the work required. For lighting a country house, where the cells would be left a fortnight or longer without changing, the specific gravity should be lower, and the voltage lower also, but the capacity of the cell should be greater. With such cells the risk of sulphating would be less. On the other hand, if the cells were to be used, as some had been at a large central station, discharged at about three times the ordinary rate allowed for plates of such a size, then the peroxide was liable to be reduced to the consistency of mud; under such conditions, better results were obtained with a higher strength of acid. With regard to copper cells, he had a good deal to do with Messrs. Elwood and Parker at the time the copper cells were brought over, and the return in proportion to the weight was certainly greater than from lead, but the invariable difficulty was that the zinc appeared to be soluble in the solution, and unless the discharge was taken pretty soon after the charge, the cell ran itself completely out in a single night. So far he believed no one had been able to get over that difficulty, otherwise there would be a great future for copper cells.

Prof. H. E. Armstrong, F.R.S., said this paper marked a distinct epoch in the history of these reversible batteries, as Mr. Robertson very properly called them; the term, secondary battery, threw a sort of halo of mystery round the matter, which had dis-

tinctly retarded progress. This paper would serve to call attention to the great importance of studying the chemical changes going on in these cells, for up to now the matter had been almost entirely in the hands of electricians, and the chemical side had been to a great extent overlooked. The only thing noted was the interaction between sulphuric acid, the lead, and the peroxide. It was true that certain peroxides of hydrogen, and so on, were produced in minute quantity in the cell, but these were not taken much account of, whereas the outcome of the paper seemed to be that these substances which had been so neglected were really the disturbing agents, and that if the work of these cells was to go on with greater certainty and regularity under varying conditions, it would only be by making such alterations in the electrolyte, or otherwise, as would get rid of these perturbing elements. It was not a question of ordinary chemistry; this persulphuric acid to which attention had been called was a substance which the ordinary student of chemistry would probably have no knowledge of; and therefore the very highest chemical skill must be used if these problems were to be satisfactorily solved. During the last few years he had been more than once consulted as to recommending a chemist to those who were engaged in working at these cells, but on making inquiries he found as a rule that the pay offered was such as an ordinary laboratory office-boy would scarcely accept. The idea was that someone was required who would make an occasional analysis of the peroxide, lead, sulphuric acid, or other materials employed; and it was the prevalence of that sort of notion which was answerable for so little progress being made. No chemist had set himself to the problem who had been able to thoroughly master the conditions, and study the question from all sides. If they had set to work in this country, when the cell was first introduced, as the Germans were doing now, the battery would years ago have been in a far better condition than it was now. From the chemist's point of view, he was much inclined to sympathise with what Mr. Immisch said; for if 5 per cent. of the weight of the cell was of any direct use, that was the very utmost, and it did seem strange, therefore, that it could not be very much lightened. It was also interesting to see how they were going back to the Planté form. Mr. Robertson and he had long been of opinion, from a theoretical point of view, that that was the right form, and that the pasty form was necessarily imperfect. The main reason for making the cell so heavy was a mechanical one; it was difficult to secure snfficient strength to prevent the plate from buckling unless such dimensions were employed.

Mr. Desmond Fitzgerald, after complimenting Mr. Robertson on his paper, said he thought no essay on this subject was complete unless some reference was made to the fact that every form of the lead secondary battery was an essentially defective apparatus in one electro-chemical respect—that in fact a great blunder, though probably an inevitable one, was made in their construction, and that blunder was the bringing into contact with each other an electrolyte in two substances, so far apart in the electrical chemical scale as peroxide of lead—almost the most electrically negative element they knew—and lead, which was not far off zinc amongst positives. This at once suggested the question how was it, when all the elements for the production of a voltaic current of great intensity were provided, that the lead support which was in contact with the peroxide was not immediately oxidised and consumed. A partial answer had been given by Dr. Gladstone and Mr. Tribe, and a partial answer also by Messrs. Drake and Gorham. One phenomenon observed, whenever a piece of ordinary lead was brought into contact with the peroxide, was that the sulphating of the solid lead was merely superficial; and this protective superficial coating of sulphate of lead was the princpal reason why this blunder, as he called it, was not attended with more destructive effects. Another cause was, that when you charged a lead support containing an active material which was convertible into peroxide of lead, the support was coated with an impervious layer of peroxide. If you charged a plate carefully, and set it by for some weeks, its capacity remained almost unaltered; but if it were partly discharged, and the peroxide layer were broken, the deterioration of the lead support was very rapid. He had an idea of his own as to the construction of a secondary couple, which would be free from the defect he had pointed out, but it was too late to enter into it, and he would therefore defer a description of the lithanode to some other occasion.

Mr. Shippey wished to say that the Tommasi cell was not the invention of Dr. Tommasi, but of Dr. Woodward, an Englishman living in Toronto. He took it to Paris to show a certain firm, and Dr. Tommasi, not knowing it was patented in France, copied it, and it was now known to the world by his name. He had already stated the facts in the *Electrician* and in the *Electrical Review*. With regard to the cell, No. 3, that was his traction cell, called in Paris the "Atlas." He made a double peroxide plate for the purpose of giving a very light cell, and they were now being made on a large scale, giving 200 ampere hours, and the current could be taken off as required. Cells for lighting and for traction purposes ought to be constructed quite differently. His idea of a cell was a cylindrical one, such as was now being constructed at Messrs. Golding's works. Dr. Woodward had arrived in London, and they would shortly be able to show a cell to the Society of Arts of from 3,000 to 4,000 ampere hours; they were from 6 ft. to 8 ft. high for large central station work, and 3 ft. or 4 ft. diameter, perforated so that the acid through the entire plate and short circuiting was almost impossible. He regretted

that he had not been able to send Mr. Robertson particulars of these cells, but the patents were then pending, and he could not do so, but he should now be happy to give Mr. Robertson any information he required. There were two cells, a combination of the Gibson and the Woodward, which he honestly believed would do all that was required for traction purposes. The weight of the cylindrical cell would be about 35 per cent. less than the E.P.S. The negative plate was formed of lead, which was poured when melted over salt; then the salt was dissolved out, and then it was filled with a combination of various chemicals which he could not mention at present, which did not in any way affect it. The peroxide plate was of the Faure type, so arranged that it could not fall out; and he believed it would not buckle. The lead formed by the salt process was pure spongy lead, which could be cut into strips of any size required.

Mr. W. H. Patchell said he believed the Collins grid was the one seized by the German Government, and turned out of the Frankfort Exhibition, as it was thought to be an infringement of the General Post Office patent, but it was really Mr. Sellon's grid, and was now used for the negative in the General Post-office, but not the discharging plate. The Tudor plates were really horizontal, both positive and negative. In the General Post-office the positive plate was practically the same as the Tudor, but in the negative it was really the No. 4 grid, which gave a perfect negative as far as he knew at present. As mentioned by Mr. King last winter, the negative plates, when some eighteen months or two years old, began to show signs of shrinking, and with the ordinary form of square pellets they would fall away, but with the lattice grid the more it shrank the tighter it became. Dr. Oliver Lodge had pointed out that there were three ways in which a cell could break down; it could fail from a defect in the positive, the negative, or the electrolyte; and he held Dr. Schoop's would break down from the latter. Any jelly or sawdust, or anything which prevented the diffusion of the electrolyte would eventually break down the cell, because the strong acid concentrated on the plate and corroded it.

Mr. Robertson, in reply, said he had taken the Fauré cell as the type of lead-pasted batteries, because the date of the introduction of this cell marked an epoch in the manufacture of reversible batteries. In the Kirchoff cell, the plates were platinum, and therefore it was not altogether representative of lead cells. He had used improvements simply in the Patent-office meaning, and must not be understood as recommending any particular make. He had failed to get any more information about copper cells than he had given. Diminution of weight was of course the great point, and he hoped when they knew more about what happened in a on leaving it to stand at rest, the persulphuric acid would break up, probably, and form hydro-dioxide. With dilute acid, roughly speaking, two-thirds of the acid was hydrogen-dioxide, which was undoing the work you were doing in charging; and the same thing applied in discharging; you increased the rate at which the cell would run down. Increasing the strength of the acid, increased the total quantity of active hydrogen formed, but the proportion of hydrogen dioxide in it decreased. Since the paper was written, he had had an opportunity of making expericell, they would be able to construct them better; at present they were working a good deal in the dark. A very small portion of the weight was active material, and the difficulty had always been that you must have so much more material than you could use. Mr. Drake had confirmed his view that the strength of acid should depend on the work to be done. For a high rate of discharge, he believed in a high specific gravity, because, in working, you did not get such a large proportion of hydrogen dioxide formed, though ments on some of Mr. Crompton's cells, which confirmed the views put forward in the paper from theoretical considerations. The density of the acid in the cells tested, when fully charged, was about 1240, and they contained, practically, no hydrogen dioxide. The difficulty mentioned by Mr. Fitzgerald had been felt for some time, but it was mainly a question of cost. He wished him every success with his lithonode cells. He was obliged to Dr. Armstrong for his appreciative criticism, and to Mr. Shippey for the information he had given.

The Chairman then proposed a vote of thanks to Mr. Robertson. He had had opportunities of watching the care, zeal, and determination with which the author had attacked the question, for, coming as he did with a strong recommendation from Professor Armstrong, he had great pleasure in placing at his disposal all the resources of the Post-office. For years past they had been the most earnest advocates of reversible batteries for various purposes. They had used them for electric lighting, and were now using them to a great extent for the telegraphs. The whole system of telegraphy between this country and the Continent, including the telephone to Paris, was worked by these batteries, and he hoped gradually they would drive out of the field altogether the primary batteries. At present, however, they still had 30,000 of these, so that there was a big field for this very useful apparatus. Before many years were over, he felt sure that these 30,000 batteries would be reduced to one-tenth of the number, by the aid of secondary batteries, and with great economy. Mr. Robertson had not dealt with one very important point, viz., the chemico-mechanical cause of buckling, which was one of the great troubles which chemists ought to attack. He had, however, cleared up many difficult points, and they had certainly learned that whatever was produced by one man as his invention

was immediately claimed by some one else. That showed how able men all over the world were directing their attention to this matter, and endeavouring to solve the mysteries of this instrument, which promised to revolutionize the practical application of electricity. Another point which might have been referred to was the practical use of sodium, of which he might give an instance. In May last it was reported to him that there were twenty-eight 13 E.P.S.L. cells terribly sulphated, all covered with hard sulphate, and various attempts to get them into working order were made without success. Then a saturated solution of carbonate of soda was added, about half a pint to each cell, and at once the whole difficulty disappeared—the battery was got into order and had worked successfully ever since.

The vote of thanks was carried unanimously, and the meeting adjourned.

[Mr. Robertson exhibited some fine crystals of persulphate of ammonium and potassium, prepared by Dr. Marshall in the Chemical Laboratory of Edinburgh University.]

Miscellaneous.

UNIFORM MUSICAL PITCH.

Information has been received from Colonel K. Levi Fuller, secretary of the committee appointed by the Piano Manufacturers' Association of New York, to inquire into the subject of uniform musical pitch in the United States, that the committee have reported to the Association, and recommend the adoption of the French pitch, or *diapason normal* (A 435). The meeting held to consider this report on November 6th unanimously agreed to adopt the recommendation, and this pitch will henceforth be the standard for the United States. It was stated at the meeting that the pitch in general use in New York is A 452, but that this occasionally rises to A 460. Throughout the country it is estimated that as many as 100 different pitches are in use. President Wheelock was authorised to adopt a device to be stamped on all the new forks, which will, in future, be known as the "International pitch;" and it was decided that all instruments sent out by the members of the Association after July 1, 1892, shall conform to that pitch. The New York Committee have collected tuning forks representing the pitch in use at the present time; these have been rated at the Massachusetts Institute of Technology, Boston, by Prof. Charles R. Cross. Prof. Charles R. Cross and W. T. Miller, of Boston, prepared a paper showing the condition of musical pitch in Boston and vicinity. Since the issuing of the committee's circular, October 10th, 1891, twenty-six additional forks have received their preliminary rating, and are yet subject to correction by Prof. Cross. Colonel Fuller further announces that the Massachusetts Institute of Technology have ordered a new tonometer, and Prof. Cross desires to compare all forks thus far rated by the very latest apparatus.

It will be remembered that in 1886 the Council of the Society of Arts announced the abandonment of the Society of Arts pitch in favour of the French *diapason normal.*

SCIENCE AND ART DEPARTMENT.

The Lords of the Committee of Her Majesty's Most Honourable Privy Council on Education have issued the following minute on examinations affected by the Technical Instruction Act, 1889. The minute is dated 12th November, 1891, and signed by Major-General Donnelly:—

"1. My Lords consider the subject of the examinations of the Science and Art Department in Science in relation to the funds applicable to Science and Art and Technical Instruction placed at the disposal of county councils and county boroughs under the Local Taxation (Customs and Excise) Act, 1890, and in relation to the operation of the Technical Instruction Act, 1889.

"2. It appears that the number of candidates presenting themselves for examination in science is already so large—about 190,000 papers in various branches of science were worked at the examination in May last, besides above 14,000 practical examinations—that the machiney of examination and registration is already severely strained. These numbers will, in all probability, soon be so increased as to render it impossible to make satisfactory arrangements for the examination of the candidates at the local centres, or for the examination of the worked papers under any system of central examination.

"3. At the same time, the means recently placed at the disposal of local authorities for providing or aiding instruction seem to render it unnecessary for the Science and Art Department to continue to give direct aid for very elementary instruction in science. Such instruction can now be more effectually organised and maintained locally. It is very desirable that the payments for imparting it should, to some extent at least, not be made on the results of individual examinations. Local authorities, with their local knowledge, and knowledge of local needs and requirements, are in a position to make capitation grants or payments for general efficiency in a manner which a central authority, whose rules must be the same for all parts of the country, cannot adopt; and my Lords feel assured that they may count on having the support and assistance of these bodies in forwarding the arrangements for placing instruction in science—the necessary foundation for any sound technical education—on a satisfactory footing.

"Under these circumstances, my Lords have decided that, after the May examinations of 1892, the payments of £1 now made for the second class in the elementary stage of each science subject shall cease.* An elementary paper will continue to be set in each subject, but the results will be recorded simply as *pass* or *fail*, the standard for passing being about the same as that now required for a first-class, *i.e.*, about 60 per cent. of the marks obtainable.

"5. At the same time, with a view to encourage more advanced instruction, which does not seem to be adequately provided for at present, the payments for the advanced stage and for honours will be considerably increased. The payments on results will be then £2 for a pass in the elementary stage; £5 and £2 10s. for a first or second class respectively in the advanced stage; and £8 and £4 for a first or second class respectively in honours, in each subject of science, and in each sub-division of subject 6, theoretical mechanics, or of subjects 8, sound, heat, and light, with the following exceptions:—the payments for practical chemistry will be £3 for a pass in the elementary stage, and £6 and £3 10s. respectively for a first or second class in the advanced stage: the mathematics will be £2 for a pass in stage 1, £3 and £2 respectively for a first or second class in stages 2 and 4, £4 and £3 for a first and second class respectively in stage 3, £5 and £4 for a first or second class respectively in stages 5, 6, and 7, and £8 and £4 respectively for a first or second class in honours. The payment for Section 1 (geometrical drawing) of subject 1 will remain as at present, 10s.

"6. The payment for attendance in an organised science school will be increased to £1 in the day school and 10s. in the night school.

"7. As it is of great importance to prevent large numbers of wholly unqualified candidates being presented at the examinations, the examiners will be instructed to note the papers of all such as would not obtain above 25 per cent. of the marks, and a deduction will be made from the grant to each school for each such paper sufficient to cover the cost incidental to its examination.

"8. The committee of a science school in a place in Great Britain with less than 5,000 inhabitants which does not receive aid from the local authority, or of any science school in Ireland, will be allowed to continue until further notice on the present system, if they so desire it."

* The payments on the results of the examinations in 1892 will not be effected by this minute.

NOTES AND HINTS ON THE VEGETABLE PRODUCTS OF TROPICAL AFRICA.

By John R. Jackson.

At a time when the products of the soil in tropical Africa are very much in the minds of men, and when companies and individuals are specially interested in developing those resources, the following hints on the nature of the principal vegetable products found in tropical Africa as indicating to the explorer or collector what to look for, and their values when found, will probably be useful.

Two things should be borne in mind, namely, the discovery of new products and the development of those already known, and a knowledge of the botanical affinities of such as are already trade products, will materially help the collector in his search for new sources, whether in the matter of oil seeds, drugs, fibres, or what not. In the following notes the products are classified under their respective commercial heads, and the whole must be looked upon as hints, rather than as an exhaustive list.

India Rubber or Caoutchouc.

The various kinds of African rubber at present known to commerce are furnished by climbing plants belonging to two natural orders, namely, Apocynaceæ and Urticaceæ; the bulk of them, however, are from the first-named order, and from plants belonging to the genus *Landolphia*, of which the following species have been described:—1. *Landolphia owariensis*, extending from Sierra Leone, Angola, the Niger, and the mouth of the Congo, where it is known as the "Mvoochi;" it is the "Abo" of the Niger. 2. *L. florida*, widely distributed over the whole of central tropical Africa, yields a portion of the rubber both from the east and west coasts; native name, "Mbungu." The globular acid fruits are edible, and are known as "Aboli." 3. *L. Kirkii*, an East African species, found on the Zanzibar coast. 4. *L. Petersiana*, also a native of the east coast.

Liberian Rubber.

(*Ficus*, or *Urostigma Vogelii.*) The trees yielding this rubber are known in West Africa by the name of "Abba." The rubber has been valued in the London market at 1s. 6d. per pound, but would realise higher prices if sent home in a cleaner state than it hitherto has been. The District Commissioner at Badagry, writing in 1888, says, "From the trees already in full growth in the bush and towns a considerable export trade could be rapidly established, and systematic planting would develop the trade to almost an unlimited extent."

Any plants belonging to the orders Apocynaceæ, Euphorbiaceæ, or Urticaceæ, may be examined for the presence of rubber, for it is from plants of these three orders that all the rubber of commerce is obtained. The finest Para rubber is furnished by an euphorbiaceous tree, *Hevea brasilienois*, and the Assam and Central American rubbers from urticaceous plants *Ficus elastica* and *Castillia elastica* respectively.

Gutta-percha.

True gutta-percha is obtained from *Dichopsis Gutta*, a sapotaceous tree of Singapore, Penang, Borneo, &c.; the nearest approach to it as an

African product is gutta shea, obtained from the "Shea," "Galam," or "Bambouk" butter-tree (*Butyrospermum Parkii*), a tree 30 or 40 feet high. Shea butter is the solid fat contained in the seeds. It is useful for making hard soaps. Gutta shea is separated from the fat in the course of soap-making, and is found to be present to the extent of from ·5 to ·75 per cent. Though somewhat similar to gutta-percha, it has not yet come into use. A kind of gutta-percha is also obtained from the trunk of the tree in small quantities.

Plants or trees belonging to this order—Sapotaceæ—should be examined for the milky juices of their trunks, and the seeds for the fats or oils they contain. Sapotaceous seeds may be recognised by their shining brown hard skins and broad dull scar, which usually extends the whole length of the seed.

[To be continued.]

General Notes.

St. Petersburg Exhibition of Life-Saving Appliances.—It is announced in the *Board of Trade Journal* that an Exhibition of appliances for the prevention, detection, and extermination of fires, and of life-saving apparatus, will be held at that capital in April, 1892, and that further particulars can be seen, if desired, on personal application to the Commercial Department of the Foreign-office.

Chicago Exhibition.—The Berlin correspondent of the *Standard* gives the following quotation from the *Reichszanzeiger* :—" The question of Germany's participation in the International Exhibition at Chicago is now viewed by German employers of labour with different eyes. Up to a short time ago, the representatives of many branches of industry most deeply concerned in the American trade persisted in an unfavourable attitude, but now the conviction that abstention would cause great injury to German industry, and that it is a duty of honour to take care that German industry be worthily represented, is becoming general."

Italian Industrial Museum.—The *Regio Museo Industriale Italiano* was founded at Turin, in 1862, when that city was still the capital of Italy; and when the seat of Government was removed to Rome, it was, although a national establishment, continued at Turin. It has grown into a large institution, in which instruction in industrial engineering, chemistry, physics, mechanics, &c., in all the higher branches of technical education is carried out. One of the departments is a Commercial Museum, in connection with which is an office for collecting information from Italian Consular agents, transmitted through the Italian Foreign-office at Rome. The collections of raw products, and the manufactures produced from them, occupy 45 rooms, and the Educational Department, which contains an assortment of objects from all civilised countries, especially British and Italian, occupies ten rooms. The collections have been largely added to by contributions from British donors. The Museum publishes an *Annuario*, the last issued being for the scholastic year 1890-91.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

December 9.—James Dredge, "The Columbian Exposition at Chicago, 1893." The Attorney-General, M.P., Chairman of Council, will preside

December 16.—General Pitt Rivers, "Typological Museums, as exemplified by the Pitt Rivers Museum at Oxford." Professor Flower, C.B., Director of the Natural History Museum, will preside.

Papers for meetings after Christmas :—

"Spontaneous Ignition of Coal, and its Prevention." By Prof. Vivian B. Lewes.

"Burning Oils for Lighthouses and Lightships." By E. Price Edwards.

"Dust, and How to Shut it Out." By T. Pridgin Teale.

"Iceland." By T. Anderson.

"Ancient and Modern Art Pottery of Japan." By Ernest Hart.

"Artistic Treatment of Jewellery : The Jewel and Address Caskets." By I. William Tonks.

"Agricultural Banks for India." By Sir William Wedderburn, Bart.

"The Scientific Value of Lovibond's Tintometer." By F. W. Edridge-Green, M.D.

"The Agricultural Needs of India." By Dr. J. Augustus Voelcker.

"Travels in Indo-China." By Lord Lamington.

"The Woodcuts of Gothic Books." By William Morris, M.A.

"The Fisheries Department : its Position and Prospects." By J. W. Willis Bund.

"The Congo State." By Captain W. Lovett Cameron, R.N., C.B.

Foreign and Colonial Section.

The meetings of this Section will take place on the following Tuesday afternoons, at Half-past Four o'clock :—

January 19, February 16, March 15, April 5, 26, May 24.

Indian Section.

The meetings of this Section will take place on the following Thursday afternoons, at Half-past Four o'clock :—

January 21, February 11, March 3, 24, April 28, May 19.

APPLIED ART SECTION.

The meetings of this Section will take place on the following Tuesday evenings, at Eight o'clock:—

January 26, February 23, March 8, 29, April 12, May 17.

CANTOR LECTURES.

The following courses of Cantor lectures will be delivered on Monday evenings, at Eight o'clock:—

A. P. LAURIE, M.A., "The Pigments and Vehicles of the Old Masters." Three Lectures.

LECTURE II.—DECEMBER 7.—The pigments used in the 15th century, and their preparation and properties, with some account of the methods of painting.

LECTURE III.—DECEMBER 14.—The mediums used by the Old Masters, in tempera and oil painting. The preparation of the oils and varnishes, and the properties of the same.

JUVENILE LECTURES.

Two lectures, suitable for a juvenile audience, will be delivered by PROFESSOR JOHN M. THOMSON, Sec. C.S., on the "Three States of Matter: Solid, Liquid, and Gaseous," on Wednesday evenings, January 6 and 13, 1892, at 7 p.m.

HOWARD LECTURES.

A Special Course of Six Lectures, under the Howard Bequest, will be delivered on the following Friday evenings, at Eight o'clock, by PROF. W. CAWTHORNE UNWIN, F.R.S., "The Development and Transmission of Power from Central Stations."

February 5, 12, 19, 26, March 4, 11.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DEC. 7.....SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. A. P. Laurie, "The Pigments and Vehicles of the Old Masters." (Lecture II.)

Farmer's Club, Salisbury Square Hotel, Fleet-street, E.C., 6 p.m. Paper on "The Working of the Local Government Act, 1888," by the Chairman.

Royal Institution, Albermarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Westminster Town Hall, 7½ p.m. Mr. G. M. Lawford, "The Drainage of Town Houses."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Mr. Watson Smith, "A Contribution to our knowledge of the Soluble and and Resinoid Constituents of Bituminous Coals." 2. Dr. Murray Thompson, "The Salt Industry of India."

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. C. H. Bedells, "Party and Party-Fence Walls."

Geographical, Uuiversity of London, Burlington-gardens, W., 8½ p.m. Mr. D. G. Hogarth, "Passes of the Taurus and Anti-Taurus."

Medical, 11. Chandos-street, W., 8½ p.m.

Victoria Institution, 1a, Adelphi-terrace, W.C., 8 p.m. Paper by Rev. W. St. Clair Tisdall.

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Edmund Gosse, "Ibsen and his Critics."

TUESDAY, DEC. 8 ..Farmer's Club, Salisbury Square Hotel, Fleet-street, E.C., 5½ p.m. Annual General Meeting.

Medicul and Chirurgical, 20, Hanover-square. W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Henry Gill, "The Sale of Water by Meter in Berlin."

Photographic, 5a, Pall-mall east, S.W., 8 p.m.

Anthropological, 3, Hanover-square, W., 8½ p.m. 1. Mr. Osbert H. Howarth, "The Toltec Relics of Teotihuacan, Mexico." 2. The Rev. B. Danks, "Burial Customs of New Britain."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Sir Edward Braddon, "Australasia: a Vindication.

WEDNESDAY, DEC. 9 ... SOCIETY OF ARTS, John-street, Adelphi, W.C. 8 p.m. Mr. James Dredge, "The World's Columbian Exposition at Chicago in 1893."

Geological, Burlington-house, 8 p.m. 1. Prof. J. F. Blake, "The Rocks Mapped as Cambrian in Caernarvonshire." 2. Mr. Wm. Shone, "The Subterranean Denudation of the Glacial Drift: a Probable Cause of Submerged Peat and Forest Beds." 3. Mr. A. C. Nicholson, "High-Level Glacial Gravels, Gloppa, Cyrn-y-broch, near Oswestry."

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m.

Photographic Club, Anderton's Hotel, Fleet-street, E.C., 8 p.m. Mr. A. E. Tagliaferro, "Architectural Photography."

Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m.

Central Chamber of Agriculture (at the House of the Society of Arts), 11½ a.m. Annual Meeting.

THURSDAY, DEC. 10...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. Dr. Bridge, "An Hour with Mozart." (Illustrated.)

Institute of Architecture, Science, and Art, Dundee, 8 p.m. Mr. F. Grant Ogilvie, "Electric Lighting of Houses."

Electrical Engineers, 25, Great George-ssreet, S.W., 8 p.m. 1. Annual General Meeting. 2. Mr. W. H. Preece, "The Specification of Insulated Conductors for Electric Lighting and other Purposes."

Mathematical, 22, Albemarle-street, W., 8 p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m. Mr. F. W. Mills, "Practical Methods in Photographing Interiors."

FRIDAY, DEC. 11...Civil Engineers, 25, Great George-street, S.W., 7½ p.m. (Students' Meeting.) Mr. C. H. Wordingham, "Meters for Recording the Consumption of Electrical Energy."

Astronomical, Burlingtion-house, W., 8 p.m.

Clinical, 20, Hanover-square, W., 8½ p.m.

SATURDAY, DEC. 12...Botanic, Inner Circle, Regent's-park, 3¾ p.m.

Journal of the Society of Arts

No. 2,038. Vol. XL.

FRIDAY, DECEMBER 11, 1891.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CANTOR LECTURES.

Mr. A. P. Laurie delivered the second lecture of his course on "The Pigments and Vehicles of the Old Masters," on Monday evening, 7th inst. The lecturer fully described the various pigments in use in the 15th century, ending with a special description of the lakes.

The lectures will be printed in the *Journal* during the Christmas recess.

FOREIGN AND COLONIAL SECTION.

A meeting of the Committee of the Section was held on Thursday, 3rd inst., at 4.30 p.m. Present: Francis Cobb, Treasurer of the Society, in the chair; Sir Edward Braddon, K.C.M.G.; C. M. Kennedy, C.B.; Sir Erasmus Ommanney, C.B., F.R.S.; with Sir Henry Trueman Wood, Secretary of the Society, and E. Cunliffe-Owen, C.M.G., Secretary of the Section. The programme of papers to be read during the present Session was discussed.

Proceedings of the Society.

FOURTH ORDINARY MEETING.

Wednesday, Dec. 9, 1891; The Attorney-General, M.P., Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Braddon, Sir Edward N. C., K.C.M.G., 5, Victoria-street, S.W.
Cowan, Thomas William, 31, Belsize-park-gardens, N.W.
Fitzgerald, Prof. George Francis, M.A., F.R.S., Trinity College, Dublin.
Hotz, A. P. H., Leacroft-house, Staines.
Potter, Walter F., 440, Kingsland-road, N.E.

The following candidates were balloted for and duly elected members of the Society:—

Baird, John, Knoydart, Isle Ornsay, N.B.
Brettell, J. Henry, 11, Portman-street, W.
Butterworth, William, United States Patent-office, Washington.
Patterson, Myles, Oriental Club, Hanover-square, W.
Proctor-Sims, Richard, M.Inst.C.E., Bhavnagar. Kathiawar, India.
Wilson, James, M.E., Old Forge, Dunmurry, Co. Antrim.

The paper read was—

THE COLUMBIAN EXPOSITION OF 1893.

By James Dredge,

Member of Council; Member of the Royal Commission.

I.—Introduction.

I had the honour of appearing before you, a year ago, and of making the first public address on the subject of the Columbian Exposition of 1893 which had been delivered in Europe. On that occasion our Chairman suggested that, at similar intervals, until the close of 1893, it would be of interest to prepare other papers on the same subject, in which would be recorded the progress made during the preceding twelve months, and ultimately the measure of success achieved by the Exposition. Acting on this suggestion, I venture again to claim your attention, while I endeavour to describe the character, the actual condition, and the coming prospects, of the great work now rapidly advancing in Chicago. You may remember that, at the date of my previous paper, the smoke had scarcely cleared away from the battle-field at Washington, where different cities had been contending for the prize, and upon which Chicago remained the victor. It cleared away to disclose other and minor storm clouds, impending local difficulties, as well as broader differences between the Government representatives and those of the municipality. Then the Chicago Exhibition scheme tossed in troubled waters, as stormy as those of Lake Michigan. From the Eastern States, contempt and ridicule were poured upon it, and motives, that lay deeper than

those of angry disappointment, materialised themselves in a persistent flight of malicious telegrams and reports, intended to depreciate the prospects of Chicago and to prevent European co-operation; for European co-operation might mean to these intriguers extensive damage to American trade. These evil times are happily far enough removed to enable us to judge clearly of the attitude adopted by the people of Chicago, and by the gentlemen they have chosen to direct the affairs of the Exhibition; of their energy, determination, self-sacrifice, and steady advance in the face of great and discouraging difficulties. It may be affirmed with confidence that whereas, a year ago, the prospects of the Columbian Exposition were full of doubt and uncertainty, they are now assured; that the misunderstandings, jealousies, and suspicions that then suggested the possibility of shipwreck have been swept away; and that the executive, which twelvemonths since were only amateurs in exhibition matters, have so fully grasped the general aspect, as well as the innumerable details of the problem, that they have passed the stage of apprenticeship, and have proved themselves capable of filling the onerous position assigned to them. A year ago the general plan and organisation of the Exhibition were vague; to-day they are settled, down to minute points of detail: then, the designs for the buildings had not been prepared; now, all the important contracts have been let, and the whole area of Jackson-park is crowded with thousands of workmen. A year ago, in this country and on the continent, so far as the Columbian Exposition excited comment, it was that of contemptuous indifference, or of hostility emphasised by the effect of the McKinley tariff on the commercial mind, which had not realised that this weapon is a two-edged sword, as liable to wound those who wield it as those whose interests it is intended to strike. To-day the importance of the Exhibition is recognised; its extent and magnificence are no longer questioned; it has taken rank by anticipation as one of the great International Exhibitions of the century; and its potential commercial usefulness to British manufacturers is beginning to be understood. All these things are much to have achieved in so short a time, but more than that has been done. A Commission, representing the American Government and the Chicago directory, visited this country in July last, and were received in a manner that gave the greatest satisfaction to themselves and throughout the United States; their reception here undoubtedly prepared the way for their successful Continental mission. They visited almost every European country, and in each were received with welcome. France and Germany, Russia, Austria and Italy, Scandinavia, Belgium, and Holland—all these countries dismissed them with words of encouragement and promises, which were in most cases followed by action, and in all were sincere. The visit of these gentlemen to London was extremely well timed; it coincided with the appointment by the Government of a Royal Commission, and the special honour was shown to this Society of selecting its Council to constitute that Commission. I suppose we all of us realise the benefit of this selection to the Society; the distinction that has been shown it, and the value that it will be in the future, if the Council are enabled—and of that I think there can be no doubt—to report some three years hence that they have successfully acquitted themselves of the trust placed in them.

Even of more importance than the visit of the American Commission to London, was that of the representatives of the British Commission to Chicago last September. You will perhaps have read the report upon that visit, and will I trust agree that we all have the fullest reason to be satisfied with the prospects of the Exhibition, and to be more than content with the warm sympathy and kindliness, expressed both in Washington and in Chicago, towards this country. That this kindliness and sympathy were not empty forms of speech, was proved by the fact that in each instance the demands made on behalf of British exhibitors were granted to the fullest extent. The executive have, as a matter of course, laid down the wise rule to treat foreign applicants for participation without favouritism, and in the order of their application, but I think we may claim to be an exception to this rule, and to have commenced our connection with the Exhibition under conditions of friendship and goodwill which rise superior to the rigid limits of regulations, and call for our brotherly co-operation to aid in, as well to compete at, the Columbian Exposition of 1893.

When the Act of Congress was passed legalising the Exhibition as a Government undertaking, care was taken that, while the national Treasury was not hampered with liability, power was reserved for national supervision and control upon several very important points; and to take charge of the

Government interests a large Commission, composed of two members of Congress from each State in the Union, was appointed. The chief duties of this body were: to approve of the designs of the buildings and of the site selected; to satisfy themselves that the undertaking was on a financially sound basis; to compile the classification of exhibits; to allot space to home exhibitors and to foreign nations; and to control the proceedings of the juries, which are to be regulated by a system which they shall decide upon. Like many other committees, this national Commission entered on its duties with great enthusiasm and in full force of numbers, but it was soon found, as is not unusual, that the body was too large to be manageable, and before long its functions were delegated to a very small number of its members, who, with an equal number of the Executive Directory, constitute the supreme body, or Board of Control. The Government portion of this Board is represented permanently by the Director-General, Colonel George R. Davis, who has charge, subject to the Board, of the various matters above referred to, in which the Government hold control.

All executive matters relating to construction and management, before, during, and after the Exhibition, are vested in the Exhibition Executive, appointed by the Board of Directors, representing the guarantors of the city of Chicago, who have become responsible, in the first place, for the minimum sum of ten millions of dollars, and practically for the unknown supplementary expenses which most certainly will be incurred. As a matter of course the original estimates have been already largely exceeded, for the scheme of the Exhibition has grown under the hands of its creators, and the controlling bodies have applied to the central Government for assistance, not in the form of a grant, but as a loan, secured upon the future assets of the undertaking, rather than throw a further burden upon the citizens of Chicago who have made such large advances. With this part of the scheme we have nothing to do, though we may remark in passing that, in one way or another, the funds required, no matter how lárge they may be, will be forthcoming, whether from the national exchequer or from private subscriptions, and that in no event can any financial difficulty intervene—at least in no event for which a forecast is possible.

This part of the subject would not be complete without a reference to the organisation by which the Exhibition work is controlled. The Chicago Board of Directors consists of forty-five members, the officers of which are:—President, the Hon. W. H. Baker; Vice-Presidents, Messrs. T. B. Bryan and Potter Palmer; Secretary and Solicitor-General, the Hon. Benjamin Butterworth; Treasurer, Mr. F. Seeberger; Auditor, Mr. W. K. Ackerman; and Traffic Manager, Mr. E. E. Jaycox. The directory is divided into a number of working committees, of which the most important are the Executive, Finance, Grounds and Buildings, and Ways and Means. The Bureau of Construction comes under the immediate control of the Executive; the head of this very important department is Mr. D. H. Burnham, Chief of Construction, under whose direction all the details of the buildings are prepared, and the work carried out. In the same department are the landscape gardeners, Messrs. Olmstead and Co., whose work will be referred to later.

On the Government branch of the control are the officers of the Government Commission, nine in number, including the Director-General, Col. George R. Davis, who is the executive officer for the Commission. In his charge are the various departments of the Exhibition, chiefly referring to the arrangement of exhibits, installation, &c. The names of these departments and of their respective heads are as follows:—(1) Agriculture, Mr. W. I. Buchanan; (2) Horticulture, Mr. Saunders; (3) Live Stock, Mr. W. I. Buchanan; (4) Fisheries, Mr. J. W. Collins; (5) Mines and Mining, Mr. F. J. V. Skiff; (6) Machinery, Mr. Robinson; (7) Transportation, Mr. W. A. Smith; (8) Manufactures, Mr. J. Allison; (9) Electricity, Mr. J. P. Barrett; (10) Fine Arts, Mr. H. C. Ives; (11) Liberal Arts (of this the chief has not been appointed); (12) Ethnology, Professor F. W. Putnam; (13) Forestry, Mr. W. I. Buchanan; (14) Publicity and Promotion, Mr. M. P. Handy; (15) Foreign Affairs, Mr. W. Fearn.

Besides the foregoing committees and directors, there is a Board of Reference and Control; a Board of Lady Managers for the Women's section; and the Committee for the great series of Congresses to be held in connection with the Exhibition in 1893.

Finally come the members of the Board of Control for the United States exhibit, eleven in number, and all of them distinguished men. They are: for the Department of State—Mr. S. A. Brown, Chief Clerk of the State Department; for the Treasury Department—Mr. A. B.

Nettleton, Assistant Secretary; for the War Department—Major C. Comly; for the Navy Department—Captain R. W. Meade; for the Post Office Department—Mr. A. D. Hazen, one of the Assistant Postmasters-General; for the Department of the Interior—Mr. H. A. Taylor, Commissioner of Railroads; for the Department of Justice—Mr. E. J. Foster; for the Department of Agriculture—Mr. E. Willits, Assistant Secretary of Agriculture, and who is also chairman of the Board; for the Smithsonian Institution—Dr. G. L. Goode, assistant-secretary of that institution; for the United States Fish Committee—Mr. J. W. Collins; and for the Latin-American Department—Mr. E. W. Curtis. It will be seen from this list that every department of State will be efficiently represented in the Government buildings. Besides the various agents who have been dispatched to different parts of the world by the Executive as well as by the American Government, it may be mentioned that the Exhibition authorities are permanently represented in England by Mr. R. S. McCormick, recently Secretary at the American Legation in London, and whose offices are at 72, Victoria-street, Westminster; while several delegates have been dispatched to Europe by the Treasury Department in Washington to render such assistance and information as may be in their power, to the various Royal and other Government Commissions that have been, or will be, appointed in Europe to look after the interests of foreign exhibitors.

The names of many other gentlemen actively engaged upon the Exhibition in Chicago will be given hereafter in the course of this paper, and if they are omitted it will be due to oversight and not intention on my part. Just now public attention is concentrated on the work in progress at Jackson-park, and to this subject the present paper will be mainly devoted.

II.—The City of Chicago.

Before referring to the Columbian Exposition, it may prove of some interest to you this evening if I attempt to give a slight idea of the appearance and general characteristics of the city of which we are now hearing so much. It is said that a United States engineer officer, at the beginning of the century, who was employed upon the survey of the great lakes, reported that there was only one spot on which it was impossible to build a city on the banks of Lake Michigan; it is just on this spot that Chicago is situated. There was, however, good reason for this prophesy. A century ago the pathless wilderness terminated here in swamp and morass—land mingling with water like an unfinished fragment of creation; the sluggish, fever-laden creek, fed from the lake or from the inland water-shed, and altering the direction of its current with the season and the water level, spread over the adjacent low-lying lands and helped to complete the scene of hopeless desolation. But even two centuries ago this forbidding stream had its uses; the spirit of successful colonisation was then active in France, stimulated and carried forward by the fervour of religious enthusiasm that drove earnest men into the remote places of the earth, bearing aloft the Cross and planting strange truths in savage minds. These were the explorers and pioneers who have left traces of their work behind them through the broad lands that separate the lakes from the Gulf of Mexico; whose monuments remain in the names of cities and villages throughout Illinois and Louisiana; and in the names of many of the principal streets of the City of Chicago. Marquette and Joliet—priest and soldier—discovered the Chicago River late in the 17th century, and tested its usefulness as a way of reaching the Mississippi by the portage over the low divide that opposes a barrier to the chain of lakes from discharging into the Gulf of Mexico. The first survey of the district was made by Joliet in 1673; his companion died of malaria after a brief attempt to proselytise the local Indians. In these early times the name of the site was much the same as now; it had two meanings, according to whether the word was used by one or other of the tribes that frequented the unalluring spot—"Onion" or "Polecat." The fate of Marquette appeared through several generations to serve as an inducement for others of his devoted calling to seek malarial martyrdom on the banks of the Chicago Creek; and in their wake followed the traders, to traffic with the natives, but not to stay. The first permanent resident appears to have been a fugitive slave, who in the course of time did quite a handsome business as a fur trader. Meanwhile, troublous times were the portion of North America; wars with the Indians; French, Colonial, and British wars; and finally, the revolt against English despotism that laid the firm foundations for a great nation. It was only after the genius of Washington had brought the war of Independence to a triumphant conclusion, that the site of Chicago attracted any attention; this was

prior to the acquisition of Lousiana by the United States through purchase from France. British influence among the Indians around the Lakes was strong, and was exerted to the damage of the new Republic. In the words of an American writer, "It became necessary, with the acquisition of new territory, that the United States should make some demonstration of its strength, in order to counteract the pernicious effects of England's tactics." This demonstration took the shape of a fort that was built in 1804, and formed a nucleus for a small group of traders and other hardy pioneers to gather round it for mutual protection. So matters remained till the war of 1812, when a wholesale massacre of the garrison and the handful of settlers took place; the fort and dwellings were destroyed, and the silence of the wilderness was restored. Two years later, however, Fort Dearborn was rebuilt, the power of the Indians was broken, and a settlement was again attempted, this time with success, so that when—in 1818—Illinois was admitted as a State into the Union, Chicago was quite a thriving village. Civilisation—embodied by the tax collector—appeared in 1823, when, on behalf of Fulton County, in which Chicago was then situated, the sum of 11·42 dollars was obtained, showing that the rateable value of property at that time was 2,284 dollars, or less than £500. The real founders of Chicago appear to have been the Illinois and Michigan Canal Commissioners, a powerful corporation early in the century, and who possessed powers to lay out towns on the lands that had been assigned to them by the Government. Thus it came about that "Fort Dearborn Settlement," as the village had been called, passed out of existence, and the town of Chicago was called into being. The first plan of the new town and its surroundings (long since absorbed by rapid growth) was issued in 1830 on August 4th.

The history of the first few years of Chicago is that of all new settlements in the wilderness, with the exception, perhaps, that its progress, though at first slow, never received a check. In 1832, the first business building was erected by Mr. F. W. Peck, the father of one of the most prominent and wealthiest citizen families of Chicago to-day. About the same time the industry, now so famous—that of pork packing—was inaugurated, and, in 1833, the population had increased to 350, by which time it was considered that the settlement had developed sufficiently to be incorporated into a town. The United States Government, as early as 1833, commenced the harbour works, which have since assumed such large proportions, and it is worthy of note that when there were but 350 inhabitants, no less than four churches and four taverns had been constructed. It is not therefore surprising to learn that the first legislative efforts of the new town were directed towards the closing of the latter on the Sabbath, and the proper observance of that day; or that fines, that helped to swell the municipal exchequer, were levied for the infraction of these laws. The ambitious inhabitants of that time soon grew dissatisfied with being mere townsmen, and, in 1837, they succeeded in raising Chicago to the dignity of a city. In that year, when the first census was taken, it was found that the population had increased to a total of 4,170 persons. From this date the growth of the city of Chicago was phenomenally rapid, but it would occupy too much space, and be beside the present purpose, to attempt to sketch its history. I may therefore pass on at once to notice in a few words the fire of 1870, which destroyed more than three square miles of buildings, and rendered 98,500 persons homeless. This catastrophe was the turning point in the history of Chicago, for terrible as the visitation was, it swept out of existence, along with numerous fine and permanent buildings, thousands of wooden structures, and at the same time obliterated some miles of narrow streets. The total loss was estimated at nearly forty millions sterling. Modern Chicago dates from this conflagration, and ten years after it had occurred all visible traces of the devastation had disappeared, and the new era of construction, of which the city is so proud, had commenced.

To-day Chicago covers an area of 180 square miles; it has a population of over 1,200,000; there are 2,200 miles of streets within the city limits; there are 395 miles of street railways; and over 2,000 acres of public parks. Thirty-five district railroad companies have station accommodation in the city, and it is claimed that these railroads, with their branches and immediate connections, have a total length of more than half the mileage of all the ways in the United States. The Chicago river and its branches are crossed by sixty-one bridges, all, or nearly all, of which are turning bridges, so as to accommodate the constant movement of ships up and down the river. There are in addition several tunnels, by which the street traffic can pass without interruption, and this means of communication is on the

increase. Like most American cities, Chicago is laid out on the convenient but monotonous rectangular system. Its most important thoroughfare is State-street, which runs from north to south for a distance of 18 miles, or only three miles less than the distance between London and Windsor. To give you an idea of the dimensions of the city, I may add that 87th-street, which runs from east to west across its widest part, is 10½ miles long. Someday the ring of boulevards will be the glory of Chicago, and will add another to her many claims of superiority over the remainder of American cities. Some of these really magnificent roads are completed, and are lined with miles of handsome residences that attest the wealth and refinement of the citizens. When completed, this succession of boulevards will connect the twenty-eight parks which give to Chicago her favourite title of the garden city; I cannot say what will be the length of this system of boulevards, but it will certainly be longer than any other ring of boulevards in the world.

The number of houses added to Chicago last year would, if placed side by side, have made a solid frontage 51 miles in length. They numbered 11,640 structures, and cost nearly ten million sterling; this will give some idea of the rate of development of the city.

There are several peculiarities connected with the buildings of Chicago, to which reference may be made, as I think they are without parallel. One of these is the curious custom of moving houses, generally from a costly to a less expensive site. This operation is not by any means exceptional, as will be seen from the fact that during the year 1890, no less than 1,710 houses, with a total frontage of 33,922 feet, or about six miles, were shifted from one location to another. Most of the buildings so moved were of timber, but many of them were of brick, and some of them no less than four stories high; the average frontage for these transported dwellings was about twenty feet. The profession of house moving is a very old one in Chicago, as also is that of raising structures bodily to a sufficient height for allowing an additional story to be added at the ground level.

It would, however, be a task beyond the powers of the most enterprising contractor to shift or to raise the modern typical buildings, which claim to be larger and higher than any in the United States; and it would appear that there is good reason for this claim. Take, for example, the Masonic Temple, now nearly completed, which measures 117 feet by 114 feet, and has a height of 265 feet, divided into twenty storeys. Another towering structure, euphoniously styled "a new sky-scraper," is being reared, and which, although it will only have sixteen storeys, is intended to eclipse anything that has yet been attempted; and there are many of these enormous piles, not so lofty as those just referred to, and others still higher, either designed or commenced. Of those completed, the most remarkable are the new Chamber of Commerce building, with 500 offices, Temple Court with 400, the Mono building with 300 rooms. The Manhattan contains 900 offices; the Rookery more than 600; the Tacoma building has 500 rooms; and many others not much smaller. There are large numbers of such structures in the city, which impress by force of their size rather than by their architectural beauty, and it is refreshing to the uneducated western eye to turn to the older structures of importance, such as the City Hall and the Post-office building, which latter is to be pulled down ere long, and is referred to in the most recent guide to Chicago as "a great structure, but old fashioned." Its erection was commenced after the great fire in 1871.

The peculiar conditions of the soil have necessitated a special form of construction for all these lofty buildings. Beneath the surface ground, which consists chiefly of sand and extends to a depth of about 14 feet, there is a wide stretching bed of clay from four to six feet only in thickness. This clay is carried by some 40 feet of saturated soil, in many places little better than mud, and beneath is a solid bed of clay extending to a great depth. It was necessary either to found the buildings upon piles carried into the lower stratum, or to depend upon the thin bed of top clay. This latter course is now universally adopted, the greatest care being taken not to overload the apparently slight support which is available. It is of course impossible to have any deep basements, and, as said before, a novel form of construction is adopted. No continuous foundations are employed, but the piers or columns which support the building rest upon isolated bearings on the clay. These bearings consist of longer or shorter lengths of steel beams, placed close together and superimposed in several tiers, the interstices being filled with cement. The superstructures are, in nearly all cases, framed with steel columns, girders and bracing; the walls are mere shells

of stone, or brick, or terra cotta; they add nothing to the strength of the building, and merely act as screens; partitions are constructed of hollow terra cotta tiles; the floors of arches of the same material laid between the girders. All columns are protected by shells of terra cotta bricks, air spaces being left between them and the metal, in order to decrease the danger from fire by the presence of a non-conductor. In this way buildings are raised storey above storey, until they arrive at the enormous heights above mentioned. Instance the Masonic Temple with its twenty storeys, twelve or fourteen of which are arranged as spacious shops, the remainder being devoted to offices or for Masonic purposes; one peculiarity in this building is that all the domestic offices —lavatories, barber shops, &c.—are placed at the summit of the building. Of course a staircase is of but little use in such a structure; it is practically replaced by elevators, of which a dozen or more are to be seen in constant operation. It is worth noting that these elevators, which are run at speeds entirely unknown in this country, are worked like express and local trains, some stopping at every floor, and others at only certain stories. It is claimed that these monumental structures are cheaper and more convenient than those of lesser height: the ground within the centre of the city is so costly as to preclude the possibility of erecting ordinary buildings, and the undoubted advantage cannot be disputed that anyone who has business in the city can transact it within a very short distance of the Chamber of Commerce. Despite this, however, I am informed that a reaction is setting in against these lofty buildings, and even that legislation will before long interfere with their extension. A new development, too, is in progress in another direction; I have referred to the narrow margin of depth available for buildings founded on the upper clay. But now one building at least is to be constructed, the walls of which are to be taken down to the lower clay stratum forty feet beneath. This will, of course, involve very heavy masonry works to hold back the plastic soil that underlies Chicago; on the other hand, if the difficulties connected with this method can be overcome, a basement forty feet in depth will be obtained, and so much additional use will be made of the costly ground. The recent great buildings in Chicago are essentially engineering structures, not only as we have seen with regard to a system of construction, but also in respect to internal appliances. In all of them a very large amount of steam power is required for numerous purposes, such as electric lighting, heating, and ventilation, working elevators, lifting sewage, &c.

The sewage question is a very serious one in Chicago, and during the last thirty years the difficulties have been controlled, more or less successfully, by a series of expedients, which, like so many other things in the great city, are strikingly original. In early times, when the population was small, the discharge of sewage into the river, and thence into the lake itself, was not a matter of vital importance, and did not interfere with the water supply from the lake. In 1868 the very novel method of obtaining an uncontaminated water service, by tunnelling two miles beneath the bed of the lake and constructing an inlet at that distance, was successfully completed. The same system is now being imitated on a larger scale, a four mile water supply tunnel being nearly finished. For many years it has been illegal to discharge sewage into Lake Michigan, and theoretically this is avoided. It has been explained how, in the natural order of things, the Chicago river flowed sometimes into the lake, and how sometimes the lake flowed into the Chicago river. To establish this latter order as a fixed *régime* is the basis of the means adopted for preventing contamination of the lake water. The sewage is allowed to flow into the Chicago river—of itself a recognised evil and a standing menace to the public health. In order to reduce this evil as far as possible, very powerful pumping engines are kept in constant operation, raising the water from the river and discharging it into a canal which flows southward to the Illinois river, and thence to the Mississippi. The volume of water thus raised is sufficient at all times of the year to ensure a steady flow of the lake into the Chicago river, and the purity of the former is thus practically assured. But the fact remains that the river is nothing more nor less than an open drain that receives the sewage from the populous and busy city. The evil is so fully recognised that, in a very short time, works will be commenced by which the imperfect system of pumping will be exchanged for a rapid flow by gravitation of the Chicago river to the Mississippi. Fortunately the levels are so favourable that, considering the magnitude of the work, the necessary outlay will be moderate, and will not only alter the sanitary condition of Chicago, but will convert the city into a seaport. This scheme, which is now in

the hands of a drainage commission, is the construction of a canal, which shall be large enough to serve as a ship canal, and which, commencing at the Chicago river, will terminate at one of the branches of the Mississippi, and will thus open direct communication to the Gulf of Mexico. The levels of this new waterway will be so arranged that an enormous body of water will flow steadily from the lake southward, and thus restore to a minute degree the *régime* of that geological period when the Gulf of Mexico, and not the St. Laurence, received the overflow from the great lake system of North America. It will be gathered from what I have said, that in consequence of the slight variations in level afforded by the flat plain on which Chicago stands, only a very small proportion of the drainage can flow by gravity into the river. For this reason it has been found necessary to adopt means for raising the sewage from each building in which a basement exists, and in the great structures of which I have endeavoured to give you an idea, independent pumping installations are employed for this purpose. It may be of interest to mention that in almost every case the Shone system is in operation, and, I am informed, with perfect success.

No sketch of Chicago would be complete without a reference to the somewhat ghastly industry which is the corner stone of its prosperity—the great stockyards and packing works. To give some idea of the extent of this business, it may be mentioned that during 1890 more than 2,000,000 of cattle and nearly 6,000,000 of hogs were slaughtered; 311,557 railway cars were needed to bring these animals to the stockyards, and their estimated value was about £46,000,000 sterling.

The principal stockyards are situated about five and a half miles from the centre of the city in a south-westerly direction; they were opened in 1865, and occupy an area of 400 acres, half of which is devoted to the yards, while the remainder is occupied by railroad and sidings. Accommodation is provided for 20,000 cattle, 120,000 hogs, and 15,000 sheep; this stock is brought from all parts of the country in cars, containing, on an average, 20 cattle, 70 hogs, or 100 sheep. The business of the yards is to receive the stock and take charge of it until it changes hands, an operation which is very rapidly performed, and occupies about a thousand men employed by the Stockyard Company; a similar number in the service of 120 commission merchants, and about 300 buyers. As soon as the animals have been sorted, classified, and weighed, which latter operation is performed in fifty-ton scales, they are turned over to the buyers, who distribute them to their destination—the slaughterhouses. Here the work is minutely subdivided, and the rapidity with which the practised hands perform their work is astonishing; almost every part of the animal is utilised for some purpose or another, and the carcasses, after having been properly prepared, are taken upon tramways into the refrigerating rooms, where they are kept at a temperature of about 36 deg. From here they are taken on to the train-loading platforms, cut into quarters and placed in the refrigerator cars, whence they are distributed all over the country or shipped for export. There are a number of so-called packing companies in Chicago, the largest of them being that of Armour and Co. During the year 1890 this firm did a business amounting to £15,000,000 sterling; they killed 1,500,000 hogs, 650,000 cattle, and 350,000 sheep; they employed 7,000 workmen; they keep 1,800 refrigerator cars in constant service, and the floor area of their factory is 180 acres, with a storage capacity of 130,000 tons. A branch works of this company utilises the refuse from the slaughterhouses; last year they manufactured 6,250,000 pounds of glue and 9,000 tons of fertilisers and grease. The champion slaughterman of Messrs. Armour and Co. kills 5,000 hogs every day; but the greatest celebrity at this establishment is a steer, whose occupation is thus described by a Chicago writer: "He is perhaps the most depraved animal in existence. There is no element of brotherly love or patriotism in his nature. His duty at the yard is to guide droves of cattle to the slaughterhouses. He has mastered his little act, and reduced steering steers to a science. Every day he takes his post near one of Armour's packing-houses and waits until it is necessary to drive a herd of cattle up the viaduct to the killing-rooms. He then joins the drove, ingratiates himself into their goodwill, and tells them that he knows of a good pasture not far away. At his suggestion the cattle think about it, and finally resolve to let him lead them there. Bill, the Bunko steer, laughs softly, and a cruel look lights his eyes. He lopes off through the mud towards a large gate not far away. Following him are a hundred or more cattle, every one entertainining a vision of gently swelling hills covered with long wavy blue-grass and sweet clover blossoms. Bill leads

them to this gate, and allows the herd to go through it, while he steps aside and avoids the rush. As the dust of the rush clears off a little, a familiar figure is observed slowly strolling away from the gate. It is Bill; on his face is no remorse as he saunters back to his post of duty near a tall fence. He is then ready to betray a couple hundred more of his unsuspecting relatives."

Last year, a new stockyard company was organised at a greater distance from Chicago, and an area of 2,000 acres of land has been set aside for this purpose; at present, however these stockyards are not in operation.

After the packing and slaughtering industry, comes the grain trade of Chicago. From the agricultural regions of the Middle and Western States the grain is brought by train or by lake to Chicago, where it is stored in elevators for distribution all over the country. There are twenty-seven grain elevators in the city with a total storage capacity of about 29,000,000 bushels; the largest of these great warehouses, belonging to the Armour Elevator Company, contains 2,000,000 bushels; the average capacity of the others range from 1,000,000 to 1,500,000 bushels. The shipment of cereals from Chicago during 1890 were in round figures 12,000,000 bushels of wheat, 90,000,000 bushels of corn, 71,000,000 bushels of oats, and 12,000,000 bushels of rye and barley. About 8,000,000 bushels of this total were distributed by lake shipments, and this trade occupied no small portion of the vessels entering and leaving the harbour, and the total tonnage of which was 8,750,000, the number of vessels engaged in this trade being about 9,000. As all this very extensive shipping business is concentrated on the Chicago river and its branches, some idea may be gathered of the constant movement up and down the stream, and of the perpetual opening and closing of the bridges to the great hindrance of the street traffic. The river banks are lined with wharves, of which there are not less than forty-one miles. It is very evident that if this branch of carrying trade increases in the future, as it probably will, additional accommodation will be required, and by some means the lake front will have to be utilised for loading and unloading vessels.

I have attempted to give only a few general particulars of some of the principal industries and conspicuous characteristics of the City of Chicago. To enter into detail would carry this paper far beyond its proper limits, and would still fail in conveying accurate impression. No description, in fact, would do justice to this city of 1,200,000 inhabitants, almost every one of whom appears endowed with preternatural activity; which owns a street eighteen miles in length, almost a dead level for the whole distance, and on which are houses twenty storeys high; whose traffic is as noisy as it is ceaseless, both on the smooth running roped-worked railways and the ill-paved, jolting roads; where the roar of the locomotive and the scream of the lake steamer emphasize the fact that repose and silence are unknown, even in the dead of night; where a pall of smoke, the outpouring of a thousand factories and of ten thousand dwellings, reminds the Englishman of home. Picture all these things, and you can form some idea of Chicago, which has been raised in sixty years, by the indomitable energy of Americans, to the rank of the sixth city of the world in point of population.

Extend the city along a frontage of 22 miles upon the shore of Lake Michigan; imagine parks and waste land; factories, fine buildings and hovels, spreading over this extended front; add six miles of railway skirting the lake shore in the busiest part of the town, and remember that this vast succession of streets and houses is built upon the shore of a tideless sea, alive with ships, now sailing over waters as smooth and bright of hue as those of the Mediterranean; now fighting their way to or from port, in storms more sudden and severe than the Mediterranean ever knows.

Great as Chicago is, the period of her true greatness has yet to come. Its commencement will dawn when her inhabitants give themselves leisure to realise that the object of life is not that of incessant struggle; that the race is not always to the swift, but rather to those who understand the luxury and advantage of repose as well as of sustained effort. Real greatness does not depend on length of streets, nor height of houses, nor even on colossal fortunes; but rather on the wise application and equally wise conservation of energy and intellect. When Chicago ceases to be the city of Perpetual Haste, and adopts the pace which will be inevitably set for her by time, the names of her great workers will not be erased so early from the book of life, but will be preserved to give their beloved city many more years of really useful work. At present, I think there are no old men in Chicago, because they have no time to grow old; and giving themselves insufficient time for leisure, they have, as a necessary consequence, little opportunity for the higher culture which is born of leisure. Of course I am speaking of the general rule, to

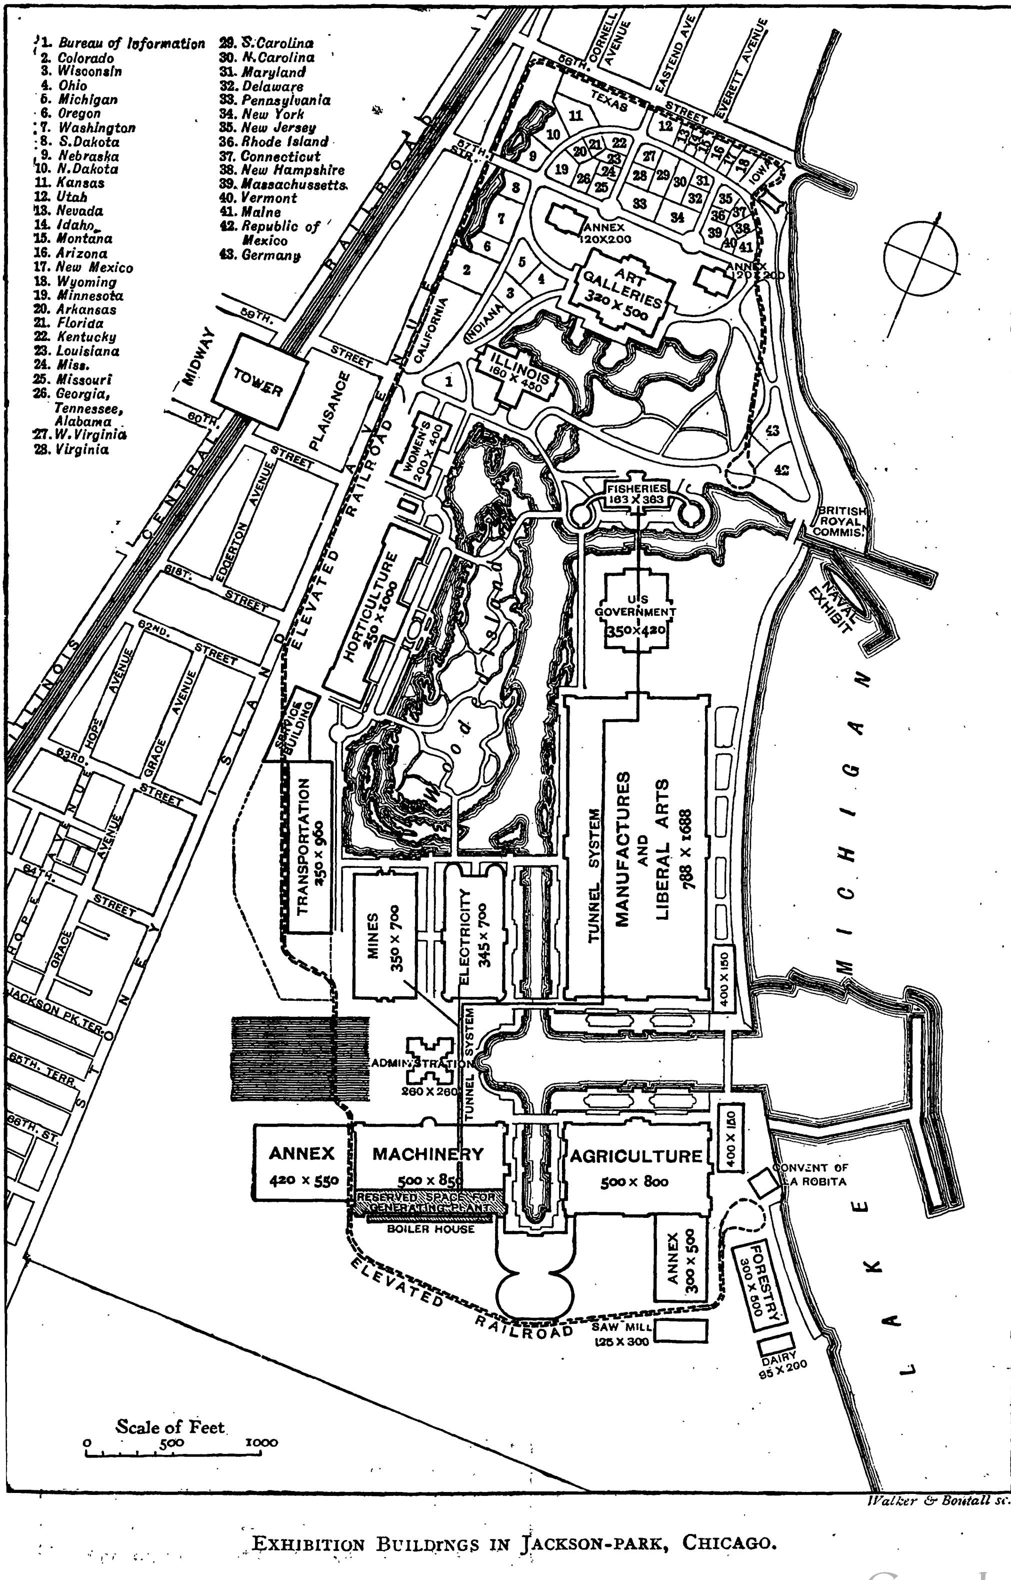
which there are many brilliant exceptions. It is probable that the Columbian Exhibition of 1893 will be the birth-place of this new phase of greatness of Chicago, for it will be full of every possible object-lesson, and will bring home to the inhabitants of the city, more forcibly than any other event could do, the fact that there is more in heaven and earth than had been dreamed of in their philosophy.

III.—General Plan of the Exhibition.

The site of the World's Columbian Exposition is about seven miles from the centre of Chicago; at first sight this comparatively large distance will appear objectionable, but no trouble will be caused to visitors, because the means provided for transportation, by trains, street railroads, and passenger steamers, will be amply sufficient to deal with the vast traffic expected. The site is really an ideal one, and of sufficient extent to satisfy even the most ambitious citizen of Chicago. It comprises Jackson-park, occupying 586 acres; Washington-park, a mile away, of 371 acres, and a strip of land called the Midway Plaisance, connecting the two, and contributing a further area of 80 acres. Thus there is a total of 1,037 acres available for the purposes of the Exhibition. Of this it is intended only to utilise Jackson-park and the Midway Plaisance for the buildings and grounds. Jackson-park is situated on the lake shore seven miles south-east of the city hall. Only a small portion of the northern part of this park had been laid out by the city prior to its acquisition by the executive; all the remainder was waste and marshy land, which has had to be reclaimed and adapted to receive the buildings. The large plan upon the wall shows the form of the park, the general disposition of the principal buildings, and their relative positions with regard to the lake shore. All that is most grandiose in the design, and most striking in architectural display, is concentrated near the south of the park on each side of a Grand Avenue terminating, on the one hand at the lake, and on the other with the Administration Building. A huge pier with a long **T**-shaped head, protected outside and to the north by breakwaters, encloses a harbour of sufficient extent to shelter all the smaller craft to be collected either for exhibition, or for the purpose of plying for hire. For the whole length of the Grand Avenue extends a broad basin with terraced slopes; in the basin the principal fountain display will be concentrated, and from it will be supplied the system of canals that runs throughout the grounds and expands into the lagoon situated in the centre of the park.

Although the façades of the various buildings facing the Grand Avenue are, each of them, the work of a different architect, the designs were prepared under such conditions as to secure a harmonious effect. Greater latitude in design was permitted in those structures which—more or less isolated—are not required to assist in aiding the effect of the principal perspective. The purposes of the various structures are marked upon the plan; to the south of the Grand Avenue are the Agricultural Buildings, with their stock-yards and annexes; a Forestry Building, and the Machinery Hall with its annexe, the former being connected with the Agricultural Building by a great classic colonnade. At the head of the Grand Avenue is placed the Administration Building, and on the north are the buildings for Manufactures and Liberal Arts, for Electricity, and for Mines and Mining. Westward and a little to the north is the Transportation Building; northward again, and facing the lagoon with the wooded island in the midst, is the vast Conservatory devoted to Horticulture and to Floriculture. North of this are the Women's Building, the Pavilion of the States of Illinois, and the Art Galleries with their annexes. The remainder of the park at this end, which is the area that had already been reclaimed by the Park Commissioners, is reserved for the pavilions of the various States, each one of which it is hoped will be represented. Returning southward by the lake shore, we come to a large space that has been set aside for the official pavilions of foreign countries, and here I may mention that the Exhibition Executive had reserved for this country the most advantageous site of all, the point of land facing the lake, and immediately to the north of the American Government Naval exhibit, about which I shall have more to say presently. North of the canal connecting the lagoon with the lake is the Fisheries Building; and south of this canal, extending to the north end of the Industrial Building, is a large area set aside for the United States Government, and on which their building will be erected. After this we arrive at the Great Hall of Manufactures and Industrial Arts, from which we started.

From the foregoing brief review it will be realised that the Exhibition comprises a large number of very important structures; of these I have only enumerated the most im



EXHIBITION BUILDINGS IN JACKSON-PARK, CHICAGO.

portant, but in the following list all the buildings to be constructed by the executive are set forth in detail, together with their dimensions, acreage, and estimated cost:—

Buildings.	Feet.		Feet.	Acres.	£
Mines and Mining ..	350	by	700	5·6	52,000
Liberal Arts	787	by	1687	30·5	200,000
Horticulture	250	by	1000	5·8	60,000
Electricity	345	by	700	5·5	73,000
Women's	200	by	400	1·8	24,000
Transportation	250	by	960	5·5	56,000
Administration	260	by	260	1·6	90,000
Fisheries	163	by	363	1·04	
Annexes	135	diam.		0·8	40,000
Agriculture	500	by	800	9·2	
Annexe	328	by	500	3·8	108,000
Assembly Hall	450	by	500	5·2	40,000
Machinery	500	by	800	9·8	
Annex	490	by	551	6·2	240,000
Power House	80	by	600	1·1	
Fine Arts	320	by	500	3·7	
Annexes	123	by	200	1·1	100,000
Forestry	200	by	500	2·3	20,000
Sawmill	125	by	300	0·9	7,000
Dairy	95	by	200	0·5	6,000
Live Stock	53	by	330	1·3	
Live Stock Sheds ..				40·0	30,000
Casino	175	by	300	1·2	30,000
Totals				144·8	1,176,000

In addition to the foregoing, there is the United States Government Pavilion, 350 feet by 420 feet, covering an area of 3·4 acres, and to cost £80,000; and the model battleship of the Navy Department, 348 feet long by 69·25 feet wide, and occupying ·2 acres in the lake; this exhibit will cost about £20,000. Finally, there is the Illinois State Building of 160 feet by 450 feet, or 1·7 acres, and which is to cost £50,000. It should be mentioned that the sum of £30,000 debited to the Casino (and which will probably be abandoned) in the above list includes the cost of the pier which has been already referred to. Of the principal buildings there will therefore be 150·1 acres, the estimated cost of which is £1,326,000. But besides these there will no doubt be several others, to say nothing of annexes; amongst them a large Music Pavilion and a Press Building are already being designed, and the very lowest estimate which the Grounds and Buildings Committee is justified in advancing is no less than £1,459,000. It is impossible to say at present how many State pavilions and buildings erected by foreign nations there will be in Jackson-park; the most moderate estimate places them at about eighty.

It will be interesting to compare the size of the Columbian Exhibition with that held in Paris in 1889. Leaving out Washington-park, which is at the disposal of the Executive, but which probably will not be used, Jackson-park and the Midway Pleasance make up altogether an acreage of 660. The Champ de Mars, the Trocadero, the Esplanade des Invalides, and the quays, were together 173 acres, so that including the harbour, which may be fairly reckoned as a part of the Exhibition grounds, the size of the World's Fair of 1893 will be four times as great as that of the Exhibition of 1889. We have seen that the principal buildings at Chicago will occupy a space of 150 acres; those of Paris covered 55 acres. Most of you will have a lively recollection of the fatigue inseparable from a thorough exploration of the Paris Exhibition, and you will therefore realise the necessity that will exist in Chicago for a complete system of passenger transit throughout the grounds; I believe that I may safely assure you the arrangements in this respect will be very ample and varied. I may now proceed to describe very briefly the leading characteristics of the principal buildings.

IV.—The Agricultural Building.

The Agricultural Building is of about the same dimensions as the adjacent Machinery Hall—500 feet by 800 feet—and covers an area of 9·2 acres. Its architecture is strictly classic, and harmonises well with the rest of the buildings facing on the Grand-Avenue. Its general cornice line is 65 feet above the ground level, and its chief features are large corner pavilions and central entrances connected all round by a lofty colonnade. In the centre of the building will be a rotunda 100 feet in diameter, and 130 feet high, and the exterior will be enriched by statuary placed at all the salient points. As at present designed, the interior of this building is not of a striking character, as it is divided into a large number of small galleries. I am given to understand, however, that this arrangement is not definite. Adjoining the Agricultural Building are several others: an annexe, 328 feet by 500 feet, to receive overflow exhibits; a sawmill, nearly an acre in extent; and a Forestry Building of 2½ acres.

The names of these buildings indicate their purpose, as also does that of a dairy, half an acre in extent, and in which it is intended that all the most advanced appliances and methods of American dairy farming shall be exhibited. South of the Agricultural Building are the

yards and sheds for live stock, the latter covering no less than 40 acres; while the whole space devoted to this section of the Exhibition will be at least 60 acres. There can be no doubt that, to the large majority of inhabitants of that vast district devoted to cattle raising, of which Chicago may be considered the metropolis, this section of the Exhibition will be of special importance. I am informed that the closest attention is paid—by those interested in this industry in America—to the cattle breeding of this country; and that the export of pedigree cattle in the United States is a very large one. If this be so, the stock-yard section should also be specially interesting to our own cattle raisers; and official assurance has been given that every possible facility to intending exhibitors in this section by the Transportation Committee. It should be remembered that pedigree stock is imported free into the United States. Messrs. McKim, Meade, and White, of New York, are the architects for this building and annexes.

V.—The Machinery Hall.

The Machinery Hall is 500 feet wide and 850 feet long; with its annexes it is to cover an area of about 17 acres. At one end and connected with it is an annexe 500 feet wide and 550 feet long. The position of this very important building is shown on the plan, where it will be seen that its principal façade faces on the Grand Avenue; it is this façade upon which the chief architectural detail is concentrated. Beyond it and at the head of the short canal branching from the basin, the façade of the Machinery Hall is connected with a colonnade that adds greatly to the imposing effect, and at the same time serves as a screen to separate the stock yards of the Exhibition from the rest of the grounds. This colonnade, which is of considerable extent, is carried as far as the Agricultural Hall, so that the visitors can pass from one to the other without being exposed to the weather. The general scheme of the main building of the Machinery Hall behind the ornamental exterior is rectangular, and the vast space is divided into three galleries, each about 130 feet span; there will, therefore, be no very extensive engineering work in this building. In the centre of the hall the three galleries just referred to will be crossed by a transept of about the same width, and the intersections are marked by the construction of three domes. At each corner is a large pavilion with a domed roof; entrances to the building will be provided in each of these pavilions, but the main portals will be on the north and east sides where the classic porticoes will be placed; these porticoes will be flanked by towers 200 feet in height. Between the corner pavilions and the central entrances on the north and east sides, the exterior will consist of open loggias or colonnades two stories in height and with internal galleries; these are covered by a flat roof. A similar flat roof covers the outer part of the building on the south and west sides, but as these sides will not be so much exposed, elaborate architectural effect is dispensed with. The building will be lighted by skylights over the flat roofs, and by raised lanterns at the top of the main arched galleries; the greater portion of the domes will also be glazed. Most of the framing of this building will be of steel, though all the skeleton of the exterior is of timber very cleverly arranged and covered with cement and "staff," in the same way as all the decorative effects of a similar nature are obtained throughout the Exhibition. The foundations, however, are of wood, designed on the same lines as those already referred to when I was speaking about the great buildings of the city. Only as the structures at Jackson-park are temporary, it was not considered necessary to incur the considerable cost of iron and concrete platforms, but precisely the same method of distributing the weights has been adopted except in those cases where the uncertain nature of the ground rendered piling a necessity. Extensive galleries will be erected around the interior of the building at the same height above the ground as the galleries of the loggias before mentioned; they will be reached by eight main staircases and a number of subsidiary ones, as well as by elevators. The annexe to the Machinery Hall will be built largely of wood, and will have no pretension to architectural elaboration. On the south side of the main building a boiler-house will be erected, 80 feet wide and 600 feet long. In this building will be generated all the steam required for the great power station that is to furnish the Exhibition and grounds with the necessary energy, calculated at present at 25,000 horse-power. The engines by which this force is to be generated will be placed together within the Machinery Hall, a sufficient area on the south side being reserved for that purpose. It is intended that both engines and boilers, with all the auxiliary machinery, should constitute exhibits, and as this is a point upon which some of our manufacturers will certainly feel considerable interest, I repro-

duce here the official information as to the terms on which steam-engine exhibits, intended to form a part of this power station, will be received. "Engines aggregating 25,000 indicated horse-power will be required. These must all be compound, either cross or tandem, horizontal or vertical, or triple-expansion. These engines may be of any automatic type, high or low speed, and must be condensing, manufacturers to furnish condensers. Steam pressures will be of 125 lb., 150 lb., and 200 lb. per square inch; either pressure may be used at the option of the exhibitor. The work to be done will be generating electricity either for arc or incandescent lighting, power transmission, or driving line shafting. No engine shall be of a smaller capacity than 150, nor of a greater than 1,000 horse-power. If it is desired to drive line shafting, engines should be of low speed and capable of working up to 325 horse-power, with an economical working load of 160 horse-power. For operating dynamos they may be of any type, and capable of developing from 150 to 1,000 horse-power. The basis on which engines will be accepted will be as follows:—Such engines are to be consigned by the manufacturers to the World's Columbian Exposition, and will be placed upon foundations free of all cost to the executive, which will prepare foundations of concrete, according to drawings furnished by the manufacturer, will make all steam and water connections, maintain, operate, and furnish all supplies, such as oil and waste, during the Exposition; the manufacturer to remove the engine at the end.

"The engines will remain the property of the exhibitor, and will be considered as exhibits in operation. Exhibitors will be required to furnish operating engineers, whose wages will be paid by the Executive, and who will be subject to the direction at all times of the Chief of Construction. Such manufacturers as decide to exhibit engines under the above conditions should make application without loss of time to their respective commissions."

This very large power station will be utilised not only for transmission of machinery in motion in the Machinery Hall, but for distributing current throughout the various buildings and grounds, for power, lighting, and other purposes. It should be mentioned in this place that it is the present intention of the Executive to introduce a complete novelty for driving machinery in motion. The great success that has attended the distribution of energy by compressed air on the Popp system in Paris, has encouraged the Executive to employ this means of operating the machinery in motion. The advantages attending this innovation will be very great; not only can cold air machines and refrigerating machinery be supplied direct, but the Machinery Hall will be kept cool—a very important consideration during the summer. Besides this all the many annoyances to exhibitors and visitors arising from leaking steam pipes and defective joints will be avoided; leakage will be an advantage instead of an inconvenience (except as regards loss of power), and a great complication in the mains beneath the flooring will be avoided.

If this project is put into execution, a large amount of air-compressing machinery will be required; this will be treated by the Executive much in the same manner as the engines already referred to above.

Returning to the power station, it will be realised that the greater part of the 25,000 horse-power will be required to drive electric current generators, which will also be exhibits. A very elaborate system of underground mains will be laid in tunnels constructed so as to reach all the buildings requiring light or power, and every part of the grounds. A circular electric elevated railway will be constructed so as to include the principal buildings, and as on this, very frequent trains will be run, a large amount of power will be consumed. Current will be delivered to all the separate buildings of States and foreign countries, and such power (of course with some exceptions) as will be required to show machinery in motion in various parts of the grounds will be furnished from the central station. It is the intention of the Executive, during the Exhibition, to subject —if the exhibitors approve—all the machinery employed in connection with the central station, to an elaborate and careful system of trials, so that the actual and relative efficiences may be ascertained.

The Electrical Department, the chief of which is Mr. F. Sargent, desires to give every possible encouragement to foreign electrical engineers and contractors, to induce them to compete for the contracts of laying mains, providing lamps, generators, motors, and other plant that may be required in carrying out the electrical system of the Exhibition, and also to tender for the maintenance of such work during the continuance of the Exhibition. Such competition would no doubt be of great interest to some of our own industrials, but I am informed that if such work were done as an ordinary contract, and not as an exhibit, the tariff regulations would make it difficult, if not im-

possible, for any foreign contractor to compete. If, therefore, the Exposition authorities desire such foreign co-operation seriously, it rests with them to meet these difficulties so as to place foreign manufacturers on equal terms with those of the United States.

The space reserved for Great Britain and her colonies in the Machinery Hall is 40,000 square feet, about the same space which she occupied at the Centennial Exposition of 1876. Whether under the existing conditions of trade and competition with the United States it will be possible for us to occupy this large area, it is too early to predict; it must be borne in mind that any machinery shown in the Transportation, Electricity, or Mines Buildings will be placed there at the expense of Machinery Hall. Still, I think that there are sufficient manufacturing engineers in this country whose interests in the United States—either actual or prospective—or with other countries, are important enough to induce them to make a fair, though perhaps not a representative, display. The architectural work of the Machinery Hall is by Messrs. Peabody and Stearns, of Boston.

VI.—The Administration Building.

The Executive of the World's Columbian Exposition have determined that the most elaborate structure to be erected on Jackson-park shall be that devoted to administrative purposes. The determination is commendable for several reasons. In the first place the idea is novel, and well chosen novelty on the heroic scale is most desirable in international exhibition design. The Paris Exhibition of 1889 will long be remembered by many millions, chiefly on account of the Eiffel Tower; the popular souvenir of the Columbian Exposition of 1893 will undoubtedly be its Administration Building. Occupying a superb site, the most conspicuous upon the grounds, it will prove a triumphant answer to those prejudiced and Transatlantic critics who have persistently declared that nothing good can come out of Chicago. It is true that New York may claim the credit of the design, for with broad-minded policy, the Executive had recourse to the architect they considered best able to carry out the conception, regardless of possible local opposition. But the idea belongs to Chicago, and the money by which it will be carried out is furnished by Chicago.

Approaching in dimensions, and, in some opinions, surpassing in architectural beauty the Capitol at Washington, the Administration Building will form a fitting monument to the energy of the city to whom the responsibility of holding the celebration was intrusted. And in this probably lies the peculiar fitness of erecting this building, that it may serve as an unmistakable proof of the appreciation by Chicago of the honour rendered to her by the nation, and enable her to receive the representatives from all parts of the United States (as well as from all parts of the world) in a palace such as has never been before seen at any exhibition. The pity is, that so great an expenditure having been incurred in giving form to the ideas of the architect, it should be useful for only a few months, and that it should partake of the transitory character of all other buildings upon Jackson-park.

The Administration Building will be placed at the western end of the Grand Avenue. It is rectangular in plan, and the main façade faces eastward. The building measures 260 feet 6 inches on each side. The lower portion, which serves as a base for the dome, is made up of four pavilions, each four stories in height, and separated from one another on each side by the great entrances.

The roof of these pavilions is flat, and all four are connected by exterior galleries, forming together an extensive promenade for visitors. The pavilions measure 84 feet on a side, leaving a space of 92 feet between, the centre of which is occupied by a round-headed gateway, The entrances to the pavilions are within the rotunda, arranged symmetrically around the circular space beneath the dome. The same entrances give access to the stairways leading to the promenades around the dome. Separate staircases are, of course, provided for the different offices. These stairways are approached by a hall or vestibule 30 feet square. In each vestibule are two large elevators, that will not only serve the offices, but will convey visitors to the promenade above, and to the higher gallery running around the springing of the dome. The pavilion will contain the offices of the President of the United States Commission and those of the Director-General: the fire and police departments, and the offices of the secretary and clerks of the Executive Board, the offices of Public Comfort, the Bureau of Publicity, and a restaurant, the Ambulance Department, the Foreign Department, Information, &c. Besides this, there will be committee-rooms and board-rooms, a bank, and all the various accommodation required for administrative

purposes. Although these pavilions are divided into four storeys, no such arrangement is indicated on the exterior of the building, which is designed in one scheme of Doric architecture, to form a base or plinth surmounted by a massive balustrade, the piers at each angle being crowned with sculpture. The great doorway is also flanked with sculpture, and statues about 14 feet in height crown the piers on each side of the entrances, between them being panels bearing appropriate inscriptions. The second stage of the building that constitutes the actual base of the dome is about 70 feet in height and octagonal in plan; it carries up the central portion of the building from the ground floor. The architecture is Ionic, and the chief feature is a pavilion at each corner surmounted by a small dome, and with groups of statuary over every pier. These pavilions are connected, on the four sides, with an open colonnade 20 feet in width and 40 feet high; the columns will be four feet in diameter; this colonnade will serve as a public covered promenade. From this stage rises the dome, at first—for a height of 30 feet—with vertical sides and octagonal in shape. This part is divided into panels, three on each face, the panels being filled with medallions bearing famous names. Above the mouldings over these panels is a second set of panels, enriched with garlands, and at each angle of the octagon with sculptured eagles. From this level the dome, 120 feet in diameter, curves till it reaches a height of 264 feet from the ground, the distance between the heavily moulded ribs corresponding to that between the styles beneath. The spaces between these ribs, nearly to the top of the dome, are to be filled in with burnished metal, and the dome is surmounted with a skylight. Gilding and rich colour will be lavished on this part of the building to emphasize the effect sought to be produced, that the Administration Building is the central and most important part of the Exhibition, although of itself it contains no exhibit, and constitutes one only in the sense that it will show how far the science of architecture has developed in 1893. The architect of this splendid building is Mr. Richard M. Hunt, New York, President of the American Institute of Architects.

VII.—The Liberal Arts Building.

The Liberal Arts Building, with an area of 30½ acres, will be essentially the monumental palace of the Exhibition. Its architectural features, especially those of the south façade facing on the Grand Avenue, are very elaborate; this part of the work was designed by Mr. George B. Post, of New York. The main entrance will be at the southern end, but there will be great portals on each side midway of the length, and a colonnade runs around the building. Originally it was intended that a series of comparatively narrow roofs within the external architectural decoration, should inclose on all sides a great inner court broken in the centre by a dome 370 feet in diameter. It was, however, soon realised that the space occupied by these inner courts could not be spared, and the whole area will now be roofed in by a single span 368 feet wide and 208 feet in height, the narrow surrounding galleries being retained as in the original design. The great span is the same as that of the Machinery Hall at the Paris Exhibition of 1889; it is, however, 61 feet higher, and the building is of considerably greater length. It has been designed by Mr. Shankland, one of the chief engineers in Mr. Burnham's department. It may be interesting to mention that the entire width of the Exhibition of 1851 was less than that of this building, and its maximum height was only half as great. The side galleries, which inclose the great central gallery are three in number on each side, and respectively 52 feet 3 inches, 107 feet 9 inches, and 46 feet in width; the clear height of the largest of these spans will be 97 feet. An upper gallery, 25 feet above the ground, will be constructed throughout the whole length of the smaller spans, so that a large additional amount of floor space will be available. Between the great girders of the central roof, galleries will also be placed, 25 feet above the ground, and projecting into the hall, from which visitors may obtain a good view of the Great Gallery and its varied contents from a commanding position. It is in this building that the largest and most important space, amounting to 120,000 square feet, has been allotted to Great Britain and her principal colonies. The greatest liberality has been shown by the Exposition Executive with regard to the arrangement of exhibits by foreign nations within their respective sections. It was the intention of the classification committee that all objects exhibited should be arranged according to their character and not by nationalities; but this obviously inconvenient arrangement has been set aside, and Great Britain will be at liberty to arrange all her industrial exhibits within her own section, following of course the general classification that has been laid down. If, therefore, it

should unfortunately happen that the co-operation of this country is not so extensive as we hope, we shall be represented in only three or four groups—chiefly those relating to Industries, the Fine Arts, and Machinery. At the same time space has been reserved for us in all of the principal buildings, so that, if necessary, British exhibits will be distributed throughout the main buildings, always, however, being grouped within the space allotted, so as to make a number of important groups.

The classification of exhibits within the Manufactures and Liberal Arts Building is so wide and varied that it must include a number of objects which are specialities in this country, and which may be shown greatly to the profit of manufacturers even as regards sales in the United States. Furniture, glass and china, art metal work, tissues of various kinds, travelling equipments to a limited extent, hardware, and cutlery, and in short all the large class of goods which Americans purchase in this country should meet with a large demand.

A passing reference may be made to a strictly non-commercial class of exhibits which will be collected in this building, that relating to ethnology and anthropology; this section will be under the charge of Professor Putnam, and it is to be hoped that the valuable collection which he is making will be supplemented by large contributions from Europe. A detailed reference is made to it later.

VIII.—The Electricity Building.

The Electricity Building covers an area of 250,000 square feet, and is estimated to cost 130,000 dols. The architects are Messrs. Van Blunt and Howe, of Kansas City, and the design appears not only admirably adapted for its purpose, but sufficiently well proportioned and ornamental to take a front rank among the many splendid buildings on Jackson-park. The main entrance to the building faces on the great central avenue, near the Administration Building. The principal architectural feature at this end of the building is a portico and colonnade extending for the whole width on each side of the monumental entrance, over which are inscribed a series of names famous in the annals of electrical science. The main tower at this end reaches an elevation of about 200 feet, those at the sides being somewhat shorter and of more slender proportion. Except for the two large bays at the back of the building, the plan is rectangular, the length being 690 feet, and the width 345 feet. The centre of the building is occupied by a large hall, running from end to end, and about 115 feet span, flanked by a double row of columns and aisles 70 feet in width. Important entrances will occupy the centre of the building on each side, and access is gained to the galleries by broad stairways occupying the middle of the building. The end bays will be glazed so as to afford as much light as possible. Large as are the dimensions of this building, it may be confidently expected that they will be insufficient to accommodate the exhibit. Electricity and its practical applications will be one of the largest and most important sections of the Exhibition, and during the next two years there will, doubtless, be many new developments not yet brought into a practical form. In connection with this building, some general particulars of the scheme of electric lighting at Jackson-park may be given. The plans have been elaborated by the chief electrical engineer, Mr. Sergeant, and his proposals have been accepted by the committees on electricity, on the grounds and buildings; and by Mr. Burnham, the chief of construction. As upon every other point, so in this matter of illuminations, the Executive appear determined to surpass all that has been hitherto attempted in this direction at international exhibitions. In 1889 only three of the main buildings were opened at night to the public and furnished with electric light. It has now been decided that complete arrangements shall be made for lighting every one of the great halls at Jackson-park as well as the extensive grounds. The scheme elaborated up to date refers to nine of the great buildings, and comprises 5,180 arc lamps of 2,000 candle-power each, and 14,700 incandescent lamps of 16 candles. Except in the Fine Arts, the Administration, and the Women's Buildings, arc lights will be employed and will be distributed as follows:—In the Machinery Hall there will be 600; in the Agricultural Hall, 600; in the Electric Building, 400; in the Mines and Mining Building, 400; in the Transportation Building, 450; in the Horticultural Hall, 400; in the Forestry Building, 150; and in the Industrial Arts Building, 2,000. As just stated, there will be no arc lights employed in the Fine Arts Buildings, but in their place the interior will be lighted by 12,000 incandescent lamps. The Administration Building will be illuminated in the same manner, and about 10,000 sixteen-candle lamps will be required for this purpose. The lighting of the Women's Building will be

mixed, and comprise 180 arc lamps and 2,700 incandescent lamps. In addition to the lighting supplied by the authorities, any exhibitor who requires it will be able to obtain current for lighting his display, in any manner he thinks fit, conformably with the lighting regulations. It is presumed that this current will be furnished to private consumers at a fixed and very moderate tariff. The arrangements for lighting the grounds, for the illuminated fountains, for private lighting, and miscellaneous purposes, have not yet been completed. It is decided in principle, however, that every one of the numerous pavilions and official buildings will be abundantly supplied with electricity, so that any reasonable amount of light can be obtained, and gas will be practically, if not actually, unknown at Jackson-park as an illuminant. It is intended, amongst other novel applications of the electric light, to illuminate the harbour inclosed within the pier and breakwater, already referred to, either wholly or in part, with submerged incandescent lamps so arranged that the light may be thrown upwards towards the surface of the water. Such an arrangement would undoubtedly consume a large amount of power, but the effect would be very striking and attractive.

It should be mentioned that already a large amount of electric power is available on the grounds, an extensive installation having been completed and put in operation. It has been ordered by the Executive that the contractors are not to be allowed to use steam power, but that they must work all their machinery by electricity; this has been done to reduce the risk of fire during the progress of the work. All the sawmills set up for the Industrial Building are driven by this means, and the contractors for the Administration and Horticultural Buildings are already using a considerable amount of the same power. There are at the present time at least a dozen motors driven by current furnished from the temporary central station. This is an entirely novel application of electricity in connection with exhibition buildings.

A very considerable amount of current will also be required for lighting the grounds through the long winter nights, during which work will be carried on continuously by different shifts of men. The arrangements made between the Executive and the directors of the labour unions, limit the length of daily work to eight hours. By this means the Executive is confident that they will carry the work forward to its conclusion, without any interruption due to labour troubles.

IX.—Mines and Mining Building.

The Mines and Mining Building, which adjoins the Electricity Building on the north side of the Grand Avenue, covers an area of 5·6 acres. Its architecture harmonises with the rest of the principal structures. It presents a suggestion of early Italian Rennaissance, treated somewhat liberally by the American architect. The main entrances, of which there are four—one in the centre of each side—are richly embellished with sculpture, symbolical of the uses to which the building is to be employed. A large square pavilion surrounded by a low dome, marks each corner of the building, and between the pavilions and the several entrances are richly decorated arcades, projecting beyond the outer walls, so as to form a loggia on the ground floor, and a wide gallery 25 feet above. These covered galleries are 25 feet wide, and are each of them 230 feet long; access to them will be obtained by various smaller entrances. It may be mentioned that the effect of this part of the building will be extremely rich, as marble facings will be used throughout in great variety. This marble will constitute exhibits, and will have a marketable value at the end of the Exhibition. The arched ceilings of the loggia will be heavily moulded in plaster, and will be highly coloured, to conform with the general scheme. The fronts of the building are 65 feet in height to the top of the cornice, while the main central entrances reach a height of 90 feet. The same scheme of treatment, though carried out in a somewhat similar manner, is applied to the longer sides of the structure. In plan the Mines Building is rectangular; it will comprise a main hall 115 feet wide and nearly 100 feet in height; on each side will be an aisle 57 feet 6 inches wide and 50 feet high. The whole of this will be constructed in steel in a bold and somewhat novel manner. Around the main hall runs a wooden structure 60 feet in width and 60 feet high; a gallery, the height of which corresponds with that of the gallery over the loggia, will run around all four sides of the building, thus inclosing the main hall. Access to the galleries may be obtained by broad stairways placed on each side of the entrances. This building, which, as has already been said, presents some striking originality, was designed by Mr. S. S. Beman, of Chicago; its estimated cost is £52,000. There

can be no doubt that the contents of this building, so far as the United States exhibits are concerned, will be of the highest possible interest. Within it will be grouped all varieties of raw mineral products; of metals obtained from the ores; manufactured metals; mining and metallurgical machinery; everything, in short, that will serve to illustrate the vast industries of mining and of metallurgy. The United States is so rich in natural mineral resources of almost every kind, and its requirements are so large and varied, that the mining and metallurgical industries have been developed to a remarkably high degree. More than this, as the natures of similar ores differ widely in various parts of the country, and as the conditions under which they can be obtained and converted differ almost as widely, it follows that a great range of processes have been developed in America, or adapted from Europe, and that if these are fairly represented at Chicago, the most advanced practice of the mining engineer will be fully illustrated. Probably we may not have much to display with advantage in this building; in some respects American practice is of necessity far in advance of our own; in others, commercial reasons suggest the prudence of not exhibiting those of which this country makes a speciality. There is, however, one point to which I should like to direct special attention. One of the most interesting exhibits in this building will be a large series of collections of ores and minerals systematically arranged. Almost every metalliferous State in the Union possesses complete and carefully arranged collections of this nature, and these combined will illustrate the mineral resource of the country. It is earnestly desired by the chief of this department to add similar collections from different parts of the world, which would be carefully guarded, and every possible assistance guaranteed to the lenders.

According to the general scheme of the Columbian Exposition, and under the classification provided for the installation, many branches of the mining industry, heretofore incorporated in other departments, will be placed in their legitimate positions in the Mining Building, so that, when the exhibits shall have been properly collected, classified, and arranged, the department will be a comprehensive and complete exposition of all the great mineral treasures of the earth, and the methods employed in their search, treatment, and use.

An inspection of the classification of Department "E"—Mines and Mining—gives some idea of the variety of exhibits included. The raw materials and the natural products to be exhibited in the Mining Department will constitute the basis of every other exhibit made, except those of Agriculture and Horticulture. The groundwork of all the arts, sciences, and mechanical industries will be comprised within the walls of the structure dedicated to Mines, Mining, and Metallurgy. All of the precious minerals, and minerals, precious stones, mineral fuel, building stones and marbles, clays and sands, salts and pigments, as well as the machinery, implements, and appliances employed in their conversion to use, will be fully represented.

The subject of coal will be treated on very broad lines. It would be impossible to accept for exhibition purposes all the really meritorious specimens that can be secured in the United States for the purpose of demonstrating the coal resources of that country. The treatment will be comprehensive, and the display based upon the distribution of the great coal-fields that are so conspicuous in the geology of the United States. The industry is of gigantic proportions, involving the investment of many millions sterling, and the employment of hundreds of thousands of people. The display of coal at the Exposition will be qualitative rather than quantitative. The different varieties, produced at different localities, will be shown, together with the chemical analysis of each, and the results of tests determining their economic value and adaptability to various purposes. The coal resources of the different States will be shown by geological maps and drawings exhibiting the stratification, &c., which will render apparent the extent and accessibility of the vast number of coal beds and veins which underlie the entire Continent.

As regards iron, efforts will be made to have an adequate exhibit of that great branch of industry. Without considering the contributions that will be made to this division by foreign Governments, the United States, which is now the first nation in the world in iron production, will provide a display of the greatest interest and benefit to the manufacturing world. The development of the iron resources of the Southern States within the past few years, no less than the attention which has been devoted to this particular industry in the west during the same period, gives a leading interest to this product. It is intended to arrange the exhibit with the fullest apprecia-

tion of the magnitude and importance of the iron industry, with ample data as to the location and extent of the greater deposits, the analyses of the ores, and statistics, not only based upon the operations of the past, but in a degree indicating the extent to which they may be carried on in the future.

Every provision has been made for the installation of the ores of the precious metals and cabinets of specimens contributed by private individuals, associations, and technical and mining schools. These will be arranged with minute care as to detail. States, individuals, collectors, and colleges in the United States will undoubtedly vie with one another in their endeavour to establish the superiority of their respective collections, or to demonstrate the value of certain mineral districts or areas. Many ingenious devices and designs will be utilised by the several States, Territories, and countries to illustrate the magnitude of their auriferous and argentiferous deposits.

The mechanical appliances of mining pans, cradles, and rockers, modern and complicated amalgamating, concentrating, and smelting machinery. Crushers, centrifugal quartz mills, stamps, rolls, jigs, frue vanners, concentrators, roasting and melting furnaces, reverberatory and matte furnaces, bullion cars and pots, crucibles and ladles—in short, the entire plant of milling, smelting, and refining works of different descriptions will be shown. It is intended to demonstrate the process of extracting precious metals in the most thorough manner. Gold and silver bearing rock will be passed through the various stages until the pure metal is exposed. The mining machinery manufacturer will be given ample opportunity to display the excellencies and demonstrate the usefulness and economy of his machines.

Plans for, and the best methods of, equipping assay offices will be presented and illustrated. Melting and scorification furnaces, with muffles, cupels, &c., with melting pots and fluxes handy for the production of the assayer's "button," volumetric and other test methods, rolls, and small crushers for preparing test lots of ores, the most delicate instruments of precision—these and the associated appliances of metallurgy will be exposed.

Marbles, agates, jaspers, onyx, silicified wood, &c., will be collected. Numerous machines and tools for channelling, sawing, lifting, turning, and polishing granites, sandstone, marble, &c., will be arranged for the purpose of demonstrating the facility with which great masses of stone are transformed into useful and ornamental objects and made suitable for the most skilled handicraft.

Sands for the manufacture of glass, many coloured clays, and kaolin of all grades for the potter, brickmaker. porcelain worker, &c., polishing substances, whetstones, hones, and emeries, will be included, Asphalte and cement mixtures and artificial stones which are adapted for road-making will be illustrated in all the multifarious uses.

Adding to the colour, effect, and interest of the exhibit, will be variegated heaps of nitrates, sulphates, borates, pigments of all kinds, ochres and vermilions, phosphates, coprolites, and every variety of mineral fertilisers. In another group graphite, with the methods by which it is transformed for use in the shape of lead pencils, crayons, lubricants, &c., will be exposed.

Ingots, bars, and castings of white aluminium, with aluminium alloys, will be found in juxtaposition with pigs and bars of copper. Tin ores and block tin, sheet and bar zinc, ingots of nickel, specimens of bismuth, antimony, arsenic, and other minerals with their ores and alloys, will be systematically arranged.

In the Mining Machinery Section will be shown every species of apparatus, simple and complex, employed in working a mine from the lowest level to the dump. Methods of timbering, ventilating, and lighting the various slopes, levels, and galleries will be shown by examples. Trams, hoists, and automatic dumps, engines for pumping, rock breakers, screens, grizzlies, and other sizing appliances will be shown. Improved diamond drills, and contrivances for loading and unloading coal and ores, and for their storage; automatic stevedores for transference on the surface; patent self-emptying cars; wire ropeways with their outfits of buckets, &c., coal tips, steam shovels, belt conveyors, &c., will complete the methods by which the mining operations of the present age are conducted.

For the purpose of practical study, the historical division of mining and metallurgy will be provided. The literature, maps, models, &c., of the leading educational institutions of the United States will present to the student in this department, at the Columbian Exposition, an opportunity of reviewing the entire subject of historical and statistical mining. Mining engineering will be adequately represented by surveys and plottings, by projections of underground work and models, and by literature descriptive of the methods of running

shafts, tunnels, construction of mine workings and the handling of ores.

X.—The Transportation Building.

The Transportation Building, designed by Messrs. Adler and Sullivan, of Chicago, is one of the group in the northern part of the grounds. It is simple in architectural treatment, although it is intended to make the detail rich and elaborate. The style is somewhat Romanesque, and the good proportions, and subtle relations of the several parts to each other, suggest the methods of composition followed at the Ecole des Beaux Arts. Viewed from the lagoon, the cupola of the Transportation Building will form an effective feature south-west of the quadrangle, while from the cupola itself, a fine beautiful effect of the entire Exposition will be seen. The main entrance will consist of an immense single arch enriched with bas reliefs and mural paintings; the entire feature will form a rich and beautiful yet quiet colour climax, for it will be treated entirely in gold leaf, and will be called the golden door. The remainder of the architectural composition falls into a just relation of contrast with the highly wrought entrance, and is quiet, though very broad in treatment. It consists of a continuous arcade with subordinated colonnade and entablature. Numerous minor entrances are pierced in the walls, and with them are grouped terraces, seats, drinking fountains, and statues. The interior of the building is treated much after the manner of a Roman basilica, with broad nave and aisles. The roof is in three divisions; the middle one rising much higher than the others, and its walls are pierced to form a beautiful arcade clerestory. The cupola, placed exactly in the centre of the building, and rising 165 feet above the ground, will be reached by eight elevators, which will form a part of the Transportation Exhibit, and at the same time be used for the conveyance of visitors. The main building will have a length of 960 feet, and be 256 feet deep; in addition to this, there will be a series of annexes of one storey buildings about 60 feet wide. A complete system of railway tracks will be made in and about these buildings, and a transfer railway with tables 75 feet long, will run the entire length of the structure for the purpose of handling the heavier class of exhibits. It is intended that almost every object which will illustrate the work of transportation will be grouped within this building. The contents will naturally divide themselves into means of transportation by land and water, with an interesting, but less important, section devoted to aërostatics. It is desired to give to the collection a historic as well as a practical interest, and, for this purpose, examples of the earliest and crudest forms of transportation appliances are being sought for in all parts of the world. Marine transportation will have, of necessity, to be illustrated chiefly by models; and it is hoped that this country, which is so rich in this class of objects, will be induced to contribute largely. The wealth of ship models recently collected at the Naval Exhibition showed how easy it would be for England to add a supreme interest to the Marine Section of the Transportation Building, and how incomplete the exhibit will be without such co-operation. The English manufacturers of bicycles and tricycles will probably find it highly profitable to exhibit in this section, since the demand for these means of locomotion in the United States is very great, and is constantly increasing, while the reputation of our own makers is far ahead of that of any foreign manufacturers. Locomotives, rolling stock, and railway material, could, it would seem at first sight, not be exhibited with any view to commercial benefit, but, considering the crowds of American visitors who come to England every year, it is not impossible that the interest and curiosity excited by the exhibition of standard English trains would divert the flow of travel to the lines of those companies which had been sufficiently enterprising to make such a display. If this should be done, it would be advisable for railway companies to complete their exhibit by sending sections of permanent way, although the Chicago Executive will provide any possible facility for their convenience. In the building will also be exhibited railway signalling apparatus, a refinement of railroad working not so fully developed in the United States as it should be, and in this direction manufacturers of such appliances may find a profitable field. As far as possible all the exhibits will be arranged in groups relating to transportation in historical sequence, while preserving to a large extent a division by nations; in this way the interest of the collection will be largely increased without causing any inconvenience to the various foreign commissions.

XI.—Horticultural Building.

Opposite the wooded island in the lagoon, will be erected the Horticultural Building, a

great conservatory, 1,000 feet in length, and 287 feet in maximum width. The general features of this building are to be a central dome, 187 feet in diameter and 113 feet high. At each end is a large rectangular pavilion, and these wings are connected with the central rotunda by the main body of the building, each side of which is divided into two courts, 88 feet wide by 270 feet long. The courts facing the wooded island are constructed entirely of iron and glass, and will be used for especially tender plants. The rear courts, while they will receive abundance of light, are not entirely glazed; they will be specially adapted for fruit-growing exhibits, which may require a cool temperature. A large section of the courts will be devoted exclusively to the exhibition of orange culture in California and Florida. The central dome will be chiefly given to palms, bamboos, tree ferns, cacti, eucalyptus, &c. Ten miles of 1½-inch pipe will be required to heat the dome alone, and a still greater length will be wanted for the high temperature courts. The ground floor of each pavilion will be chiefly used for fruit exhibits, collections of seeds, and horticultural appliances. Broad galleries will run around these pavilions about twenty-five feet above the ground. The greater part of this area will be used for cafés and restaurants, and as the architectural treatment of the buildings includes an exterior arcade running around three sides—this arcade being extended to the upper storey in the pavilions—an additional amount of open-air space will thus be obtained, whence some of the most attractive views in the grounds will be seen. It is the intention of the chiefs of the horticultural department to encourage the best possible displays of all meritorious exhibits in the various groups of pomology, viticulture, floriculture, culinary vegetables, seeds, arboriculture, methods and appliances of horticulture, &c. As the available space is very limited, a careful selection will be made of the objects accepted. The classification of this department will embrace everything of professional interest to horticulturists, whether they are engaged on a large or a limited scale, and there can be little doubt but that the display will give us as great an impetus to the gardeners' art as did the similar but much more limited exhibit at the Centennial Exhibition of 1876. Already the applications for space in this conservatory from the United States alone, would fill the building several times over, and a system of the most rigid selection is therefore necessary. From Australia and New Zealand, from Latin America, and from China and Japan, applications are already arriving; the most curious exhibits from the last-named country will be the dwarf fruit and other trees, over a century old and not more than two feet high. Many of the States and territories have arranged to make a complete herbarium of their flora, and wax models of all their fruits; it is the intention of the chiefs of this department to make a great collective exhibit of these objects.

I think that there is every reason to suppose that this section will receive very warm and practical support from English horticulturists. Not only is our pre-eminence in the art fully recognised in the United States, but the importation of plants is not saddled with the heavy taxation that applies to most other objects to that country; in fact, all plants intended for indoor cultivation, for the production of cut flowers and for decorative purposes, are admitted free. In the same way many garden seeds are equally unencumbered, and, as will be seen from the following list of exports for 1890, a very large trade is done in them by seed producers in this country:—

UNTAXED EXPORTS.	Value.
Flower and other seeds	£67,000
Trees and plants	114,100
TAXED EXPORTS.	
Bulbs	73,730
Garden and agricultural seeds .	60,400
Plants, &c.	934,990

It will be within the remembrance of many persons who visited the Centennial Exhibition at Philadelphia in 1876, that the rhodedendron displays made by British growers gained the wonder and admiration of millions of American visirors; this exhibit laid the foundation for a large and constantly growing trade in this particular shrub, and I was recently informed by one of the chiefs of this department in Chicago—an eminent horticulturist—that, despite the advance that has been made in America in this branch of culture, we still maintain the lead that we had nearly twenty years ago. In 1876 there were less than a thousand nurserymen in the whole of the United States; this number has been increased more than fourfold at the present time, and the trade in America with cut flowers and decorative plants is enormous. At the beginning of this year there were 4,659 floriculture establishments in the United States, with nearly 39,000,000 square feet of glass. The

value of these establishments is about £8,000,000 sterling, while the value of the plant sales during 1890 amounted to £2,500,000 sterling, and that for cut flowers to nearly £3,000,000. With this very extensive business, with the acknowledged fact that we, as floriculturists, are far in advance of the United States, and with the very favourable conditions that exist, there is every reason to suppose that in this department, at least, British exhibitors may go to Chicago without the least doubt as to the commercial success of their undertaking.

Before dismissing the Horticultural Building, it may be added that extensive grounds will surround it; that these grounds will be laid out in the most elaborate manner, and be adapted for flower displays which will also form exhibits. The art of carpet bedding has been carried, according to our more sombre eastern ideas, to theatrical extravagance in the United States, and while one cannot but admire the ingenuity which tortures foliage plants and brilliant flowers into "Gates Ajar," terrestrial globes, canoes, sundials, and the like, the British landscape gardeners will probably be content with admiration, and refrain from imitating these curious triumphs of floral decoration.

XII.—The Womens' Building.

For the first time in the history of international exhibitions, a special building is to be devoted exclusively to the display of female art and industry. In order that this idea should be carried out thoroughly, it was decided a separate building should be set aside for the purpose, and that the pavilion itself should be the work of a lady architect. The building is in Italian renaissance, and covers a rectangular space 200 feet by 400 feet. The interior of this building, which will have spacious galleries running around the four sides at a height of about twenty-five feet above the ground, will be divided into a number of courts devoted to different sections of industry. Probably the most useful and interesting of these will be those relating to hospital work, rescue organisations, and the helping and care of children by systematic methods. The work of female painters will be for the most part shown in the Fine Arts Building, but is the hope of the committee—consisting, it is needless to say, wholly of ladies—to have a large and valuable art display in a hall that has been arranged for that purpose in the building. Mrs. Potter Palmer, one of the most prominent women in Chicago, is the president of the committee; she appears to have organised this part of the Exhibition with much ability, and during her visit to Europe last summer she did admirable work in exciting the attention and assistance of many public-spirited ladies in this country and on the continent. It is therefore probable that influential committees will be formed in various countries of Europe to co-operate with Mrs. Palmer, and that the display in this building at all events will be international in the widest sense of the word.

I have recently received from Mrs. Potter Palmer a somewhat detailed description of the women's exhibit scheme, and I present an abstract of it here because the project is novel, and will undoubtedly be of high importance. The Board of Lady Managers is the first official body composed of women ever recognised in a grand international enterprise, or endowed with executive powers equal to those bestowed by the liberality of the National Commission; it has also been given funds to execute these unprecedented powers thus bestowed.

"The last session of Congress appropriated for the use of the Women's Board 36,000 dollars for the fiscal year, and will ungrudgingly give as much more as it may ask or need. Indeed, a vote of thanks to the president of the Board and its finance committee at an ensuing meeting of the National Commission, cordially acknowledged their efficient assistance in securing the whole World's Fair appropriation from Congress.

"The Directory—the local portion of the Exposition—having in charge the preparation of the site and erection of the buildings, led the way in splendid generosity to the Woman's Board. It gave the Board first choice of a site, and a magnificent building costing 200,000 dollars. Moreover, the Board was given absolute freedom in the control of this grand structure. Designs were invited from women architects, and the result awaited in somewhat uncertain expectancy. Women were not known in this craft, and the President of the Board confessed an apprehensive sinking of the heart when summoned to assist the Chief of Construction in examining the plans submitted. There were thirteen of them; none were poor, whilst most were excellent, and the principal difficulty was to decide which was the best. Three of the designs were awarded prizes, and then—after the award was made—the interesting fact was disclosed that all the plans were the work of young girls, ranging in age from

twenty to twenty-two. Miss Sophia Hayden, of Boston, won the first prize, and was at once summoned to Chicago to perfect and elaborate the design.

"So much for the exterior of the Women's Building, which is more advanced in construction than any other of the Exposition structures, and which is now practically finished; the interior and contents may now be referred to. Members of the Board have offered contributions to the building, in the form of native materials, in the name of their respective States. The first offer of the kind came from Washington, the youngest State in the Union—Mrs. Houghton, its lady Manager, proffering a granite column. Montana asked permission to give the last nail to be driven in the Women's Building by the president of the Board, promising to make it of gold, silver, and copper, the richest metals of the State. Subsequently the officers of the Board of Lady Managers invited contributions of native materials from the different States, such as fine woods, stone, and marble. Fine woods will be profusely used; proffers of them come from every direction, and there will be much fine carving, which will all be done by women, a condition necessary to gain admission. The reception room will be wainscoted in light wood, and as the panels can be carved separately, the Board will furnish dimensions and also designs, if desired, to any one who wishes to carve a panel. There are also several fine surfaces for mural paintings, to be entrusted to artists of undoubted ability, and workers in metals will also find a fine field. In addition, every one, without discrimination, is invited to contribute whatever she may make, manufacture, or possess in rare, particularly beautiful, or artistic hangings; objects of this description will be returned at the close of the Exposition.

"Any woman exhibiting particular fine work under the general classification, will probably be invited to send something of equal excellence to the Women's Building. By this means, no woman need lose the privilege of appearing in the special exhibit of the Women's Building while exhibiting in the competitive departments of the main buildings.

"Women are given, by the Act of Congress and the generosity of the National Commission, representation upon all juries of award, upon work produced in whole or in part by female labour, the representation to be in accordance with the proportion of woman's work in each department of the classification. The Lady Managers realise that in the selection of these jurors lies a fair test of the fitness of women to be entrusted with an office of such consequence. It is fully aware that the critical eyes of the whole world are upon it; that to fail would be to set back the clock of time half a century for women, while to succeed opens for them a new area of civilisation. Accordingly, the Board will select its representatives with proportionate care and discrimination, searching the United States from the Atlantic to the Pacific, from Maine to Florida, for experts to place in nomination for appointment upon the different juries of awards.

"From its organisation, the Board of Lady Managers has been working ceaselessly, untiringly, and with important visible results in every State and Territory in the Union. It has, moreover, been able to extend its influence beyond the continent, and to enlist in its cause many of the most powerful men and women of Europe. The French Government has voted to appoint women representatives to co-operate with the Board of Lady Managers, and their names will soon be announced. Dutch Guiana has already appointed two women on her Commission. The prospect of recognition in France is excellent; and there is little reason to doubt that it will be accorded in the majority of instances. The women of France and England, and indeed of Europe generally, evince a marked tendency to give their attention chiefly to a showing of philanthropic enterprises, leaving the industrial displays to men, who will have sufficient commercial incentive, without other inducement, to make them. A similar inclination is observed in the work of the Board of the United States. The statistics gathered by its members in this energetic and unprecedentedly close scrutiny into women's work, have fixed startled attention upon certain distressing facts which must assuredly lead to an amelioration of conditions. This was notably true of the Hungarian women working in American mines, and of child labour in various portions of the United States. Powerful labour organisations throughout the country were in communication with the Board during its recent session, concerning the suppression of child labour, the proportion of women's work, &c.

"Particular prominence will be given to exhibits of a domestic, sanitary, educational, and philanthropic description, as representing

the subjects in which women are most deeply interested, and the fields in which they can make the most telling, impressive, and useful showing. The medical director of the Exposition has generously ceded women physicians equal recognition with men upon his staff in the Exposition hospital. This potential fact may be particularly mentioned as indicating the substantial and permanent nature of the Board's influence. The Women's Building will also contain a model hospital fully equipped with physicians and trained nurses, and in connection with it will be the Department of Public Comfort for the treatment of cases of slight indisposition and accidents incident to great crowds. By the courtesy of the Director-General, the Board of Lady Managers will be permitted to establish branch rooms of the Department of Public Comfort in all the main buildings of the Exposition. Without in the least encroaching upon the prerogative of the general hospital, these branches of the Department of Public Comfort will greatly relieve the pressure upon it, and incalculably promote the general welfare.

"The preliminary work in most of the States tended chiefly to securing favourable legislation, towards influencing a liberal appropriation, and official recognition of women upon the State Commissions. Illinois has set a splendid example by placing ten per cent. of her entire appropriation of 800,000 dollars at the absolute disposal of a State Board composed of women. A large proportion of the twenty-eight States which have made World's Fair appropriations and have appointed State Commissions, have given women representation in the same. In a nnmber of States women have taken the initiative in rousing enthusiasm for the Exposition. In various sections the Lady Managers have inaugurated a careful search for the native flora, thus giving valuable assistance to the Chief of Horticulture in making a collection of the plants, fibrous, edible, and medicinal, indigenous to the United States, of a completeness never previously attempted, which will doubtless prove to be a marked feature of the Exposition, and of great permanent value to science.

"A committee was appointed during the September meeting of the Board to formulate a general plan of State work, and to issue printed suggestions for general distribution. One of these pamphlets is now in circulation, and others will rapidly follow. Many helpful hints were mutually exchanged during the reading of the reports of State work at the last session of the Board, and much information pertaining to women's pursuits disseminated. One member explained that the chief difficulty in the way of successful silk culture, an industry in which women are largely interested both industrially and financially, was the imperfection of the reel; and that the best reels now in use were those of home manufacture made by rustic artisans under the direction of Italian women, who are expert in the reeling of silk. Mention was also made of the inauguration of flower farming in South Carolina. This is a new industry in Ameriea, and similar in character to that of Southern France, the flowers being used in the manufacture of extracts, perfumes, and pomades, and the growing of them promises to furnish a profitable, pleasant, and healthful occupation to women.

"America has never made an exhibition at all commensurate with her unparallelled resources, her unequalled extent, and the infinite variety of her climate and products. Perhaps it will not be asserting too much to say that the United States has never made a single or collective exhibit of which there was any sufficient reason to be proud. Nor have the women of the Union ever before been given any very considerable part in the making of a similar enterprise. Now that a progressive Congress and a liberal National Commission, and a generous Directory have placed almost unlimited power in the hands of American women, the Board of Lady Managers, representing every section of the country, are resolved to aid in rendering the World's Columbian Exposition the most magnificent achievement in the history of the Great Republic."

I have devoted so much space to this description of the women's exhibit because it is authoritative, and shows how much in earnest the women of America are upon the subject.

XIII.—Fine Arts Building.

The Fine Arts Building will occupy a site on the north side of the small lake at the northern end of Jackson-park. It will without doubt be one of the most successful pieces of architectural design among all the great and elaborate buildings that constitute the Exhibition. A pure style of Grecian Ionic has been followed throughout; the plan is rectangular, and the building is 500 feet long by

320 feet wide. The rectangle is divided in four large courts by a central nave and transept, which are 100 feet in width and 70 feet in height; at the intersection of these galleries a dome will be constructed about 90 feet in diameter, and occupying the centre of the building. The height to the top of this dome will be 125 feet, and it will be surmounted by a group of colossal figures. The plan of the building thus divided by the nave and transept, will leave four large galleries about 200 feet in length and about 110 feet wide, and a number of smaller courts; these will be reserved entirely for the exhibition of paintings. One court will be occupied by the United States and one has been allotted to this country; the other two are to be given to France and Germany. The clear width of the nave and transept will be 60 feet, as galleries 20 feet in width and 24 feet above the ground will be constructed on either side; the ground floor of the main passages will be devoted to sculpture, and the walls at this level, as well as that of the galleries, will be utilised for mural paintings and sculptured reliefs; space will also be found near the dome for several small picture galleries. Running around the exterior of the building will be galleries 40 feet in width, which will form a continuous colonnaded promenade. The interior will be lighted throughout by skylights, and it should be mentioned that the various courts will be completed ready for hanging pictures, all necessary decoration and shading being provided by the Exhibition authorities. There will be four main entrances to this Art Building, each entrance being so treated as to add to the architectural effect of the structure; the floor level is fixed at such a height as to allow of the introduction of a broad flight of steps at each entrance. The wall of the colonnade running round the building will be decorated with mural paintings that will constitute exhibits, and the exterior frieze as well as the main entrances are ornamented with sculpture and portraits in *bas-relief* of the old masters.

The greatest care has been exercised by Mr. Burnham, the Chief of Construction, in making this building fire proof. No woodwork, excepting that of the panellings and internal fittings of the courts, will be exposed. The framework upon which the architectural effects will be carried, is of course of timber; but this will be so completely embedded in the cement that forms the exterior walls, that no danger need be apprehended. The structure itself is essentially a piece of engineering work; all the main walls are of brick, and the roof, galleries, floor, and dome are of steel; the floors will consist of brick arches turned between the steel girders. In fact, although this building is unfortunately to be temporary like all the others in Jackson-park, as much care is being taken in the construction as will be exercised in building the permanent Art Palace which is to grace the lake front park and constitute the future art museum of Chicago.

The Fine Art Palace is beautifully situated with its south front facing the small lake above mentioned; it will be separated from this by balustrated terraces, and a monumental stairway will lead to the water level and to boat landings that will be constructed there. The north front of the building will face an extensive lawn, beyond which will be the group of State buildings. To the east and west of the main building are to be constructed some one-storied annexes, which will also contain picture galleries. The design of these isolated structnres, which are to be 200 feet long and 120 feet wide, will harmonise with that of the Fine Art Palace. The ground in the immediate neighbourhood of the Art section will be ornamented with groups of statuary, chiefly reproductions from classic and from modern art. The estimated cost of the main building is £120,000; the architect is Mr. P. B. Attwood; the annexes are to be built from designs that were prepared by the late consulting architect to the Exhibition, Mr. George W. Root, whose unexpected and untimely death left a gap in the executive ranks which it was impossible to fill.

XIV.—States and Foreign Official Buildings.

The north side of Jackson-park—that which had been already reclaimed and planted by the Park Commissioners—has been set aside for the use of the various States of the Union which will require separate pavilions in addition to the space which will be allotted to them within the main buildings. If, as is expected, all of the States avail themselves of the facilities thus afforded, there will be forty-eight of these pavilions, each of which, besides containing a certain number of special exhibits, will serve as offices and club-rooms for the State to which it belongs. Already a majority of States has voted considerable sums for Exhibition purposes, and many of the structures will be on a large scale and very elaborate.

The pavilion of the State of Illinois is not included in this group; as the State in which Chicago is situated, it possesses special claims and responsibilities—the claim of occupying a conspicuous position, and the responsibility of making a larger grant than would otherwise have been expected. This she has done, and the advantage of a distinctive site has been accorded by the Exposition authorities. The Illinois building will face the Fine Arts Hall, being separated from it by a small lake. The building will be 160 feet wide, and 450 feet long. Excepting for a space at one end, 75 feet by 60 feet, which will be reserved for a model school house, the interior will present an unbroken rectangular hall, in which the State exhibit will be collected; a memorial hall on one side, and a spacious vestibule on the other, will form wings to the main structure. The architecture is Italian Renaissance, and the principal feature will be a central dome 72 feet in diameter, and about 200 feet high. It will be at once seen that this building will be of quite imposing dimensions, and none of the other States are likely to have so important a pavilion. The whole group of State buildings and their contents, so far as they are open to the public, will be of much interest.

To the south-east of this part of the park is the area set aside for foreign official pavilions. It is pleasant to know that the best location on the ground has been reserved to Great Britain—that on the lake front close by the model battleship. Immediately behind this is the Mexican allotment, and a little to the north is that given to Germany; at the present time no further demands have been made for this space, which, however, will doubtless be filled up before long. The Royal Commission hopes to be able to erect on their land a pavilion that shall be appropriate to the location and worthy of the occasion.

XV.—The United States Government Exhibit.

The present money grant of the Government for the official exhibit is 1,500,000 dollars; of this £80,000 is to be devoted to a pavilion and the remainder distributed in varying sums to the different departments, which will have between them 200,000 square feet of floor space. This does not include the exhibit of the Navy Department, which will be contained in a full-sized reproduction of one of the latest American battleships. The Government building will be a large and imposing structure, upon which, however, no money will be wasted in superfluous decoration; it will be rectangular in plan, 420 feet long on the principal front facing the lake, and 320 feet deep; in the centre will be an eight-sided dome, 120 feet span, and around it will be grouped the spaces for eight Government departments. The State Department will occupy a long gallery, 40 feet wide, leading from the main entrance to the dome, and the Department of Justice is allotted a similar gallery on the other side. On the right hand of the main entrance is the Fisheries Section, 100 feet wide by about 190 feet long, and a similar space on the left hand will be divided between the Post Office and Treasury Departments. In the centre will be the Smithsonian Institute and the Department of Agriculture, and at the back of the building similar spaces will be given to the Department of the Interior and to the War Department; each of these sections will have a floor space of about 125 feet by 175 feet.

XVI.—The United States Navy Exhibit.

The exhibits of all the United States Government departments, with the exception of that of the Marine, will, as just stated, be contained in the public building already referred to, or in annexes built on the adjacent ground, which, it may be mentioned in passing, will also be made use of for various military displays during the course of the Exhibition. The Navy Department, however, has conceived, and is carrying out, an entirely novel scheme, which will undoubtedly prove a great attraction to a large section of the American people who have never visited the eastern or western seaboard of the United States. This is no less than the construction, in the lake, of a full-sized model of a line of battleship; a sister vessel to the *Indiana*, *Massachusetts*, and *Oregon*, which were designed at the Naval Bureau of Construction, and are being built, two by Messrs. Cramp and Sons, of Philadelphia, and the third at San Francisco. An especially interesting feature of the exhibit is, that the model will be built on a submerged platform in the lake, so that from the water line to the tops, it will present in every detail the actual semblance of an armour-clad ship of war. The site selected for this exhibit is shown upon the plan, and you will observe that it is protected by breakwaters against the lake storms, and is situated immediately to the south of the site on which will be erected the British Administration Building, which can repose peacefully under the protection of the wooden guns of this

battleship. The model will be 348 feet long upon the water line, 69 feet 3 inches wide amidships, and it will have 14 feet of freeboard. The hull of the vessel from the submerged platform to the main deck will be built of brick and concrete, finished outside and inside with cement moulded to the contour of the vessel. Beneath the water line an apron of moulded iron plates will extend to shield the platform, so that under no circumstances will the semblance of reality be destroyed. Upon the main deck will be built two armour-plated redoubts, 34 feet 6 inches in diameter, and in each of these will be mounted two 13-inch breech-loading guns. These guns, as well as the redoubts, are built up of a wood framing, finished with cement; the guns, however, will be fitted with a steel rifled tube and breech mechanism, while the carriages on which they are mounted will be so real that all the evolutions of loading and training can be performed. In the same way the mechanism for revolving the turret, handling ammunition, &c., will be capable of being worked. On the upper deck there will be eight 8-inch guns, also mounted in turrets or redoubts, and a battery of Hotchkiss guns will be furnished. The armament will comprise in addition, four 6-inch rifled guns, which are mounted on sponsons built out from the side of the ship; twenty 6-pounder quick-firing guns; six 1-pounder quick-firing guns; two gatlings, and six torpedo tubes. The whole of this minor armament will be real, and the guns will be furnished by the Naval Gun Factory, with carriages, shields, and all equipments in complete working order. An iron military tower will be built at the forward part of the upper deck, and above will be the military tops in which some of the quick-firing guns will be mounted. The conning tower will also be shown completely fitted with all the electrical and other appliances required by the commander in time of action. The bridge, which extends along the whole length of the vessel, carries a number of Hotchkiss guns and the chart-house; on each side of this bridge the boats are hung, and these, together with the cranes, davits, and appliances for working them, will all be actual, so as to form real and working exhibits. Torpedo spars will be fitted to the sides of the ship, so that the operations of manipulating the torpedo netting can be exhibited. A large electric-light plant will be fitted up on board to illustrate the various uses of electric light on board ship. Current will be furnished from the power station of the Exhibition. The quarters for officers and men will be in all respects an exact reproduction of the actual accommodation on these ships; and during the time of the Exhibition the vessel will be manned completely, and, so far as is possible, all the evolutions on board a man of war will be regularly carried out. The remainder of the Navy exhibit will be completed by the engineering department, and the Government will erect on the ground near the vessel one of the great marine engines which is placed in this type of battleship, complete with boilers, shaft, and propeller; the whole of this installation will be kept in motion. The Gun Factory will have a pavilion close by, where heavy guns, armour plates, projectiles, &c., will be exhibited. The Naval Observatory will also put up a building, in which will be shown a large number of scientific instruments belonging to this section of the department. One interesting object in this building is to show the method in official use for transmitting exact time all over the United States, and it will form a central station to a large and complicated system over the whole of the Exhibition grounds. In accordance with an old treaty between this country and the United States, neither Power is at liberty to have more than one ship of war cruising upon the lakes. This section of the American Navy is represented by the entirely obsolete but very hospitable and festive steamer, *Michigan;* while the flag of Great Britain flies over an equally ancient craft. It is proposed, however, with the consent of this country, that this treaty shall be held in suspense during the term of the Exhibition, in order that a number of torpedo boats, and other small war vessels, may be brought to Chicago to illustrate in some degree the new and powerful Navy of which the United States may be so justly proud. The estimated cost of this vessel, which will be called the *Illinois*, is £20,000; it was designed by Mr. Frank W. Grogan under the direction of Captain R. W. Meade, who is the chief of the Navy Department at the Exhibition.

XVII.—The Fisheries Building.

This building will be devoted to fishery exhibits, and its dimensions will be such as to enable a very imposing display to be made. The length of the building will be 1,100 feet, and the width 200 feet; in addition to this there will be two annexes, connected with the main building on each side by arcades. The arrangement for thus dividing the building,

instead of grouping all the exhibits under one roof, was rendered necessary from the form of the ground chosen for the site, the surface of which could not readily be levelled over the whole area. The main building will contain the general fisheries exhibits. The centre will be occupied by a large tank, which will contain a great variety of fish, shells, and marine growths, so arranged as to make it a specially attractive object; in the centre will be a fountain. The exhibit will be arranged around the tank on the ground floor, and in suitable galleries in the upper stories. Other large ponds will be constructed in connection with the building in which specimens of the larger fish, such as sharks, sword-fish, &c., are to be induced if possible to disport themselves. One of the annexes will be devoted to angling exhibits, and the other to an aquarium, which is to be partly underground, and to be on an unusually large scale. The architecture of the building is "Spanish Romanesque," and considerable hardihood and ingenuity has been shown by the designer in combining elaborate decoration in the capitals, medallions, &c., in which fish are introduced as the leading feature. The design is certainly a pleasing and an ornamental one, and the effect of the materials imitated—dark brown stone for the walls, and old Spanish tiles for the high roof—ought to be excellent. The architect is Mr. H. Ives Cobb, and the cost is estimated at £75,000. Judging from the wonderful advances that have been made in all matters relating to fish culture, and the capture and utilisation of fish in the United States, this section of the Exhibition will be of high interest. The Fish Commission will show a separate collection in the Government Building.

XVIII.—The Midway Plaisance.

The Midway Plaisance is a strip of ground about 600 feet in width and a mile in length, that connects Jackson with Washington-park. The junction with the former is at the point shown on the plan, immediately opposite the Women's Building. This extensive piece of land, at present almost waste, is to be converted to various uses that may perhaps be best described as a Street of Nations. Here will be collected all, or nearly all, of the Auxiliary Exhibitions, to which admittance will be gained by extra payment—theatres, panoramas, Oriental amusements, and the like. It is to be a Bazaar of all Nations, for it is only in this part of the Exposition that current sales will be allowed. Native villages from various civilised and uncivilised parts of the world will be organised, to gratify the curious, or instruct the student; refreshment booths and beer gardens will not be wanting, and probably more than one of those ingenious reproductions, initiated some years ago by the inventor of Old London, and since so often and so successfully repeated, will find a profitable if short existence on the Midway Plaisance. There is little doubt that this portion of the Exhibition will always be crowded, just as the famous Rue de Caire at Paris, in 1889, was usually impassable. But this Bazaar of all Nations will be on a much larger scale than the Rue de Caire, and a railway running down the whole length will be a necessity. The concession for this railway has been granted to the proprietors of the sliding water railway that attracted so much attention in Paris, and no doubt a proportionate degree of success is awaiting it in Chicago. Already a considerable amount of space has been allotted in the Midway Plaisance, and no time should be lost by those who wish to avail themselves of the opportunity it affords being present. I am informed that already concessions for twenty panoramas have been granted. It is at the junction of the Midway Plaisance with Jackson-park that the great Columbian Tower is to be erected. Of course this tower is to be higher than that of Eiffel, it would not otherwise be worthy of the occasion or of Chicago; it will be 1,120 feet in height, and from its summit the visitor will be able to see the city limits of Chicago. That it is the work of a well known American engineer—Mr. George S. Morison, is a sufficient guarantee of its stability, though probably the foundations will be a far more difficult matter than those of Paris. It is said that Mr. Carnegie, the famous American steel maker and capitalist, is at the back of this enterprise, for the completion of which there does not seem very much time.

XIX.—The Pier.

From the southern side of the Grand Avenue a pier has been constructed extending into the lake for a distance of 180 feet, where it terminates in extensions to the right and left of about the same length; the outer side of this pier head is protected against the lake storms by a breakwater, and on the north side another breakwater with sufficient openings will be constructed from the pier head to the shore, forming an enclosure 1,800 feet long and about

1,000 feet wide. This large water area will be utilised for the smaller floating exhibits, and as it will be entirely protected it will doubtless be a favourite place for boating and other aquatic amusements. The pier will serve as a landing place for the extensive fleet of fast passenger steamers, which will be the pleasantest means of transport between the city and Jackson-park in favourable weather. It will also serve for the convenience of visitors making use of the fast electric launches which are to ply for hire about the harbour, through the great basin and in the canals. It is expected that these launches will be a very useful means of circulation in the grounds, and they will accordingly be provided in very considerable numbers, and landing stairs will be constructed at convenient places. Probably the fleet which Columbus navigated across the Atlantic 400 years before, and which is now being reconstructed as nearly as historical data permit, will be moored in or near the harbour. It was intended that at the shore end of the Grand Avenue the basin should terminate in a semicircular embankment with wide waterways, affording ample communication between the harbour and the canal system in the grounds; around the outer edge of this semicircle was to be placed a row of thirteen columns, each surmounted by the device of one of the thirteen original States of the Union. Rising from the water in the basin will be a colossal statue of Liberty; this statue is being designed by Augustus St. Gaudens, of Paris. At the pier head was to have been built a casino containing a restaurant and music-hall. It is probable that this part of the scheme will be modified, and that the most of the pier head will be utilised for restaurants. Certainly the most attractive view of the Exhibition will be obtained from this spot. Looking shoreward across the blue water of the harbour, full of colour and animation from the numerous and varied craft which will be moving on its waters, the visitor will see before him the whole extent of the Grand Avenue and the beautiful façades facing it; on his right will be the long front of the Industrial Building, thrown into relief by a series of small and elegantly-designed cafés that will stand between it and the lake; beyond will be a view of the Government reservation, with its encamped soldiers and many suggestions of the United States army; the great model of the battleship will be full in view, and beyond the perspective will be closed in by distant glimpses of some of the larger buildings and the confused picturesqueness of foreign administrative buildings and the pavilions of the various States. To the left the Exhibition will offer but little that will be attractive, the ground south of the pier being occupied almost wholly by the agricultural exhibit. There will, however be one notable exception to relieve the poverty of this portion of the view. On a tongue of rising ground projecting into the lake will be built a copy of the Convent of La Robida at Palos, so closely associated with the history of Christopher Columbus.

During the last few weeks an important alteration has been made in the design of the Exhibition, so far as concerns that part of it on the eastern end of the Grand Avenue adjoining the pier. The original design has just been referred to: a casino at the end of the pier, and the semicircular mole, surmounted by thirteen columns, at the shore end of the Grand Avenue. Both these features are to be abandoned, and the money which was to be spent upon them—£41,000—is to be devoted, to two buildings, each 140 feet by 200 feet, on the north and south side of the basin; these will be connected by a colonnade, 60 feet wide and 500 feet in length, something like that leading to St. Peter's at Rome. One feature of the colonnade will be the introduction of 48 columns, representing all the States and Territories. Where the colonnade crosses the basin, this latter will be spanned by a high and wide arch, giving free access from the harbour to the canal system of the grounds. One of the new buildings—that at the northern end—will be used as a music-hall, and sitting accommodation will be provided for 2,000 people, with an orchestra of 75 instruments and a chorus of 300 performers; there will also be a hall for rehearsals, to accommodate 600 people. The music-hall is not intended so much for popular concerts as for select performances, and it will probably be in this building that the Musical Congress, the general outline of which has lately been announced, will be held. The building at the south end of the colonnade will serve as a restaurant. In the south end of the park will be provided accommodation for the more general musical entertainments, such as grand choruses, grand concerts, and band concerts. In a special building accommodation will be provided for 15,000 persons. This structure will be known as the Live Stock Amphitheatre or Show Ring; it will be situated in the Agricultural section of the grounds, and be used for the above-named purpose after the series of projected musical entertainments

has been completed. There can be no doubt as to the improvement that will result from this alteration; the pier head will certainly be a favourite place of popular resort, and restaurants will probably be found there. Mr. Attwood, the architect of the Fine Arts Building, has designed these alterations.

XX.—The Department of Decoration.

Some reference should be made to the method which has been adopted for insuring harmony of decoration throughout the entire Exhibition; this has been done by creating a Department of Colour under the charge of an experienced artist, whose duty it is to superintend, not only the whole of the constructive ornamental work, but also to decide upon the colours which shall be used in the decoration of each building, with proper regard to the effect produced on the building itself, and the part it has to play in the general scheme. This novel and responsible position is filled by an Englishman, Mr. William Prettyman, who is ably sustaining the reputation of his country in the decorative arts. The post is a very onerous one, as the purely artistic part of the work forms only a small portion of Mr. Prettyman's duties. He has under his charge the very extensive art studios at Jackson-park, where workmen of all nationalities are engaged in modelling the reliefs and other decorations, which will be employed in such large quantities upon the buildings; moulds in elastic composition are taken of these models, and in them are cast the reliefs in cement. As there will be an enormous amount of mural painting, mosaic pavement, internal decoration, and later on, all the rich effects to be produced by flags and other vehicles of colour, it will readily be imagined that the post is no sinecure.

A few days ago I received from Mr. Prettyman a description of the general plan of decoration he has composed for the Exhibition Building, and as this is of considerable interest, a short notice of it is given in this place. The great buildings surrounding the Grand Avenue will be of one tone, that of yellow, approximating to old alabaster, the surface of which has begun to disintigrate. On approaching the informal lines of the lagoon and wooded island to the north, the buildings are cut off from the Grand Avenue by another scheme of colour. The Transportation Building will be painted with the colours of Spain, which was the first country to provide means of transport to the New World; the tones will be gold, yellow, and red, but not so brilliant as those of the national colours. The Horticultural Building comes next; this will be a mass of glass, and the walls will be tinted ivory colour, warmed with a slight rose tint. The Women's Building will be of a yellow ivory tone, blended with a very delicate orange, and the roof will be red, making a contrast to the roofs of larger buildings, which are of a *vert-de-gris* colour, like old copper bronze. The Fine Arts Building being purely classic, and reflecting the architectural motives of the buildings in the Grand Avenue, will be of the same tint as those buildings; the dome will be covered with tiles of torquoise blue. The Fisheries Buildings will be coloured outside in a manner corresponding to the interior colouring of the Cordova Cathedral; the archivolts will be picked out in red blocks on a dull buff ground; the roofs of this building will be of marine blue. Returning to the Industrial Building, there will be eight grand entrances; four of which will be decorated with sculpture, while four will have mural paintings, suggesting the contents of the buildings. Large panels will be placed in the timpani of the arches over these entrances; they are segments of a circle 30 feet in diameter. The interior of this building will be so vast, that beyond a certain height it is not probable that any attempt will be made to decorate the great space over head, excepting to paint it of a light tone, which will serve to reflect the electric light in at night. A good eye line will be taken, such as gallery fronts, and these will be treated with a good deal of modelled work sufficiently strong in colour to give animation, while broad gold and coloured lines will be placed on the lower portion of the roof. This plan will be carried out in most of the large interiors. Special decoration will be concentrated at certain points of the exterior of other buildings; thus the main entrance to the Agricultural Hall will be formed by a temple of Ceres; in the centre will be a statue of Ceres, surrounded by a colonnade and domed roof, all of which will be richly expressed in gold and colour, and there will be a mosaic floor in black and white to emphasise the Ionic character of the building. The entrance to the Mines Building will be of marble and mosaic, the decorations being in gold, silver, and black, colours emblatical of mineral products. The grand entrance to the Electricity Building will be a magnificent hemicycle, which is to be made as brilliant as possible for night effect, by the use of porphyry

columns, and great masses of gilt modelled work in relief; a gigantic statute of Benjamin Franklin will stand in the centre of this entrance. Little or no decoration will be given to the Machinery Hall, the idea being that its appearance should harmonise with its contents. The main entrance to the Transportation Building will be a great arched doorway, covered entirely with gold, intensified by strong reds and blues. The interior will be very simply treated with elementary byzantine decoration. The Fine Arts gallery, which will have a mile of hanging space on the walls, will have little internal decoration; the hanging spaces will be of the usual dull red found most suitable for the purpose. But at the entrance and under the central dome, gold, colour, and decorative figure work will be freely used. As for the Administration Building, its roof will be covered with aluminium bronze highly burnished, and its decorative scheme is that of a monument to great discoverers. Outside there will be eight large inscriptions, detailing facts in the life of Columbus, and forty names of discoverers of continents, or portions of continents. Inside there will be eight records of important discoveries in science, and as many names of great men of science. The dome will be lined with suggestive *bas-reliefs*, and the whole effect of the interior is to be simple, grand, and dignified. The internal decoration will consist of *bas-relief*, forcing the colonnade into view by flat panels, and the relief that gold will give to certain strong construction lines.

XXI.—The Exhibition Grounds.

Allowing for the 150 acres of main buildings upon Jackson-park, and for the large number of smaller and independent pavilions that will be erected there, there will still remain an area of about 400 acres within the park limits. A small portion at the northern end has already been reclaimed and laid out by the Park Commissioners; the remainder is a work that has yet to be completed, and this is in the hands of the famous American landscape gardeners—Messrs. Olmstead and Codman, who are widely known by their successful treatment of Central-park of New York, the Buffalo-park at Buffalo, and many others. In the arrangements of Jackson-park a considerable space will, as we have seen, be occupied by water—by the great basin, the canal, and the lagoons. The banks of all these will be either sloped or terraced, and marked by very numerous landing stages for the fleet of electric and other boats. Many miles of walks will be laid out in the park, the main thoroughfares being paved by artificial stone blocks, the exact nature of which has not yet been decided upon. At the present time, of course, all is chaos in the park, but before long the partial restoration of the surface soil, stripped for levelling purposes, will have to be commenced, and the planting of trees, which will be done with a liberal hand and with a view to the best effects, will be started. Enough excavated material from the basin and canals will be at hand to change the dead level of the ground as may be required, and in due time the lawns and flower beds will be formed. Much attention to effect will be concentrated on the terraces bordering the great basin, but the chief work of the landscape gardeners will be concentrated on the wooded island, a large area of land in the lagoon opposite the Horticultural Building. This spot, on which there already exists a certain number of trees, will be liberally planted with specimens of every suitable tree indigineous to the United States, while the ground will also be planted with azalias, rhodedendrons, and other flowering and decorative shrubs. There is no fear that the Exhibition Buildings will not receive a suitable setting, while beyond the busy and motley throng of all nations, the visitor seeking quiet and repose will find these in the wooded glades, and beside the clear waters of the lakes in Washington-park.

XXII.—The Exhibition of Relics of Columbus.

Mention has been made in another part of this paper of the reproduction of the Convent of La Robida, which is to be constructed on an elevated tongue of land projecting into the lake to the south of the pier; it was in this convent that Columbus found long and frequent intervals of rest and shelter. It is a part of the Exhibition scheme to do all possible honour to the memory of the great explorer, whose four hundredth anniversary is to be celebrated, and to make as complete a collection of the relics of Columbus as time, money, and labour, will permit. The work is, I believe, chiefly if not wholly in the hands of the Government, at all events it comes into the Latin-American Department of the Exhibition, and is placed under the control of a Government official, Mr. W. E. Curtis. The project is a very comprehensive one, and I am enabled to give a somewhat detailed account of it, which I do with much pleasure, because it will be found of interest, and because it

may be the means of inducing those who may be possessed of Columbus relics to lend them for the enrichment of the collection. The first part of this historical exhibit will include maps, models and *fac-similes*, intended to illustrate the condition of navigation and the knowledge of geography before and during the time of Columbus. This section will also comprise such evidence as is available of the discoveries that are alleged to have been made at an earlier period, whether by the Scandinavians, Danes, Welsh, Irish and other nationalities. Here the famous Leif Erikson will be thrown into relief; his statue will form part of the exhibit, and near it, maps and charts of his alleged voyages, and the settlements which it is claimed he made in Greenland; the localities associated with his name will be shown by photographs, and there will be a number of models of the Norse ships of his period. There will be a very fine collection of navigating and other nautical instruments in use before and during the time of Columbus, and the department is now trying to induce the Danish Government to send over, as a part of its exhibit, the original sagas of the Norsemen; there is a good chance of this being done. Finally, in this historical section there will be a large and very interesting collection of charts, including all the known ancient maps, either the originals or copies, from the earliest representation of the earth by the Hindus, to the globe of Martin Boreheim at Nuremburg; probably the original of this latter which exists in the Town-hall of Nuremburg will be lent.

The life history of Columbus follows this more general section. This collection will include illustrations of the various cities that claim him as their son—Cogoletto, Quinto, Genoa, and others; models of all the houses in which he was supposed to be born will be given; there will be photographs of the University of Pavia, where it is stated that he was educated; his life in Portugal and in Madeira is followed step by step, until he became associated with Spain, and in this connection photographic and other views will be shown of all towns and buildings with which his name can be linked. This stage of the story includes the Convent of La Robida, in Palos, which is to form the casket in which so many priceless gems are to be enshrined. As you are aware, Palos is a little seaport in the Spanish province of Andalusia; it faces the Atlantic, and it was from Palos that Columbus started on his first voyage on the 3rd of August, 1492. An extensive picture gallery will next attract attention; in it will be arranged all the paintings—either originals or copies in which Columbus figures, and as these are very numerous, and the subjects very varied, they will present an almost continuous, though, perhaps, not harmonious, life story of the great voyager. A separate room of this gallery will contain all the alleged portraits of Columbus that can be collected and which have any artistic merit; already forty-five of these portraits have been brought together, and it is probable that the student of the really remarkable series will be sorely puzzled to know what manner of man the discoverer of America was. Supplementary to the Columbus picture gallery will be another referring to the court of Ferdinand and Isabella at the time of Columbus, with a large collection of historical portraits.

Probably the interest in the collection will centre in the model of the *Santa Maria*, the caravel in which Columbus sailed from Palos on his first voyage. The *Santa Maria*, as well as her consorts—the *Pinta* and the *Nina*—were small and ill-found ships, actual particulars of which either do not exist or have not been discovered. We may, however, expect that much more will be known about them before long, as an officer of the United States Navy has been instructed to obtain full information, and afterwards to reconstruct a correct model of the *Santa Maria*. Lieut. Little, who was told off for this pleasant task, has, I presume, succeeded, for I am informed that he is now in Spain, where he is occupied in building the caravel; should time and funds permit, both the *Pinta* and the *Nina* will also be reconstructed, and this copy of the famous old-world fleet will be navigated across the Atlantic. It is intended that this ship, or the whole fleet if it is built, shall take a part in the great Naval Review which is to be held in New York Harbour in 1893, and to which all the maritime governments of the world have been invited to send their ships. The *Santa Maria*, on that occasion, and afterwards during the term of the Exhibition, will be manned by Spanish sailors in the costume of the time, and she will be rigged and equipped as nearly as possible (except, we presume, as concerns rations) as she was during her first voyage. After the Naval Review the caravel will be taken through the canals and lakes to Chicago, where it will be anchored beneath the walls of the Convent of La Robida during the period of the Exhibition.

Fac-similes of all the busts, monuments, and statues of Columbus that are known throughout the world are to be reproduced and shown, as well as models of his two burial places in San Domingo and Havana; as the first named place possesses a casket containing his alleged bones (which will also be represented), it may possibly have the greater claims to the privilege.

Thus it will be seen that it is the intention of the Latin-American Department to present a complete life-interest of Columbus, so complete indeed that it would probably astonish the great Admiral with many of its details. It is pretty certain that after so much painstaking investigation, the history of Columbus will have to be re-written.

Following these more showy and attractive exhibits, will come the section of bibliography, which will illustrate by what means a knowledge of his discoveries was communicated to the world. The geographical results of his voyages will be shown by a collection of maps and charts, from the earliest sketches down to the political divisions and the topography of North and South America of to-day. Exhibits to elucidate the reasons that gave America its name will be presented. Amongst other objects in this class will be a copy of the first edition of the *Cosmographiæ Introductio*, published at St. Die, and to which the continents of the new world owe their name. This famous book will be placed in a glass case in the centre of a room, and around it will be arranged a collection of illustrations of the place where the book was printed, with portraits of the authors and publishers, and of the patrons under whose auspices it was produced. I believe that Mr. Curtis is very proud of this collection, which is remarkably complete, a success due, so he informs me, to a series of fortunate accidents. With relics and records of Americus Vespucci and other early travellers, the personal part of the exhibit is completed, and the continent of America is taken in hand. There will be a great relief map of the two continents, on which will be laid down the various routes of Columbus, and the different places visited by him will be marked. To give increased interest to this part of the exhibit, photographers were dispatched from Washington to such places, and a large number of views are being taken that will illustrate the present condition of every spot he is known to have visited, including the West Indies, the north coast of South America, &c. By ethnological and archæological collections the conditions of the natives of these various countries will be indicated, as well as the impressions received about them in Europe from the early voyagers' reports and travellers' tales. This section will be enriched by drawings and descriptions copied from De Bry, Philipono, and other imaginative writers of the time who published fantastic representations of the original inhabitants of the continent.

Relics—that is, personal relics—of Columbus will be plentifully displayed. The ruins that marked the site of Isabella, the first settlement of the New World, have been acquired and are to be re-erected. An authentic anchor, and a cannon that he left behind him at Navidad, where he built a stockade from the wreckage of the *Santa Maria*, and the actual bell that was hung in the church tower of Isabella, and for the first time rung out on the breezes of the western world the tidings of a new religion, and of new phases of cruelty and persecution. These interesting mementoes are already in the possession of the department, and it is expected that many more will be acquired or lent, especially by the Spanish Government and by private collectors.

Finally will come illustrations of the conquest of Mexico and of the Colonial period, both treated in the same broad and complete manner; the former is divided into three epochs. First is the epoch of the conquest of Mexico; this will comprise (*a*) the civilisation of the Aztecs, illustrated by actual collections, by models, and by photographs. (*b*) The Conquistadores: Cortez is the hero of this section of course, and a large and very interesting museum of relics of that great adventurer will be arranged. (*c*) The epoch of the Conquest of Peru: this will include subjects to illustrate the civilisation of the Incas and the career of Pizzaro and his followers. Authentic relics of this period are quite numerous; the sword of Pizzaro is in the Royal armoury at Madrid. His banner, which it is claimed was embroidered by Queen Isabella, was cut in two; one half is preserved in Bogota, Columbia, and the other is at Caracas in Venezuela. (*d*) The epoch of conquest in other parts of America: in this will be collections to show the condition of the early natives of Central and South America; relics of the first discoverers and travellers, and collection of antiquities from all the republics of South America.

The third group refers to the Colonial period of the same continent. It commences with

the epoch of the Spanish Viceroys, and is intended to illustrate especially the development of the southern continent from the time of the conquest to that of the revolutions. Naturally religious relics will play an important part in this group, including as many genuine objects connected with the Inquisition as can be obtained. The epoch of the revolution will refer to that stormy period of South American history when the colonists rose up against the parent countries and threw off their yoke prior to commencing their own internal wars. Probably this section will be very complete, though hardly so interesting as the ones that precede it.

Too much praise cannot be accorded to Mr. Curtis for the ability and enthusiasm he has brought into this work; the success following his efforts is already assured, and we may predict in advance that the contents of the model La Robida will be worth the journey from here to Chicago to study. But I have another motive besides that of attempting to render justice to Mr. Curtis, and which I feel I have not sufficiently done. This really marvellous effort has other objects than to do glorious homage to Columbus, or to provide a special attraction to the visitors at the Exhibition. It is the avowed and absolutely justifiable intention of the United States to draw as closely to itself as possible, the countries of South America; and this embodiment of their history, this worthy homage fully paid to the great past of Spain and of her old colonies, will be a substantial step towards the realisation of that dream of federation so dear to most Americans. The struggle between ourselves and the United States for trade supremacy in those important countries which we have been accustomed carelessly to regard as ours by vested right, is close at hand, and the Columbian Exposition is assuredly going to mark an epoch in our commercial relations with South America. The sympathy between that continent and the United States is very sincere, and is based on an actual or a supposed community of interests; that it is real, the following facts and figures willl show.

United States Army and Navy officers have been sent by the supreme Government to every one of the republics and the colonies, as Commissioners, to awaken their interests, and to aid and direct the work of the various Governments and the local commissions; what excellent commercial missionary work these gentlemen will do, perhaps even without intending it, is obvious to you all. Every South American republic, and nearly every colony, has appointed Commissioners, and most of them have made large grants. In all, these grants amount now to over £400,000, and will be yet increased. In Brazil, the Federal Government has voted £100,000, and the different districts have also made large appropriations. It is true that the spectre of revolution is ever menacing this turbulent continent; but even revolution cannot destroy, it can only arrest, the flow of commerce, for which the United States is so actively digging a new channel. Columbia and Ecuador have each subscribed £20,000; Peru, Bolivia, Chile, Costa Rica even, the same amount; Argentina has found £200,000 (there is always money for war or exhibitions); Nicaragua, Guatamala, Honduras, Mexico, and Uruguay are all pressing forward with Commissioners and funds. The President of Paraguay has received *carte blanche* from his Congress to expend what he deems necessary; and the West India Islands are following suit.

Are stronger indications than these required to awaken our manufacturers to this concerted attack on one of our great trade strongholds? I repeat that this effort of the United States is absolutely fair and frankly announced. And I desire to emphasise the fact that in pressing us to participate in their Columbian Exposition, the Americans show their wish to give us every chance. This is no fanciful picture of the danger we incur, that I have attempted to sketch, and with this warning to our manufacturers and our traders, I pass on to another subject.

XXIII.—The Ethnological Museum.

If the plan which has been elaborated by Professor Putnam is carried out, a very complete ethnological exhibit will be made. It is intended to find room for this display in the hall of the Liberal Arts, but it is a question whether there will be sufficient space in this vast building. Like the historical portion of the transportation exhibit, that of the Columbus relics and some others, the ethnological collection will have little or no commercial interest, but only a scientific value. Foreign co-operation, therefore, will be entirely disinterested, and in order to awaken the interest of those connected with this subject, too much publicity cannot be given to Professor Putnam's plans, in the elaboration of which he is hoping to obtain aid from different parts of the world. He was appointed Chief of the Ethnological Department last September, and a grant of

£30,000 was made to defray the expenses of the exhibit. The most important part of the collection will refer to North and South America. Commencing with the traces of the existence of man in the northern hemisphere, and south of that part which then lay beneath a sheet of ice, the conditions of human existence will be represented by illustrations that will include the geology, the flora, and fauna of the period; the latter will contain actual specimens or reproductions of the mammoth and the mastodon, the reindeer, musk ox, and other animals which then existed far south in the continent. Portions of human skeletons and relics of human work have been discovered in the glacial gravel of this early period. After this will follow an exhibit of the races which still inhabit arctic regions; their summer and winter houses, boats, dogs and sledges, utensils, weapons, and costumes, as well as life-size figures of men, women, and children. Other collections will illustrate the northern tribes on the west side of the continent, Indian tribes living in the interior, and, as far as possible, by means of actual relics or by reconstruction, the habitations, arts, and customs of the various tribes living in the eastern portion of the country at the period of its earliest settlement by Europeans. This will be chiefly obtained by information gathered from 15th century writers, from old village sites, and from native burial places; so, also, the tribes of the southern portions of North America, of Central and South America, will be represented as fully as time and means permit.

Most of these objects will refer to periods of which tradition, history, and actual relics have handed down evidence. But there exist in America wide and deeply interesting evidences of pre-historic life on the American Continent; models of the most important earth works and mounds of the central portion of the country will be prepared, as well as carefully made plans and sketches. The great earth works in Ohio, in which are combined squares, octagons, circles, and other figures, often of large size, will be represented in this way as well as the different kinds of mounds. A model will be made of the great mound Cahokia, nearly a hundred feet high; another will be shown of the great serpent mound of Ohio, an earth structure 1,400 feet long, and the symbol of ancient worship in North America. The immense mounds, representing man and various animals, of which several exist in excellent preservation in Wisconsin and Minnesota, will be reproduced, and this part of the subject will be further illustrated by plans and drawings of all the important mounds known in North America. Associated with these objects will be a museum of the contents of the mounds; implements and ornaments of stone, copper, silver, bone, and other materials that were fashioned and utilised by this ancient people.

Another class of exhibits will be models of the ancient cliff houses and ruined pueblos of Colorado, Arizona, and New Mexico, with a large collection of ancient pottery, implements, and ornaments taken from them; models of the existing pueblos, such as those of Moki and Zuni, which appear to form a direct link with the past races, of which only ruins remain. Then will come the reproduction of some portion of those great stone buildings in Central America, Mexico, and Peru, of which there is but little knowledge. The ruins of Yucatan afford rich material for this part of the subject, and will be illustrated by reproductions, models, and pictures of this ancient architecture, and of the hieroglyphic records that abound within the temples; one of the most important of these structures, known as the Portal of Baoma, it is intended shall form the entrance to the great court in which all these objects will be arranged. To give an air of life to these relics of a dead and vanished time, many groups of natives, selected from different tribes of north, central, and south America, will be brought to Jackson-park, where—living in their own huts—they will be engaged during the period of the Exhibition in following their special industries, such as pottery making, weaving, basket making, &c.

Such a scheme as has been sketched out in the foregoing lines, from information furnished by Professor Putnam, suggests the necessity of much labour and of very earnest co-operation. In this Professor Putnam has been fortunate in obtaining the colaboration of Mr. W. E. Curtis, of the State Department, and chief of the Latin-American section. This gentleman, many months ago, despatched agents to all the countries of South America in connection with his own special work, and these are also engaged in gathering material for the ethnological display. The various museums from the different States of the Union are also assisting, as well as the various consuls in Mexico and Central America, while an expedition has been despatched to Greenland, Alaska, and Siberia for the same purpose. Special commissioners have also been sent to various parts of Asia and Africa to collect

ethnological material. The work is, therefore, proceeding with energy and method, and it is hoped that the appeal for help to the scientists of this country and on the Continent will not be in vain. It is intended after the Exhibition to establish a permanent ethnological musenm at Chicago.

XXIV.—Protection against Fire.

We have heard a good deal about the danger to which exhibits in Jackson-park will be exposed, from the alleged inflammable nature of the buildings. I should like to dispel this belief, which has no foundation in fact. It was originally contemplated to employ timber for the roofs of all the buildings excepting those of large span, and had this been done there is no doubt that during the hot and dry summer season there would have been considerable fire risks. But all this has long since been changed; it is true that the foundations, walls, and general frame work of nearly all the buildings is to be of wood; but the roofs, excepting those of quite insignificant dimensions, will be of steel, and there need be no more apprehension of fire than there was during previous exhibitions held in London or Paris. The exterior and interior of all timber walls will be covered with a fire-proof plaster, and all the complicated framing upon which the elaborate architectural effects are built up, will be embedded in the same material. Within the various buildings, timber, where it is exposed, will be protected with a fire-resisting paint; in short, every precaution that care and skill can suggest will be employed to secure the safety of the structures and their contents. In connection with this subject, some very interesting experiments will soon take place in Jackson-park. Some time since every paint manufacturer in the United States was requested to join in a test of so-called fire-proof paint. Only seven firms responded to this appeal, and a series of small wooden buildings are now being erected to put the pretensions of these makers to the proof. They will be covered with match-boarded roofs, over which canvas is strained, and they will be painted with various compositions inside and out. Efforts will then be made to set fire to these sheds by means of powerful electric currents flowing through defective conductors; such of the buildings as resist these tests will afterwards have combustible materials steeped in kerosine placed within them, and set on fire. The contractor whose paint is proved by these experiments to be the most resistant, will supply the executive with their compositions. Some of the competing firms have already carried out experiments on these lines, with reputed success. It need hardly be added that the amount of paint required to protect the exposed timber work within the buildings will be enormous.

Doubtless, these experiments will be of extreme interest, and very instructive. The Executive will, however, do well to remember that, with conflagrations, as with many other things, it is always the unexpected which happens, and that, despite all their care, a hundred unforeseen causes may exist to start a fire in one part or another of Jackson-park. Probably defective electric conductors will be a most fruitful source of danger, and, as such an enormous amount of energy will be constantly distributed through some hundreds of miles of wire, the risk from this cause will be largely increased. It is intended that the organisation for the prevention and extinguishing of fires shall be as perfect as even the advanced practice in the United States will admit. Mains are being laid down throughout the grounds, to which branches are connected, and a great number of fire hydrants are attached. The water supply will be practically inexhaustible, and the pumping power amply sufficient to meet even extraordinary contingencies. At the present time, this service is being placed in working order; for there is probably more danger from fire during the erection of the buildings than after the Exhibition is opened.

A powerful combination of insurance companies will issue policies covering risks upon the buildings, and, later on, upon the contents. And it is said—though I do not make this statement with official authority—that a floating insurance of 300,000,000 dollars will be effected by the Executive upon the Exhibition and its contents during the year 1893.

In addition to the fire service, the water supply for innumerable requirements during the time of the Exhibition will be—and it may here be mentioned that it is intended that the sanitary arrangements shall be—entirely satisfactory. The sewage will be collected by mains from all parts of the ground, and delivered into tanks near the lake, where it will be subjected to chemical purification; and only the effluent water will be discharged into the lake. Provision will be made for testing different systems of treating sewage that may be extracted.

XXV.—Classification of Exhibits.

A special committee was nominated at Washington to determine the general scheme, and to work out in minute detail, the system of classification which should be adopted for exhibits at the Columbian Exposition. The principle adopted was that of classification by objects, the intention being that objects of the same class should be arranged together, whether sent by American or foreign exhibitors. This method has been definitely abandoned, the Executive having realised the extreme inconvenience, not to say impracticability of foreign exhibitors having their goods scattered over numerous departments throughout the Exposition. Of course a certain amount of subdivision is absolutely necessary; for example, machinery must be shown in the Machinery Hall, pictures in the Fine Arts Gallery, agricultural exhibits in the section reserved for that purpose; and objects relating to the industrial arts, in the Industrial Arts Building. But apart from these broad lines of classification, the Chicago Exposition Executive impose no regulations upon foreign exhibitors, excepting that they shall follow the official classification of their goods in the spaces that have been reserved for them in the several buildings. It is understood, so far as this country is concerned, that we are at liberty to place—with the exceptions above referred to—all our exhibits within the great Industrial Hall, where the area of our court covers 120,000 square feet; it is also understood that if the British exhibits be sufficiently numerous to require a greater space, such exhibits shall be placed within the buildings to which they officially belong, and, to provide for this desirable contingency, ample space has been reserved by the Executive within these buildings.

Turning to the official classification, we find that the exhibits are divided into twelve departments; these departments being divided into groups, and the groups into classes, of which the following is a summary:—

Department A.—Agriculture, Forest Products and Forestry, Machinery and Appliances (Class 1 to 118).—In this department, Group 1, is for cereals, grasses, and forage; Group 2, bread, biscuits, pastes, starch, gluten, &c.; Group 3, sugars, syrups, confectionery, &c.; Group 4, potatoes, tubers, and other root crops; Group 5, vegetable products of the farm not otherwise classed; Group 6, preserved meats and food preparations; Group 7, the dairy and dairy products; Group 8, tea, coffee, spices, hops, and aromatic and oleaginous vegetable substances; Group 9, cotton, flax, wool, silk, and other fibrous and hairy substances; Group 10, pure, and mineral waters, natural and artificial; Group 11, whiskies, cyder, liqueurs, and alcohol; Group 12, malt liquors; Group 13, machinery, processes and appliances for fermenting distilling, bottling, and storing beverages; Group 14, farms and farm buildings; Group 15, agricultural literature; Group 16, farming tools, implements and machinery; Group 17, miscellaneous animal products—fertilizers and fertilizing compounds; Group 18, fats, oils, candles, &c.; Group 19, forest products—forestry.

Department B.—Viticulture, Horticulture, Floriculture (Classes 119 to 171).—Group 20, viticulture; Group 21, horticulture; Group 22, floriculture; Group 23, arboriculture; Group 24, pomology; Group 25, preserved fruits and vegetables; Group 26, appliances and methods of horticulture, floriculture, arboriculture, &c.

Department C.—Live Stock.—Domestic and Wild Animals (Classes 172 to 217).—Group 27, horses, asses, mules; Group 28, cattle; Group 29, sheep; Group 30, goats, llamas, camels, and other domestic animals; Group 31, swine; Group 32, dogs; Group 33, cats, ferrets, rabbits, &c.; Group 34, poultry and birds; Group 36, wild animals.

Department D.—Fish, Fisheries, Fish Products and Apparatus for Fishing. (Classes 218 to 268).—Group 37, fish and other forms of aquatic life; Group 38, sea fishing and angling; Group 49, products of the fisheries and their manipulation; Group 41, fish culture.

Department E.—Mines, Mining, and Metallurgy (Classes 269 to 397).—Group 42, minerals, ores, and native metals; Group 43, building stones and quarry products; Group 44, metallic fuels; Group 45, grinding and polishing substances; Group 46, graphite, clays, asbestos, &c.; Group 47, limestone, cements, and artificial stone; Group 48, miscellaneous useful minerals and compounds; Group 49, metallurgy of iron and steel, and their products; Group 50, aluminium and its alloys; Group 51, copper and its alloys; Group 52, placer, hydraulic, and drift mining; Group 53, quarrying and working stone; Group 54, tools and appliances for underground mining; Group 55, boring and drilling mining machinery; Group 56, pumping, draining and hoisting mine machinery; Group 57, moving, storing, and delivering ores, &c.;

Group 58, apparatus for crushing and pulverising; Group 59, sizing appliances; Group 60, extraction of gold and silver by milling; Group 61, extraction of gold and silver by lixiviation; Group 62, extraction of gold, silver, and lead by fire; Group 63, metallurgy of tin, tin-plate, &c.; Group 64, metallurgy of zinc, nickel, cobalt; Group 65, metallurgy of antimony, and other metals not specifically classed; Group 66, assaying apparatus; Group 67, history and literature of mining and metallurgy.

Department F.—Machinery (Classes 398 to 474).—Group 68, motors and apparatus for the generation and transmission of power, hydraulic and pneumatic apparatus; Group 69, fire-engines and apparatus; Group 70, machine tools and machines for working metals; Group 71, machinery for the manufacture of textile fabrics and clothing; Group 72, machines for working wood; Group 73, machines and apparatus for type setting, printing, stamping, embossing, and for making books and paper working; Group 74, lithography, zincography, and colour printing; Group 75, photo-mechanical and other mechanical processes of illustrating; Group 76, miscellaneous hand tools, &c., used in various arts; Group 77, machines for working stone, clay, and other minerals; Group 78, electric welding, forging, &c.

Department G.—Transportation: railways, vessels, vehicles (Classes 475 to 518).—Group 79, railway plant and equipment; Group 80, cable transportation; Group 81, electric railways; Group 82, transportation on common roads; Group 83, aerial, pneumatic, and other forms of transportation; Group 84, marine, lake and river transportation; Group 85, vessels of war and of defence.

Department H.—Manufactures (Classes 519 to 717).—Group 86, chemical products; Group 87, paints, colours, and varnishes; Group 88, type writers and stationery; Group 89, upholstery and interior decoration; Group 90, ceramics; Group 91, tiles, mosaics, and tesseræ; Group 92, art metal work; Group 93, glass and glassware; Group 94, stained glass; Group 95, art carving; Group 96, gold and silver ware; Group 97, jewellery; Group 98, horology; Group 99, silk and silk fabrics; Group 100, fabrics of vegetable and mineral fibres; Group 101, yarns of woven goods, cotton, linen, &c.; Group 102, woven and felted goods of wool and mixtures of wool; Group 103, clothing and costumes; Group 104, furs and fur clothing, &c.; Group 105, laces, embroideries, &c.; Group 106, accessories to the toilette; Group 107, travelling equipments; Group 108, rubber goods, &c.: Group 109, toys; Group 110, leather; Group 111, scales; Group 112, war material; Group 113, lighting apparatus; Group 114, heating and cooking apparatus; Group 115, refrigerators, hollow metal ware, &c.; Group 116, wire and perforated metal goods; Group 117, iron gates, railings, &c.; Group 118, safes, hard ware, cutlery, &c.

Department J.—Electricity (Classes 718 to 769).—Group 119, apparatus to illustrate the phenomena and laws of electricity and magnetism; Group 120, thermo-electric batteries; Group 121, secondary batteries; Group 122, dynamos, &c.; Group 123, transmission and regulation of the electric current; Group 124, electric motors; Group 125, electric lighting; Group 126, electric heating; Group 127, electro-metallurgy; Group 128, electric forging, &c.; Group 129, the electric telegraph; Group 130, the telephone; Group 131, the phonograph; Group 132, surgical electricity; Group 133, miscellaneous applications of electricity; Group 134, history and statistics of electrical invention.

Department K.—Fine Arts: pictorial, plastic, and decorative (Classes 770 to 773). —Group 135, sculpture; Group 136, paintings in oil; Group 137, paintings in water colours; Group 138, paintings on ivory, porcelain, &c., frescoes; Group 139, engraving and etchings; Group 140, crayon and other drawings; Group 141, antique and artistic carving; Group 142, exhibits of private collections.

Department L.—Liberal Arts: education, literature, engineering, public works, music, and the drama (Classes 774 to 881).—Group 143, hygiene; Group 144, instruments and apparatus of medicine, surgery, &c.; Group 145, primary, secondary, and superior education; Group 146, books, journalism, &c.; Group 147, instruments of precision, &c., photography; Group 148, civil engineering and architecture; Group 149, government and law; Group 150, commerce, trade, and banking; Group 151, institutions and organisations for the increase and diffusion of knowledge; Group 152, social, industrial, and co-operative associations; Group 153, religious organisations and systems; Group 154, music and musical instrumants, the theatre.

Department M.—Ethnology, archæology, progress of labour, and invention (Classes 889 to 917).—This department has been so fully referred to in another part of the present paper, and has so little to do with the com-

mercial aspect of the Exposition, that it may be dismissed with the remark that it comprises Groups 155 to 172.

XXVI.—Cost of the Exhibition.

Although forming no essential part in the purpose of this paper, a few words may be added here on the subject of the estimated cost of the Columbian Exposition, its buildings and grounds, its organisation and working expenses. I have stated the total estimated cost of the principal buildings, but it is almost certain that this amount will be largely exceeded, partly because it is in the nature of estimates to fall short of actual expenditure, and partly because additions and alterations, yet unforseen, will surely be made in the Exhibition project. Some allowance indeed has been included for extra cost, and the Ground and Buildings Committee assume that the total outlay in their department will be, in round figures, £1,500,000. But even if this increased figure should prove sufficient, which is doubtful, it will not represent one half of the total amount necessary to carry the enterprise to a conclusion. Below is the most recent estimate given by the Grounds and Buildings Committee of the total expenses of the Exhibition, though it is evident that this estimate does not include a number of grants, subsidies, and other items :—

	£
Grading, filling, &c.	90,000
Landscape gardening	64,700
Viaducts and bridges	25,000
Piers	14,000
Waterway improvements	45,000
Railways	100,000
Steam plant	130,000
Electricity	300,000
Statuary on buildings	20,000
Vases, lamps, and posts	10,000
Seating	1,600
Water supply, sewerage, &c.	120,000
Improvement in Lake front	40,000
World's Congress Auxiliary	40,000
Construction Department	104,000
rganisation and Administration.	662,000
Operating expenses	310,000
Total	£2,076,300

Adding this to the estimated amount for buildings, the total sum required according to this statement is no less than £3,576,000. It will be interesting at a future date to compare this statement with the actual expenditure incurred at the Exhibition. This enormous sum will be raised in several ways; by a small Government grant, at present intended only for Government buildings and organisation; by subscriptions from the City of Chicago; by the entrance money, and by the amounts obtained from the sale of concessions and other privileges granted to contractors and exhibitors.

The available resources, according to the report of the Grounds and Buildings Committee referred to above, are in round numbers as follows :—

	£
Stock subscriptions	1,121,000
City of Chicago Bonds	1,000,000
Estimated gate receipts	2,000,000
Concessions and privileges	300,000
Salvage	200,000
Interest on deposits	6,000
Total	£4,627,000

To the resources above mentioned, have to be added the Government grant, and future subscriptions to stock. Such subscriptions are constantly being made, and although it is impossible to estimate what the total will be, it is confidently expected that the amount will be very large. A call of 60 per cent. has been made on the subscriptions already received, and over £600,000 have been paid in on this account, from more than 30,000 subscribers. Up to a recent date a delinquency of between 7 and 8 per cent. among the subscribers has been recorded; on the other hand a considerable number has paid up calls in full. There appears to be no doubt that the one million sterling to be obtained from the City of Chicago bonds will be realised without difficulty. Of course, the receipts from entries and concessions can only be estimated, but he amounts set down in the report appear reasonable; as regards the former, the two millions anticipated, seem to be based on a total of twenty millions of visitors, unless the present intention of charging two shillings entrance be modified. It is clear, however, before these amounts could be realised, that the Exhibition must be completed and opened, and some arrangements will have to be made to obtain advances on security of the gate money. We all remember how successfully this was done at the Paris Exhibition of 1889, but the process then adopted is entirely out of harmony with American methods, and the present intention is to obtain from the Government the necessary advances.

XXVII.—CONCLUSION.

I hope I have made it clear that the pre-eminence of the Columbian Exposition may be fairly claimed by its organisers, not only because it will be far larger than any international exhibition that has preceded it—that is simply a law of natural development—but because of the real beauty and grandeur of its buildings, and, I think, because of the greater variety, novelty, and interest of its contents. The development of industry in the United States has advanced at such a prodigious rate of late years, that no one can form even a faint idea of its present condition, except by facts and figures, than which nothing is more misleading. Last year I ventured to suggest several reasons why this Exhibition should be truly International, and to-day I find no reason to modify the opinions I then expressed. On the contrary, many significant facts combine to prove the correctness of those views, and that they were not overstated, at all events, so far as this country is concerned. There is a very general feeling of resentment against the United States, because she surrounds her industries with a high barrier of tariffs. Nothing could be more unreasonable than this resentment; it is the business of every country to guard its welfare in the way which seems best to itself, whether by great armies, powerful navies, or internal policy. And, in spite of all the impediments placed in the way of our industrials, no less than one-sixth of our total exports find their way through the protected ports of North America. This vast volume of trade is carried on to the mutual benefit of sellers on this side, and of buyers on the other side, of the Atlantic. It seems to me that among these great interests involved, there would be enough to occupy all the space that has been assigned to us at the Exhibition. Again, we have many special industries, the products of which are of the luxurious and costly kind, to acquire which is the privilege of wealth; and there is no country in the world that can compare with the United States in the number and capacity of such purchasers. This should prove a sufficient inducement to many manufacturers who may become exhibitors at Chicago, with every reasonable certainty of selling all that they may send, and of establishing permanent and profitable connections in the future. Americans are rapidly becoming leading patrons of art. The fact that most art students from the United States go to Paris to study, is probably the reason why the French school controls the American market. It is time that this condition of things is changed; and there is little doubt that it will be changed, if English artists respond to the invitation to exhibit, and are fitly represented in the noble Gallery of Fine Arts that will form so conspicuous a figure at the Chicago Exhibition. English sentiments still remain deeply implanted in American nature, and will respond freely to the feelings expressed by the noble English school, which won so much admiration and surprise at the Paris Exhibition of 1889.

I have pointed out that it is the avowed intention, in American official quarters, to make a bold stroke at our South American trade, and to wrest from us as much of our commerce in the western southern hemisphere, and elsewhere, as may be possible. Being forewarned of this approaching struggle, which is without unfairness and without bitterness, our manufacturers should be forearmed, and, by carrying the war into our commercial enemies' camp, should turn the Exhibition to their advantage, and prove to all the world the incontestible superiority of the goods which we export, both as regards quality and price. Whatever benefits the United States may derive from the policy of high tariffs, it is certain that such complete protection must act prejudicially on many industries, both as regards the quality of goods produced and the cost of producing them. This is an inevitable consequence of the absence of the healthy stimulus of competition. When, therefore, foreign purchasers have an opportunity of comparing at Chicago the relative values of our own goods side by side with similar articles made in the United States, I think there need be little fear of the result. Of course, this has not a universal application; we cannot expect to hold the lead in every branch of manufacture, and it must be frankly admitted—and admitted, I hope, with due admiration of American ingenuity, skill, and enterprise—that in many things the United States has left us far behind. Any attempt at competition in those directions would, of course, be useless, and only lead to disappointment and loss of money.

Another important inducement to manufacturers to be present at Chicago must not be lost sight of. The number of Americans visiting Europe increases year by year; for the most part they are wealthy and leave large sums of money behind them, and, fortunately for our trade, England is rising in favour with these

visitors. Many shopkeepers and manufacturers enjoy great support from American customers, and it would be bad policy for them to neglect the means which will be afforded them in 1893 for increasing this support and making new connections. Exhibitors of such goods as the wealthy American tourist loves to buy, will be remembered long after the Exhibition has been closed, and will be sought for in England by visitors who will remember their displays at the Exhibition.

To the horticulturist, the coming Exhibition affords the certainty of a rich harvest, for as it has already been pointed out, our preeminence in flower culture is undisputed, and this branch of industry is less hampered by tariff obstacles than most others.

Much machinery of varied classes may be exhibited with profit, chiefly for the benefit of foreign customers, but in some cases also to meet the demands of the American market. A large exhibit of objects connected with transportation—such as railway rolling stock and ship models—may be confidently expected; these would be shown, not with the expectation of any actual trade benefit, but for the information of Americans who sooner or later will visit Europe. With a more direct purpose, the manufacturers of bicycles and tricycles may be expected to attend, for they represent a very important industry, in which this country takes an undoubted lead. Patentees of machinery and of processes may, if their exhibits possess real merit, fairly hope to do business in the United States, and our most advanced steam-engine practice will certainly be represented there on a large scale. Altogether, one way and another, we may fairly hope that the area allotted to us in the Machinery Hall will be filled with representative exhibits, and that the displays in the Electricity and Minings Building will not be unworthy of the country. As regards agricultural exhibits, American manufacturers have taken so decided a lead in the implement trade, that there appears but a slender chance for the British exhibitor in America; but the classification in this department is so wide and varied that it embraces many objects in which we can be represented with profit; especially this is the case with live stock for breeding purposes, for which there is always a demand in the United States, and an exemption from duty.

To urge manufacturers to incur the trouble and expense of exhibiting at the Chicago Exhibition, on the merely sentimental ground of aiding in the triumph of a great work, would be absurd, although there are idealists on both sides of the Atlantic who see in the general advancement of humanity, sufficient reason for demanding on the part of others large pecuniary sacrifices. But an Exhibition can only be successful as a commercial enterprise, and any manufacturer would be as foolish to participate without reasonable prospect of benefit, as he would be to abstain from mere prejudice against the tariff. Let our manufacturers consider therefore carefully before deciding; they can obtain sufficient data from which to form a fair appreciation of the chances of profit or loss, and if the odds are in favour of the former, they may go to Chicago, certain of a reception such as they have never experienced before at any International Exhibition; a reception based on true generosity and friendship, from a nation speaking their own language, bound to them by ties of kinship, and by community of sentiment; competitors only so far as competition is inseparable in the struggle for preeminence.

DISCUSSION.

The CHAIRMAN said he expressed the hope, when he presided on the occasion of Mr. Dredge's former paper, that it would be followed by others at periodical intervals, giving further information on the same subject, and every one must have been gratified at the admirable manner in which that hope had been fulfilled. Mr. Dredge and Sir Henry Trueman Wood recently visited Chicago officially on behalf of the Royal Commission, and either of those gentlemen would be only too glad to afford further information on any point of detail to anyone who was interested. He was very pleased to see Mr. Higinbotham, one of the Chicago Executive, present, and hoped he would have something to communicate to the meeting.

Mr. HIGINBOTHAM said he had only just arrived in London, but had been captured that afternoon, and taken to the meeting. He would first refer to what had been said by Mr. Dredge with regard to the high buildings in Chicago, and the contemplated legislation with regard to them. The fact was that the central portion, or heart of Chicago, occupied about half a mile square, and into that space everyone in business wanted to get; it was bounded by the lake on one side, by the river on two others, and on the fourth by an immense system of railways, so that it could not expand, and that had led to the erection of these high buildings. He had calculated that if the whole of that space were covered with such buildings, taking thirteen which already existed as a basis, the number of people employed in that small area would be 1,400,000. That was obviously im-

possible; the people could not come and go, not even if the streets were double-decked, as had been suggested. With regard to the McKinley Tariff, he might say that the mercantile house to which he belonged, which imported as largely as any house in America, had not diminished its imports by reason of the new tariff; on the contrary, they had increased—the people wanted English goods, and would have them at any price. He continued:—Since the visit of your esteemed citizens, Sir Henry Wood and Mr. James Dredge, to our country, the great Exposition has assumed more definite shape as well as vaster proportions. The very valuable information given us by your honourable Commissioners has been of incalculable value to our enterprise, and has placed us under obligations to them as well as to your Government and people. We all feel very deeply the debt we owe for this assistance. It will serve to bring us into closer and, if possible, more friendly relations. Your artists, as well as your dealers in art, will find in our great and rapidly developing country a rich field well worth their cultivation. Your manufacturers are already well informed as to the present situation with us, and are alive to the necessity of keeping abreast of the growth of that vast Empire which our older neighbour—New York, recognizes as the Empire west of the Alleghanies. It is to-day the richest and most rapidly growing section of our country, if not of the world, and is worthy the best attention of all countries desirous of extending their commercial relations. Within a radius of 500 miles of Chicago may be found over 20,000,000 of people, or just about one-third of the population of the United States. The rapidly increasing wealth of our country has, doubtless, been brought to your notice, and I ask your pardon for stating that within the last twenty years the wealth of the United States has grown from about 43 billion dollars to over 63 billion dollars, an increase, I think, that is without a parallel in the history of the world. And when I tell you that in her agricultural and mineral resources only a small per-centage of the possible has been reached, you will not wonder that I do not hesitate to call your attention to the present state and magnificent possibilities of my native land, and particularly that portion of which my own city is the very heart and centre. Being yet a young man, perhaps you will best appreciate what I have said, when I tell you that, within a few miles of Chicago, I was born on a farm the farther side of which was the border line of a rude civilization—all beyond was one vast unbroken wilderness, only inhabited by wild animals and American Indians. Slumbering in the great valley of the Mississippi were the possibilities of a mighty empire that to-day is being felt throughout the world. The product of this valley supplies food to the nations of the earth, and here myriad homes are being established by honest toilers, that come to us from the more densely populated countries of the old world. Your own country has given us very many of our strongest and cleverest men. Countless numbers of our most thrifty citizens look to this land as their first love. Your interest in them and theirs in you serves as a bond between the two greatest nations in existence. Chicago is, as you know, the commercial centre of this rich section. From it radiate more arteries of trade than from any other commercial centre. As was said of an ancient city, so it may be said of Chicago, that all roads lead to Chicago. Do you wonder that we there wish, for manifold reasons, to produce a magnificent Exposition? Chiefest of these is a desire to give our people an opportunity to see that which a great majority of them could never see if it is not brought near to them. We are willing to spend a large amount of money and years of our lives, that our people may reap the benefit that such an Exposition will give. In joining us in producing this great Fair you are helping your own loved ones who have made homes with us, and become prominent factors in our social fabric, while they are prosperous and happy in the homes that dot the land. We can, by the medium of the Exposition, enable them to build a better, stronger, and more enduring civilisation than that which they now enjoy. If, in helping our people to rise to a higher plane, we enable them to become more liberal patrons of art, and larger consumers of your manufactures, we not only help them, but your own working people, as well as the manufacturers who employ them. If, perchance, a slight benefit shall thereby accrue to our city we shall be content. I presume the Commission recently sent to your city from our country has given you sufficient in the line of statistics relative to our Exposition. I trust you will pardon me if I say that, just before leaving home, I was one of a sub-committee of our Finance Committee to ascertain the cost of the Exposition. I will not weary you with details, but content myself with giving you the totals:—

Cost of grounds and buildings to May, 1, 1893	$13,000,000
Cost of Administration to May, 1, 1893	3,000,000
Cost of Administration after May 1, 1893	3,000,000
Cost of construction after May 1, 1893	2,000,000
	$21,000,000

This does not include the appropriations of foreign Governments, neither are included the sums appropriated by our own general and State Governments, which will swell the grand total to about 36,000,000 dollars, or £7,000,000. Permit me, in closing, to thank you, and to extend an invitation to come to our feast in 1893, where we will give you a hearty welcome, and endeavour to care for you kindly.

Mr. C. M. Kennedy, C.B., said the Royal Commission fully recognised the great services rendered by

Sir Henry Wood and Mr. Dredge, in going to the States to obtain the information which, through the Commission, was given to the public. The great meeting of the nations in 1893 would be attended by visitors from all parts of the world, and it was of the greatest importance to British commerce that those visitors from the far East, and Central and South America, should carry away with them a correct impression; but this could not be done unless there were a good representative display of English goods. The Royal Commission were proceeding by means of committees of advice, through whose means they hoped to be brought in contact with all branches of industry, and it would then be for the various individuals and firms to consider how far it would be to their advantage to be represented at the Exhibition. In many branches of trade Great Britain had at present command of the market, and that command ought to be retained. This was not only to the advantage of English capitalists and manufacturers, but in an even greater degree to that of the workpeople whom they employed. The Royal Commission would afford all the information in their power to any parties interested. We were engaged in a friendly rivalry with the United States in many branches of trade, and we should therefore take full advantage of the opportunity now offered.

Mr. R. S. McCormick said—I must thank you for the honour which you have conferred upon me, as the representative of the Columbian Exposition, in electing me to membership of this Society, upon whose roll are to be found the names of the men who have done most to place England in the foremost place which she holds in Art-Industries and Commerce, not omitting the name of my own great countryman, Benjamin Franklin. I must also express the pleasure which the appointment of the Council of the Society of Arts, with the consent of H.R.H. the Prince of Wales, your President, as a Royal Commission, gave to the Executive in Chicago, and the Commission appointed by the President to represent the United States Government, in matters pertaining to the Exposition, this appointment being a guarantee that Great Britain will take the prominent place in the Exposition worthy of her history and her place among the nations of the earth. Those who are disposed to complain bitterly of the effect of the McKinley tariff have entirely overlooked the fact, that of all the customers of Great Britain the United States is *facile princeps*, notwithstanding the tariff which is called hostile, though only a fair offset to your cheaper labour, cheaper money, and heavily subsidised steamship lines. The following is a list of England's twelve best customers, with the amounts taken by them, for the three quarters ending September 30th, 1891:—

United States	£21,448,747
Germany	14,494,312
France	12,127,706
Turkish Dominions..	£8,819,006
Holland	7,125,185
Brazil	6,529,071
Belgium	5,553,261
Italy	4,994,227
China, exclusive of Hong Kong ..	4,932,318
Russia	4,243,753
Spain..	3,887,365
Argentine Republic, including the Atlantic Coast of Patagonia ..	3,431,938

To the value of manufactured articles taken by the United States from Great Britain during the twelve months just elapsed, must be added the railway stock and securities of every kind which a financial storm compelled English holders to find a quick market for, and the United States was the only country able and willing to put a shoulder under this load. With a choice of a quick market for these securities, or narrowing of the market for your manufactures, is there any doubt as to what the choice would have been? It is now only necessary for me to express my own appreciation of the able paper which Mr. Dredge has just read. In Chicago he is looked upon as one of our own people, and we deeply appreciate the services he has already rendered to the Exposition, and the never-tiring zeal with which he seems determined to make it impossible for appreciation to keep up with obligation.

Mr. Lee Bapty, having spent a short time in Chicago last summer, said he soon recognised the wisdom of the choice of that city as the site of the Columbian Exhibition, even in preference to New York. He was very pleased to hear from Mr. Higinbotham, whose store in Chicago he well remembered, that notwithstanding the McKinley tariff, the exports from this country to the United States had increased. There were certainly one or two branches of business in which he understood the tariff was prohibitive; but he believed they were very very few and unimportant compared to the general trade.

Mr. Collins Levey, C.M.G., did not think there ought to be any difficulty in filling the space allotted to England at the Exhibition, considering our enormous trade with the States, and the fact that as much space was recently occupied at the Melbourne Exhibition by the colony. There were one or two points, however, on which he was sure intending exhibitors would be glad to be reassured. One was with regard to the patent laws; that new inventions should not be pirated if they were not patented in America. Another was in regard to the Customs. At the Centennial Exhibition he found every facility afforded by the officials at Philadelphia, but in New York there were great difficulties, and on more than one occasion he had to appeal to Washington before he could put the New York Customs officials in operation; on the present occasion there would probably

till be some little friction between New York and Chicago, and special precautions ought therefore to be taken. Lastly, he feared there would be some difficulty with regard to the American law forbidding the importation of contract labourers, which he understood was very strictly enforced, and would affect *employés* engaged at the Exhibition.

Mr. McCormick said he could assure the meeting that exhibitors of new inventions would be fully protected, and with regard to the last point, the Attorney-General of the United States had expressed the opinion that the *employés* of exhibitors, or persons in charge of exhibits, would be entirely exempt from the contract labour law. There would be no trouble at the Custom-house, as the goods would go in bond through New York, being taken from the ship direct to a freight car, which would deliver them in the grounds of the Exhibition, which would be practically a bonded warehouse during its continuance If he mistook not, this information had already been published.

Mr. G. N. Hooper congratulated the United States on having obtained the co-operation of the British Government, which would add greatly to the facilities for exhibition, and induce many to send who would otherwise have held aloof. At the recent exhibition in Spain, for want of the protection of the British Government, the space allotted to this country was only half occupied, and the exhibitors were placed at a considerable disadvantage compared with their foreign competitors. As a member of the London Chamber of Commerce, he had the opportunity of meeting the Commissioners who came from Chicago, bringing information and cordial invitations, and was very pleased to think that the Chamber of Commerce promised them its sympathy and support. Having visited Chicago within the last few years, he could endorse what had been said as to the magnificence of the city and the comfort of the hotels, and he would especially call attention to the luxurious accomodation provided on the railways, which rendered the journey from New York to Chicago, though it took about twenty-four hours, anything but tedious. You could sleep six or seven hours, obtain refreshments as easily as in a good hotel, and read or write with the greatest convenience; so that you arrived at your destination quite ready for the business or pleasure which awaited you. If the weather was hot, the cars were well ventilated, and if cold, they were warmed.

Mr. Dredge, in reply, said he was very pleased that Mr. Higinbotham had arrived in time to make such a useful supplement to his paper; he was essentially a representative Chicago man, but there were thousands like him, and that accounted for the prosperity of the city. Mr. McCormick had spoken of him in too flattering terms, but he must admit that he had only echoed what he had often heard on the other side of the water. It was gratifying to find a man of Mr. Lee Bapty's experience in such matters endorsing his view that Chicago was the best place in which to hold the Exhibition; and he could corroborate what Mr. McCormick had said in reply to Mr. Collins Levey.

The Chairman then moved a vote of thanks to Mr. Dredge, which was carried unanimously.

Miscellaneous.

VIENNA MUSICAL AND DRAMATIC EXHIBITION, 1892.

An International Musical and Dramatic Exhibition will be held at Vienna from the 7th May to 9th October, 1892.

The Exhibition will be held in the Rotunda and the surrounding gardens situated in the Prater, and will be divided into two sections, the first comprising a division illustrating the historical, artistic and technical development of all appliances connected with music and the drama. The second section to consist of a special Trades Exhibition, which will comprise all the productions of modern industry relating to the cultivation of music and the drama.

The scheme of the Exhibition is arranged as follows:—

A. *Memorable Biographical Events.*—Relics and objects of interest connected with celebrated musicians, dramatic authors and artists (past and present) associated with the opera, drama and ballet, such as pictures (paintings, engravings, photographs, &c.), autographs and medals, &c.

B. *Music.*—1. Instruments. Historical development of musical instruments up to the present day:—(*a*) Keyed instruments; (*b*) String instruments; (*c*) Wind instruments of wood and metal; (*d*) Instruments played by striking; (*e*) Various other instruments, viz: harmonicons, wood and reed instruments, chime clocks, orchestrions and the like; (*f*) Aids to performing music, such as tuning forks, metronomes, &c. 2. Graphic representation of music:—(*a*) Manuscript music showing the ancient style of copying the notes; (*b*) ancient musical printing, with characteristic examples of every period; (*c*) modern musical printing, from the first editions of Bach and Händel up to the present time. 3. Musical literature and instruction.—(*a*) Literature of the past and present: history of musical works and compositions. (*b*) Instruction. (1) Theoretical and practical works; (2) statutes and annual reports of musical schools and conservatoires.

C. *Theatre.*—Theatrical conditions of the past and present time—(1) theatre-building; (2) adjuncts to theatrical representations, decorations, theatrical

properties, costumes, &c.; (3) pictorial representation of theatrical exhibitions, sculpture, &c.; (4) dramatic works of all descriptions, including the libretti of operas, and ballet subjects; (5) scenic science, theatrical literature and critiques.

D. All home and foreign objects of interest coming under the above heads.

Musical and theatrical performances, particularly from the historical, national, and ethnological point of view, will be given during the Exhibition.

Applications for space should be made to the Committee, 11, Eschenbachgasse, Vienna, not later than 31st December, 1891.

NOTES AND HINTS ON THE VEGETABLE PRODUCTS OF TROPICAL AFRICA.

By John R. Jackson.

[Continued from page 62.]

Gum Euphorbium.—The milky juice of several species of *Euphorbia* solidify on exposure to the air. Some interest has of late years been attached to these juices for the purpose of mixing with rubber and gutta-percha, as well as for the manufacture of an anti-corrosive paint for ships' bottoms. The gum has been brought into England from St. Paul de Loanda and from Natal. Attention should be given to the juices of any species of *Euphorbia.*

Food Products.—There is probably not much to be done in the way of new fruits from tropical Africa. Any native edible fruits, however, which seem to have any points to recommend them, should be carefully collected and sent home, together with branches of the plant furnishing them, and flowers, if possible. Attention should also be paid to tuberous or edible roots, and, indeed, all products of an edible character. The "manioc," "mandioc," or "cassava" (*Manihot utilissima*), is cultivated in west tropical Africa for its large fleshy roots, from which tapioca is made. This plant might be worth extended cultivation for the preparation and exportation of tapioca.

Drugs.—A very large field is open in the discovery of new drugs. Any plant said to have medicinal properties, or to be used for any special complaint or disease by the natives, should be carefully collected, in every case with the flowers, and, if possible, the fruit also. A sufficient quantity of the part of the plant used, such as bark, root, wood, fruit, or foliage, should be sent home for experiment and trial.

The natural orders that are well known to yield valuable medicines should be carefully examined. Thus, any plants of the Rubiaceæ which furnishes cinchona bark, might be tested for bitter tonic, but wholsome properties; the Malvaceæ, or mallow family, for mucilaginous or demulcent properties; the Euphorbiacæ, for cathartic properties, and so on.

The kola nut (*Cola acuminata*) is perhaps one of the best-known medicinal plants of west tropical Africa. The tree grows to a height of about 40 feet, and its cultivation has spread of late years to central Africa, as well as to the African shores of the Mediterranean. It has also been introduced for cultivation into India, Ceylon, West Indies, Mauritius, Zanzibar, and other countries. Quite recently a demand has sprung up in the English markets for kola nuts; and a few months since they were quoted at about 2s. 6d. per pound, but have since declined to 3d. or 4d. wholesale.

The ordeal bean of Old Calabar, (*Physostigma venenosum*) is a perennial climber, with a woody stem some 50 feet high, growing near the mouths of the Niger and old Calabar river. The seeds, known as Calabar beans, contain an active principle, used in European practice in ophthalmic cases, as well as in tetanus and neuralgic affections. The plants might be worth cultivation. The beans fetch about 4½d. per lb.

Doundaké (*Sarcocephalus esculentus*).—This is a West African tree, belonging to the same order as the cinchonas (Rubiaceæ). It has attracted some attention in Europe since 1885, on account of its tonic and febrifugal properties. The fruit is edible, and is known as the Sierra Leone peach. The golden yellow colour might be turned to account as a dye.

Strophanthus, or Kombe.—Under these names the seeds of *Strophanthus hispidus*, and probably of several other species at present but vaguely known, have become very important medicines in European practice, possessing valuable cardiac properties. Considering the doubt attached to the determination of the scientific names of the several forms or species now brought into commerce, much care should be taken in collecting the leaves, flowers, and fruits of every form, and carefully marking them, so that on their arrival in England they may be accurately matched and determined. For commercial purposes, the fruits or follicles should not be gathered before they are ripe, as the seeds, being immature, shrivel in drying, and consequently lose some of their active principle. The seeds should not be extracted from the follicle, as they keep fresher by being left in the fruit. As *Strophanthus hispidus* is the most valuable of the species at present known, this particular plant should be carefully looked after, so as to ensure the highest return.

Cardamoms, the dried fruit of *Elettaria Cardamomum*, a product chiefly of Southern India, are always in demand, and the plant would be worth introducing into West Africa.

Vanilla.—This well-known and valuable article is the carefully dried fruit of *Vanilla planifolia*, one of the very few orchids that possess any economic value.

Its cultivation has never assumed any important position in any British colony. The plant would no doubt thrive in Western Africa. As medicinal plants of minor importance are very numerous in Western Africa, it would be impossible to enumerate them here. Many valuable hints on this subject may be obtained from the List of Economic Plants

of Western Africa, at p. 269 of Moloney's "Sketch of the Forestry of West Africa," published by Samson, Low and Marston.

Since the paragraph on "Lagos Rubber," published on p. 62 of last week's *Journal*, was written, further material has come to hand, which shows that, at present at least, there is little or no prospect of this particular kind of rubber becoming a commercial article.

[To be continued.]

Correspondence.

SECONDARY BATTERIES.

Mr. W. H. PATCHELL has sent the following correction of the first portion of his remarks:—"He believed the Correns grid was one of those seized by the German Government, and turned out of the Frankfort Exhibition, as it was thought to be an infringement of the Electrical Power Storage Company's Patent, held in Germany by the Tudor Company: it was really Mr. Sellon's grid, and was now used for the negative in the Electrical Power Storage Company's high-discharge type cells. The ribs in the Tudor plates, both positive and negative, were horizontal. In the Electrical Power Storage Company's high-discharge cell, the positive was practically the same as the Tudor, but the negative was the same as the No. 4 grid, which gave a perfect negative, as far as he knew at present. As mentioned by Mr. King last winter, the paste in the negative plates, when some eighteen months or two years old, began to show signs of shrinking, and, with the ordinary form of square pellet, would loose contact with the grid, but, with the lattice grid, the more it shrank the tighter it became."

General Notes.

INTERNATIONAL CONGRESS OF ELECTRICITY.—The subject of an International Congress of Electricity, to be held at Chicago, in connection with the World's Fair, continues to attract much attention in America. A report about the matter has been presented to the Director-General of the Exhibition by Mr. J. Allen Hornsby, Secretary of the Department of Electricity. During a recent visit to Europe, Mr. Hornsby discussed the question with several leading men of science in England and on the Continent; and he was encouraged by them to believe that, if certain conditions were complied with, the success of the Congress would be certain. They all agreed that the Congress should be held under the auspices of the United States Government. Invitations, they thought, should be issued by the Government to individual scientific men through the Governments of the countries to which the individuals belong. "This course of action," says Mr. Hornsby, "in the opinion of the authorities whom I consulted, will ensure an official character to the proceedings of the Scientific Congress, and will virtually pledge the various Governments to a recognition and adoption of the standards created."—*Nature.*

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

DECEMBER 16.—GENERAL PITT RIVERS, "Typological Museums, as exemplified by the Pitt Rivers Museum at Oxford." PROFESSOR FLOWER, C.B., Director of the Natural History Museum, will preside.

Papers for meetings after Christmas:—

"Spontaneous Ignition of Coal, and its Prevention." By PROF. VIVIAN B. LEWES.

"Burning Oils for Lighthouses and Lightships." By E. PRICE EDWARDS.

"Dust, and How to Shut it Out." By T. PRIDGIN TEALE.

"Iceland." By T. ANDERSON.

"Ancient and Modern Art Pottery of Japan." By ERNEST HART.

"Artistic Treatment of Jewellery: The Jewel and Address Caskets." By I. WILLIAM TONKS.

"Agricultural Banks for India." By SIR WILLIAM WEDDERBURN, Bart.

"The Scientific Value of Lovibond's Tintometer." By F. W. EDRIDGE-GREEN, M.D.

"The Agricultural Needs of India." By DR. J. AUGUSTUS VOELCKER.

"Travels in Indo-China." By LORD LAMINGTON.

"The Woodcuts of Gothic Books." By WILLIAM MORRIS, M.A.

"The Fisheries Department: its Position and Prospects." By J. W. WILLIS BUND.

"The Congo State." By CAPTAIN W. LOVETT CAMERON, R.N., C.B.

FOREIGN AND COLONIAL SECTION.

The meetings of this Section will take place on the following Tuesdays at Half-past Four o'clock and Eight o'clock respectively, notice of which hour will be duly announced:—

January 12, February 16, March 15, April 5, 26, May 24.

INDIAN SECTION.

The meetings of this Section will take place on the following Thursday afternoons, at Half-past Four o'clock:—

January 21, February 11, March 3, 24, April 28, May 19.

APPLIED ART SECTION.

The meetings of this Section will take place

on the following Tuesday evenings, at Eight o'clock:—

January 26, February 23, March 8, 29, April 12, May 17.

Cantor Lectures.

The following courses of Cantor lectures will be delivered on Monday evenings, at Eight o'clock:—

A. P. Laurie, M.A., "The Pigments and Vehicles of the Old Masters." Three Lectures.

Lecture III.—December 14.—The mediums used by the Old Masters, in tempera and oil painting. The preparation of the oils and varnishes, and the properties of the same.

Howard Lectures.

A Special Course of Six Lectures, under the Howard Bequest, will be delivered on the following Friday evenings, at Eight o'clock, by Prof. W. Cawthorne Unwin, F.R.S., "The Development and Transmission of Power from Central Stations."

February 5, 12, 19, 26, March 4, 11.

Juvenile Lectures.

Two lectures, suitable for a juvenile audience, will be delivered by Professor John M. Thomson, Sec. C.S., on the "Three States of Matter: Solid, Liquid, and Gaseous," on Wednesday evenings, January 6 and 13, 1892, at 7 p.m.

MEETINGS FOR THE ENSUING WEEK.

Monday, Dec. 14....SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. A. P. Laurie, "The Pigments and Vehicles of the Old Masters." (Lecture III.)

British Architects, 9, Conduit-street, W., 8 p.m. Mr. H. Townsend, "American Theatres."

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. D. Morris, "Tropical Plants and Flowers."

Tuesday, Dec. 15...East India Association, Westminster Town-hall, S.W., 2½ p.m. Dr. G. W. Leitner, "The Races, Religions, and Politics of the Pamir Regions."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. Henry Gill's paper, "The Sale of Water by Meter in Berlin."

Statistical, School of Mines, Jermyn-street, S.W., 7¾ p.m. Mr. Charles Booth, "Enumeration and Classification of Paupers and State Pensions for the Aged."

Pathological, 20, Hanover-square, W., 8½ p.m.

Royal Scottish Society of Arts, George-street, Edinburgh, 8 p.m. Mr. John Laing, "Destructive and Conservative Distillations of Mineral Oils and their molecular condition."

Wednesday, Dec. 16...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. General Pitt Rivers, "Typological Museums, as exemplified by the Pitt Rivers Museum at Oxford."

Meteorological, 25, Great George-street, S.W., 7 p.m. 1. Mr. William Marriott, "Report on the Thunderstorms of 1888 and 1889." 2. Mr. Frederick J. Brodie, "The Prevalence of Fog in London during the twenty years, 1871-1890."

Microscopical, 20, Hanover-square, W., 8 p.m. The Hon. J. G. P. Vereker, "The Resolution of *Podura*."

Patent Agents, 19, Southampton-buildings, W.C., 7½ p.m. 1. Discussion of the President's Address. 2. Mr. A. V. Newton, "Patent Agency: its Origin and Uses." 3. Messrs. Abel and Loubier, "Notes on the New German Patent-law."

North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7½ p.m. 1. Mr. E. F. Wailes will reply to the discussion on his paper on "Proposed Improvements in the Construction of the Bottoms of Ships and Steamers." 2. Mr. J. F. Walliker will reply to the discussion on his paper on "Pumping Arrangements, &c., for Steam Vessels." 3. Discussion on Mr. J. Jennings Campbell's paper on "Engines for Ships of War." 4. Paper on "Tonnage Measurement," by Mr. M. C. James.

Inventors' Institute, 27, Chancery-lane, W.C., 4½ p.m. Annual Meeting.

Thursday, Dec. 17...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Prof. L. C. Miall and Mr. A. R. Hammond, "Development of the head of the Imago of Chironomus." 2. Mr. G. M. Thomson, "Two species of Cumacea in New Zealand."

Chemical, Burlington-house, W., 8 p.m. 1. Miss K. Williams, "The Composition of Cooked Vegetables." 2. Messrs. S. E. Linder and H. Picton, "Some Metallic Hydrosulphides." 3. Mr. Harold Picton, "The Physical Constitution of some Solutions of Insoluble Sulphides." 4. Messrs. H. Picton and S. E. Linder, "Solution and Pseudo-solution." 5. Dr. A. Colefax, "The Changes Proceeding in Acidified Solutions of Sodium Thiosulphate when the Products are Retained within the System," and "The Action of Sulphurous Acid on Flowers of Sulphur." 6. Dr. Matthews, "The A and B Modifications of Chlorobenzene Hexachloride." 7. Drs. Armstrong and Kipping, "Camphrone, a Product of the Action of Dehydrating Agents on Camphor." 8. Dr. Armstrong and Mr. Rossiter, "Studies on the Dibromo Naphthalenes."

London Institution, Finsbury-circus, E.C., 6 p.m. The Dean of Winchester, "Winchester Cathedral."

Historical, 20, Hanover-square, W., 8½ p m.

Numismatic, 22, Albemarle-street, W., 7 p.m.

Junior Engineering Society, Westminster-palace-hotel, S.W., 8 p.m. Mr. S. H. Wells, "Engineering Practice in the Cleveland and North-East Coast Districts."

Friday, Dec. 18...Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Physical, Science Schools, South Kensington, S.W. 5 p.m. Mr. H. Kilgowie, "Interference with Alternating Currents."

Correction.—P. 58, col. 2, line 15 from bottom, *for* Elwood *read* Elwell; p. 60, col. 2, lines 13-22 *should be* 2-11.

Journal of the Society of Arts.

No. 2,039. Vol. XL.

FRIDAY, DECEMBER 18, 1891.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be given on Wednesday evenings, January 6 and 13, by Professor JOHN M. THOMSON, Sec. C.S,, on "Three States of Matter: Solid, Liquid, and Gaseous."

The lectures will commence at seven o'clock. A sufficient number of tickets to fill the room will be issued to members in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each member is entitled to a ticket admitting two children and an adult. Tickets are now in course of distribution, and members requiring them should apply at once.

CANTOR LECTURES.

On Monday evening, 14th inst., Mr. A. P. LAURIE delivered the third and concluding lecture of his course on "The Pigments and Vehicles of the Old Masters," in which he treated of the preparation of oils and varnishes, and of the properties of the latter as preservatives of fugitive pigments.

On the motion of the CHAIRMAN (Prof. W. C. Roberts-Austen, C.B., F.R.S.), a vote of thanks to Mr. Laurie for his valuable and interesting course of lectures was passed.

The first lecture will be printed in the number of the *Journal* for next week.

FOTHERGILL PRIZE.

Under the will of Dr. Fothergill (1821), funds were bequeathed for the offer of Medals for subjects, in the first instance, relating to the Prevention of Fire.

A Society's Gold Medal, or £20, is now offered for the best invention having for its object the Prevention or Extinction of Fires in Theatres or other places of public amusement.

In cases where the invention is in actual use, reference should be made to places where it could be inspected.

A full description of the invention, accompanied by such drawings or models as are necessary for its elucidation, must be sent in on or before the 31st December, 1891, to the Secretary of the Society of Arts, John-street, Adelphi, London.

The Council reserve the right of withholding the prize, in case there is nothing in their opinion deserving the award, or sufficiently complying with the conditions, sent in for competition.

Chicago Exhibition, 1893.

A meeting of the Royal Commission was held on Monday, December 14. Present: The Attorney-General, M.P., in the chair; Sir Frederick Abel, K.C.B , D.C.L., F.R.S., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Major-General Sir Owen Tudor Burne, K.C.S.I., C.I.E., Michael Carteighe, R. Brudenell Carter, F.R.C.S., B. Francis Cobb, Sir Henry Doulton, James Dredge, Francis Elgar, LL.D., Thomas Hawksley, F.R.S., John Biddulph Martin, W. H. Preece, F.R.S., Sir Robert Rawlinson, K.C.B., Prof. W. C. Roberts-Austen, C.B., F.R.S., with Sir Henry Trueman Wood, Secretary.

COMMITTEE ON AGRICULTURE.

The first meeting of this Committee was held on Thursday, 10th inst., in the Council Chamber of the Royal Agricultural Society, at 12, Hanover-square. Present: The Earl of Feversham in the chair; Sir Edward Birkbeck, Bart., M.P., Sir George Macpherson Grant, Bart., Sir Robert Jardine, Bart., M.P., Col. Sir Nigel Kingscote, K.C.B., Sir Jacob Wilson, Lieut.-General J. Michael, C.S.I., Mr. G. Mander Allender, Mr. Richard Bannister, Dr. James Bell, C.B., F.R S., Mr. J. Bowen-Jones, Mr. Ernest Clarke, Major Craigie, Mr. Walter Gilbey, Mr. Charles Howard, Mr. Ralph Palmer, Mr. Clare Sewell Read, Mr. John Thornton, and Mr. Christopher W. Wilson ; with Sir Henry Trueman Wood, Secretary of the Royal Commission.

Mr. Ernest Clarke (Secretary of the Royal Agricultural Society) accepted the office of Hon. Secretary to the Committee.

The Committee considered the Prize Sheet for Live Stock issued by the Chicago Executive, and appointed a Sub-Committee to examine it in detail, with a view to obtaining from the Executive precise information as to any points in the Prize sheet or Regulations which appeared to require explanation or modification.

PROTECTION OF INVENTIONS.

Her Majesty, by Order in Council, has been pleased to declare that the conditions of the Patent Act, 1883, under which an application for a patent is not to be invalidated by the exhibition of an invention at an International Exhibition, are to apply to the Chicago Exhibition; and also that exhibitors are to be relieved from the conditions of the above Act, under which they were required to give notice to the Comptroller of Patents of their intention to exhibit the article afterwards sought to be patented. The regulations also apply to designs intended to be registered.

COLLECTION OF ECONOMIC MINERALS.

The Royal Commission for the Chicago Exhibition are anxious to comply with a request made to them by the Executive Authorities of the Exhibition, that a typical collection of Economic British Minerals may be included in the British Section; and they are now applying to owners and managers of mines, asking for specimens of the principal British minerals. Mr. B. H. Brough, the Instructor in Mine-Surveying at the Royal College of Science, South Kensington, has kindly undertaken to classify and arrange the collection, and any suitable specimens may be addressed to him. What is required is not specimens of special value or rarity, but samples of ordinary ores, &c., so that the collection, when complete, may be fully illustrative of the mineral resources of the kingdom. At the close of the Exhibition the collection will be presented to an American museum.

COLONIAL COMMISSIONERS.

CEYLON.—The Royal Commission have received information that the Government of Ceylon have, with the approval of the Secretary of State for the Colonies, determined to appoint a Special Commissioner to arrange for the representation of Ceylon at the Exposition.

CAPE COLONY.—The Agent-General for the Cape Colony has informed the Royal Commission that the Cape Government have appointed a Special Commissioner to represent the colony at the Exposition, and that Mr. Ludwig Wiener, M.L.A., has been selected for the office.

Proceedings of the Society.

FIFTH ORDINARY MEETING.

Wednesday, December 16, 1891; PHILIP LUTLEY SCLATER, M.A., Ph.D., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Barrett, Arthur, 114, High-street, Kensington, W.
Foord, Alfred Stanley, Tay-villa, Richmond-gardens, Romford-road, Forest-gate, E.
Hindmarsh, George Lisle, 29, Regent quay, Aberdeen.
Hughes, Thomas W. R., 11, George-lane, Lewisham, S.E.
James, J. H. Cordner, 10, Mansion-house-chambers, 11, Queen Victoria-street, E.C.
Jarman, Captain Stephen, R.N.R., Dartmouth villa, Evering-road, Clapton, N.E., and 19, Birchin-lane, E.C.
Maund, John Oakley, 80, Portland-place, W.
Watney, John, Mercers'-hall, E.C.
Wyon, Allan, 2, Langham-chambers, Portland-place, W.

The following candidates were balloted for and duly elected members of the Society:—

De Winton, Major George, Junior United Service Club, S.W., and South Norwood, S.E.
Parker, Thomas, Newbridge, Wolverhampton.
Sandbach, Captain Arthur Edmund, R.E., A.D.C., care of Messrs. King, King, and Co., Bombay.

The CHAIRMAN, in introducing General Pitt-Rivers, said:—In the absence of my friend Prof. Flower, I have had great pleasure in acceding to the request that I should occupy the chair this evening. General Pitt-Rivers, who is about to address you on this occasion, is well known to us in the region of science as one of our leading authorities on anthropology. The science of man is a comparatively new science, but a very progressive one. One of the eight sections into which the British Association is divided is specially devoted to its advancement, as is also the Anthropological Institute, one of the principal scientific societies of London. No one in England has done more for Anthropology than General Pitt-Rivers.

Having formed a splendid and almost unrivalled collection of objects for the illustration of his favourite science, he has presented it to the University of Oxford. There it is excellently housed in a particular department of the museum, and carefully kept in order by a special curator. No one who has inspected this beautiful collection can be otherwise than impressed with its extent and completeness. In the wilds of Dorset, again, General Pitt-Rivers has founded and stored another museum of somewhat similar character, but, as he will presently explain to you, specially modified for the altered circumstances of the case. This also has been a most successful institution, as you will presently hear. I will say no more, but call upon General Pitt-Rivers to commence his address on Typological Museums, which, I am sure, we shall all listen to with great interest.

The paper read was—

TYPOLOGICAL MUSEUMS, AS EXEMPLIFIED BY THE PITT-RIVERS MUSEUM AT OXFORD, AND HIS PROVINCIAL MUSEUM AT FARNHAM, DORSET.

By Lieut.-General Pitt-Rivers, D.C.L., F.R.S., F.S.A.

Museums may be established for different purposes, and the objects in them should be collected and arranged to further the particular purposes for which they are intended.

Technical museums may be established for instruction in art; to improve the taste of those engaged in manufactures. Of these, the South Kensington Museum, with the origin of which this Society had much to do, may be taken as the type. The National Gallery, in this sense, may be regarded as a museum of painting for the encouragement of artists. In a technical museum, the object is simply to collect specimens, calculated to serve, if not as actual models, at any rate as examples of styles to be imitated: the historical arrangement of them is of secondary importance. Although no doubt the same purpose might be served, and the interest of the museum increased, if they were historically arranged; still it would undoubtedly be proper in a museum instituted for this purpose, that the primary arrangement should be from the standpoint of art. It is not a museum for general educational purposes, as it can never have been contemplated that the whole or the majority of the visitors should qualify as manufacturers or artists; or, if it is efficacious for general education, it is only so in the sense of improving the public taste.

Next we have to consider the purposes to be served by such an establishment as the British Museum. The British Museum was, no doubt, in its origin, pretty much what local museums have hitherto been, a collection of miscellaneous antiquities; some small, others of enormous size. The collections of late years have been enlarged and classified in historical grand divisions or geographical areas, and the additions have been made, as time went on, with more regard to scientific arrangement, in proportion to the advance of knowledge. But it has not been collected from the first upon any system, or with a view to any special purpose; certainly not for educational purposes. It has been necessary to obtain specimens as opportunity offered, and to exhibit them in rooms that are ill-adapted for displaying them historically, designed in subordination to architectural considerations, and not with a view to the best means of arranging the specimens. As a large store of antiquities, it is probably the most useful institution in the world for *savants*, who know what to look for and wish to study them, in order to form their own classifications and deductions. As an educational museum, it is simply bewildering, and although lectures have lately been given upon the collections, such lectures are available only for comparatively few persons, and those not the working classes, who go there to obtain knowledge, by examining the antiquities and forming their own ideas upon what they see. It would be impracticable ever to convert the British Museum into an educational museum. More than half the objects would have to be eliminated, and the apartments altered to suit an educational arrangement. It would spoil the museum for the use of *savants*. I call such a museum a Museum of Reference, or it might, perhaps, more properly be termed, a Museum of Research.

I hold that the great desideratum of our day is an educational museum, in which the visitors may instruct themselves. For good or for evil, it is not here the place to discuss the question, we have thought proper to place power in the hands of the masses. The masses are ignorant, and knowledge is swamped by ignorance. The relative numbers of the educated and uneducated are enough to ensure this. The knowledge they lack is the knowledge of history. This lays them open to the designs of demagogues and agitators, who strive to make them break with the past, and seek the remedies for

existing evils, or the means of future progress, in drastic changes that have not the sanction of experience. It is by a knowledge of history only that such experience can be supplied. It is true that the history of laws, customs and institutions cannot be displayed in museums. You cannot place the successive links of development side by side in such a manner as to appeal to the eye; but the material arts are capable of such an arrangement, and the knowledge acquired in the one branch will be, to some extent, available in the other. The law that Nature makes no jumps, can be taught by the history of mechanical contrivances, in such way as at least to make men cautious how they listen to scatter-brained revolutionary suggestions. The knowledge of the facts of evolution, and of the processes of gradual development, is the one great knowledge that we have to inculcate, whether in natural history or in the arts and institutions of mankind; and this knowledge can be taught by museums, provided they are arranged in such a manner that those who run may read. The working classes have but little time for study; their leisure hours are, and alway must be, comparatively brief. Time and clearness are elements of the very first importance in the matter under consideration. The more intelligent portion of the working classes, though they have but little book learning, are extremely quick in appreciating all mechanical matters, more so even than highly educated men, because they are trained up to them; and this is another reason why the importance of the object-lessons that museums are capable of teaching should be well considered.

For an educational museum originals are not necessary. Casts, reproductions, and models are preferable; the proper specimens can be more easily selected; they are infinitely less costly. Such collections are not dependent on the chance of obtaining what is wanted from original explorers. Museums of casts do not compete with the research museums, in which the originals should be stored. Models occupy less room than originals, and can be more easily arranged to exhibit sequence within a limited space.

In an educational museum, specimens should be selected that are useful in displaying sequence. These should be arranged so as to show how one form has led to another. When there is actual evidence of the dates of the objects, of course the arrangement must be for the most part in the order of dates. But when, as in the case of most prehistoric objects and many of the arts of savage nations, the dates cannot be given, then recourse must be had to the sequence of type, and that is what I term "Typology." It is not an accepted term, and I am not aware that it has been applied before to the study of sequence of the types of the arts. But it appears to me that a name is wanted for this branch of investigation, which the term "Typology" supplies.

If it were taken to imply the study of fixed types as characteristic of particular phases of the arts, it would be erroneous. It includes the growth, varieties, and developments of the several types. It supplies the want of dates by showing how certain forms must have preceded or followed others in the order of their development, or in the sequence of their adoption. It may be said, as a rule, that simple forms have preceded complex ones. Within certain limits this must be true, but it is not always the case, for, in many instances, progress consists in eliminating superfluous complexity, and reducing the expenditure of time and labour. We have in this, as in all mundane affairs, to deal with degeneracy and decay, as well as progressive growth: the two have gone on side by side. It is the work of typology to unravel the true thread of events, and place the objects in their proper sequence for the use of students. Typology forms a tree of progress, and distinguishes the leading shoots from the minor branches. The problems of the naturalist and those of the typologist are analogous. The difficulties are the same in both. In some cases the number of missing links makes it impossible to determine the true succession of forms. In such cases recourse must be had to survivals, as in the case of the majority of savage weapons or forms of art, in which the successive links, being made of wood or perishable materials, have decayed. But a theoretical, and fairly accurate development, may nearly always be traced amongst the arts of savages by objects in present use. When a simple form is suited to its environment, or when its use fulfils common purposes that cannot be better served by its successors, or when economy of labour is a desideratum, the simple form survives; as, for example, in the case of the common door-bolt, which is the father of all kinds of complex door locks, and which is still used upon the same doors as the contrivances that have sprung from it; or in the case of the common hand-made pots that are still baked in an ordinary turf fire in the Hebrides, at the same time as the most skilled

productions of our modern potteries. So in natural history, invertebrate and vertebrate animals and mammalia are all found living side by side in the same localities, although we know that they represent successive stages in the development of species. Typological sequence, or typological continuity, may be said to be established when the true succession of forms have been brought out. This is the object of an educational museum. Not only must the objects be specially selected and arranged for the purpose, but the building must be adapted to the proper display of them. Architectural features, handsome halls and corridors are impediments; at any rate, they are points of secondary importance. In my address to the Anthropological Section of the British Association at Bath in 1888, I suggested a rotunda as the best form for a national educational museum of arts, a plan of which was exhibited. The concentric circles of a circular building adapt themselves, by their size and position, for the exhibition of the expanding varieties of an evolutionary arrangement. In the innermost circle I would place the implements and other relics of the Palæolithic period, leaving a spot in the actual centre for the relics of tertiary man, when he is discovered. The simple forms of the Palæolithic period would require no larger space than the smallest circle would be capable of affording. Next in order would come the Neolithic Age, the increased varities of which would fill a larger circle. In the Bronze Age a still larger circle would be required. In the early Iron Age, the increased number of forms would require an increased area; mediæval antiquities would follow, and so on, until the outer circle of all would contain specimens of such modern arts as could be placed in continuity with those of antiquity. Separate angles of the circle might be appropriated to geographical areas, and where civilisations in the same stage of development are allied to one another, they might occupy adjacent angles within the same concentric ring. Models would be largely used to explain the *gisement* of the relics exhibited. The sections and sub-sections would be divided under the head of Arts, such as Pottery, Glass, Enamels, Architecture, House Furniture, Modes of Navigation, Land Transport, Horse Furniture, Tools, Weapons, Weaving Apparatus and Textiles, Metallurgy, Painting, Writing, Music, Mensuration, Sculpture, Ornamentation, Personal Ornament, Agriculture, Hunting and Fishing Apparatus, Trapping, Machinery, Fortification, Modes of Burial, Modes of Punishment, Monuments, Coins, Religious Emblems, Toys, Heating and Lighting, Food, Clothing, Basket-making, Narcotics, Medicine, Domestication of Animals, and so forth. A manufactory of reproductions, casts, and models, would be attached to the institution, in the same manner as that established in connection with the Museum at Mayence, under the direction of Professor Lindenschmit. The museum would be divided into departments, under the control of separate keepers. By such an arrangement, the most uninstructed student would have no occasion to ask the history of any object he might be studying; he would simply have to observe its distance from the centre of the building, and to trace like forms continuously to their origin. Where breaks in the continuity of any art must necessarily occur, references might be posted to show the position of the concentric rings and cases, in which the threads of connection might be taken up again and followed. Such a museum would require constant rearrangement, as knowledge increased, and the cases might, perhaps, be put on wheels to facilitate their readjustment. An iron building with a glass roof would be the best for the purpose, and the less ornamentation it had about it, to divert the eye from the main object of the establishment, the better. Existing buildings, such as the Olympia, might, perhaps, be made use of as a commencement, as it would not be necessary the building should be round, provided the arrangement was concentric. But the Olympia would not be half large enough.

I have been much interested to learn since my address was delivered to the Anthropological Section at Bath, that Professor Flower, who has already done so much in his Natural History Department, since it was transferred to South Kensington, to arrange the collections on an evolutionary plan, has independently thought out the idea of a large rotunda, for exhibiting the development of species and varieties. A letter which I have received from him gives a rough sketch of the kind of museum that he would propose for the purpose; the present building being, in his opinion, quite unsuited for scientific arrangement. I have little doubt, therefore, that eventually this idea of concentric arrangement will be carried out, and that we shall have somewhere in the metropolis two large rotundas—one for natural history, and

the other for the arts of life. Professor Flower embodied his views on the arrangement of a natural history museum in his address to the British Association at Newcastle in 1889, in which he expounded very much the same principles for a Natural History Museum that I had advocated for an Arts Museum at the meeting of the previous year at Bath. That views so similar should have suggested themselves independently to workers in two separate departments, affords satisfactory evidence that they are in harmony with the requirements of the age.

In order to explain more clearly what my method of arrangement is, I have had prepared a number of large diagrams, to show the continuity of several of the series exhibited in the Pitt-Rivers collection at Oxford. Some of these diagrams are very old, and formed part of lectures delivered at the United Service Institution in 1858-69, the Royal Institution in 1875, and elsewhere. Others are of more recent date, and are taken from my provincial museum in Dorsetshire. Most of the diagrams were used in a lecture on my collection that was delivered lately at Oxford, at Salisbury, and other places.

Having now laid before the meeting my views upon the evolution of types, I desire to make a few remarks on the evolution of my own collection now presented to the University of Oxford.

My attention was first drawn to this subject nearly forty years ago, when, in the year 1852, I was engaged as a subaltern officer on the sub-committee of small arms at Woolwich in the experiments which led to the introduction of the rifle-musket into the army. A large number of inventions were submitted to the committee for trial; and I was then led to take notice of the very slight changes of system that were embodied in the different inventions, and also of the fact that many improvements which, not being of a nature to be adopted, fell out of use, and were heard of no more, nevertheless served as suggestions for further improvements which *were* adopted; and it occurred to me what an interesting thing it would be to have a museum in which all these successive stages of improvement might be placed in the order of their occurrence. I made a collection of arms at that time, which was the foundation of the present museum. Although this collection of arms was not a very good one, as my means of collecting were small, it led to a museum of savage weapons, and ultimately of various other arts, which were exhibited at Bethnal-green and South Kensington for nine years. Mr. Herbert Spencer, in his "Principles of Sociology," published in 1876, thus speaks of it as he saw it at that time:—"The collection of implements and weapons arranged by Col. Lane Fox,* to show their relationship to common originals of the simplest types, suggests that primitive men are not to be credited with such inventiveness as even their simple appliances appear to indicate. These have arisen by small modifications, and the selection of such modifications has led unobtrusively to various kinds of appliances without any distinct devising of them." The portion of the museum relating to arms was described in an illustrated catalogue *raisonné*, which was in fact a treatise on the development of arms; this went through two editions at South Kensington, commencing in 1877. The collection afterwards grew to such size that I was anxious to see it housed in some public building, where it would be developed in other hands on the same lines, and I ultimately presented it to the University of Oxford. In doing this I made only one proviso of any consequence, which is contained in the deed of gift, viz., "that the general mode of arrangement should be maintained, and that no changes should be made in the details hereafter, except such as should be necessitated by the advance of knowledge, and should not effect the general principles originated by me." This took place in 1884. During the seven years that have elapsed since, the museum has been re-arranged in the order in which it was exhibited at South Kensington, so that, in the main, the order of the several series is exactly the same. Some new links have been added to the old series, and some new series have been introduced. This has been done in the first place by Professor Moseley, whose death has been so great a loss to science, and afterwards by Dr. Tylor and Mr. H. Balfour, and has been carried out to my entire satisfaction in every respect, except perhaps the great length of time that it has taken to re-arrange, which, I am informed, was unavoidable, as a building had to be erected for it, for which the University very liberally voted £10,000.

But these are not times in which anything can afford to remain buried seven years, and I have had some difficulty in persuading people, now that the collection is resuscitated, that it

* In 1880 I changed my name to Pitt-Rivers, in accordance with the will of the second Lord Rivers.

is the same Lazarus that was alive before. In the meantime, however, I have formed another museum, which, although it is a provincial one, is in some respects better than the first, because such series as it contains are more fully represented. The subject of provincial museums has been lately much discussed in the newspapers. I have often observed that a little knowledge of the subject is necessary to create an interest. I have often noticed that visitors to our larger museums will wander listlessly through the rooms until they come upon something they understand a little about. Then they open their eyes and prick up their ears. It is interesting to them to compare the products of other countries and people, in those particular branches of industry that they are familiar with. A local museum should, therefore, contain a good historical series of the prevailing manufactures or industry of the locality. Acting on this principle, it appeared to me that in a rural district, sparsely inhabited, with scattered agricultural villages, and ten miles from every town and railway station, the chief feature of the collection should be agriculture and peasant handicraft.* I cannot convey my views on provincial museums better than by describing my own museum, because it has been collected from the first on a definite system, and has undoubtedly been a great success.

No. 1 Room, 20 feet by 13, contains pottery, costumes, personal ornament, now in use by peasants in Germany, France, Spain, and other nations. Some of these are of archaic design, and are probably survivals. The 2nd Room, 19 feet by 14, contains carvings by Brittany peasants, chiefly of the 17th century; French pottery in present use, and village implements of various kinds. The 3rd room, 18 feet by 13, is devoted to a series of tools, household utensils, cooking appliances, &c., of different periods. The 4th Room, 24 feet by 14, has an additional series of country tools, and here commences a general series, illustrating the history of pottery, which is continued in Rooms 5 and 6, and includes a sufficient number of specimens of each division to represent their kind, viz.:—Ancient British, Silesian bronze age, Etruscan, Egyptian, Swiss Lakes, Cyprian, Greek, Roman, Saxon, Norman, Mediæval, English toft ware, English salt-glaze, Staffordshire, and other Old English wares, Scotch pottery, German, French, Swiss, Spanish, Italian, Persian, Anatolian, Japanese, Chinese, Moorish, Peruvian, Mexican. Then follows similar specimens of glass and enamels from different countries. Another general series, not yet arranged, will be devoted to sculpture and modelling. In the 5th and 6th Rooms are models of excavations made by me in the locality, the relics from which are arranged in the adjoining cases. These are available for archæologists who may visit the district to see what it contains of local interest. Other models of ancient monuments, 95 in all, have been made under my supervision by my archæological staff, three to four in number, who are constantly engaged upon the work. These models certainly form the chief feature of the museum, and they are unique. The 6th Room, 62 feet by 19½, contains also a general series of implements of the palæolithic, neolithic and bronze periods, iron age, Roman, Egyptian, and mediæval periods. The 7th Room, 81 feet by 24, is only in process of building. The 8th Room, 85 feet by 18, is devoted to agricultural implements and appliances, and contains spades and agricultural tools of all kinds, showing the survival of the Roman wooden iron-edged spade in several parts of Europe; querns and grain-rubbers, some of which are in present use; a Norse mill, showing the earliest application of water power to the quern; grinding and winnowing machines; some models of crofters' cottages; a series of models showing the varieties of ploughs in present use in different countries; country carts, explained in the same manner by means of models; a series showing the development of locks and keys; a series of crates carried by country women of different countries on the shoulder, and collected expressly to show the women of my district how little they resemble the beasts of burden they might have been if they had been bred elsewhere. All these things are well ticketed, but an explanatory catalogue has yet to follow.

It would be a mistake, however, to suppose that the agricultural labourer can be reached by museums alone. Hodge, though better off than he has ever been before, is in a lower condition, morally and mentally, than at any previous period. He is too incessantly plied with pernicious doctrines to have a soul for anything above party politics. It is to the larger and smaller tradesmen in the towns and villages that such things as museums appeal, and, moreover, they must be supple-

* The population of Farnham and the neighbouring parishes is:—Farnham, 301; Handley, 868; Tollard Royal, 247.

mented by other inducements to make them attractive. Within a short distance of the museum, I have formed a recreation ground, called the Larmer Grounds, where my private band plays every Sunday in the summer months from three to five. This ground was attended during the last year by 16,839 persons from the neighbouring towns and villages. Not far off is an old house, formerly a hunting box of King John, which is open to the public, and were any amount of bread and butter, tea and buns can be obtained at slight cost. This during the last year drew 4,346 persons. The visitors to the museum in the same year amounted to 7,000 persons,* and the numbers at all three places have been increasing year after year. The people come from a radius of 20 miles round, and it has been very successful, in so far as the number of visitors is concerned. I have built a small Museum Hotel, at which visitors to the locality can put up, and which has first-class accommodation. Another, called "King John's" Hotel, has sprung up in an adjoining village. It has become the head-quarters of a local bicycle club, which is named after the place. Bicycling is an institution that must not be overlooked in any project for the improvement of the masses. The enormous distances bicyclists can go by road, especially on a Sunday, has rendered the population of country districts locomotive to an extent that has never been known before. Fifty to sixty bicycles are frequently seen at my Sunday meetings at the Larmer grounds, which average from 600 to 1,000 people; and the church on Sundays is crowded.

It is a mistake to suppose that the country towns are the best localities for such museums. Townspeople have other things to do than to visit the museum, which they can see every day, and which soon begins to pall upon them. The visitors from the country into the towns generally go there for business purposes, and have no time for museums. In the town of Dorchester, in which there is a museum equal in size to mine, and scarcely less attractive, I found that the attendance was only 2,826 during the year 1888, as against 7,000 at my museum in 1891. The outing is in itself an important accessory in a visit to a country museum. A pretty country, a pleasant drive in their country carts, an attractive pleasure ground, a good band, and lastly a museum, are the means which I have found successful, and which I am justified in recommending to those who wish to draw the people out of the towns into the country. But I do not wish to infer that I think any permanent good can be done in this way at the present time. Against agricultural depression, caused by foreign competition, it is impossible to contend. Burdens may be shifted from one shoulder to another by legislative enactments; but against the evil itself there is no redress on the political horizon, and, as long as that is the case, it is uphill work to fight against it, even though a landowner may spend his whole income in the endeavour to do so. The land, as a whole, will not produce one grain of wheat more, probably much less, by subdividing the ownership—substituting a large pauper population for a small and comparatively wealthy one, and driving capital away from it. The very reverse is the process that should be encouraged.

Public attention has of late been drawn a good deal to the advantages of museums in the Press. I am not myself so hopeful of the result as would induce me to devote the time and attention to the subject that I have done, had it not been to me, for many years, a hobby and an amusement. If no more good came of it than to create other interests, which would draw men's minds away from politics, that greatest of all curses in a country district, good would be done. If only a more scientific knowledge of the arts of life, and of the laws of nature affecting the development of those industries by which the working classes gain their living, the results would be beneficial. I have already hinted my belief that, by analogy, museums might be made the means of inculcating sounder views on social questions, and that they afford the only opening available to people who have so little leisure for study.

Whether or not my more ambitious scheme for a Typological Museum fails to be realised, at any rate my Provincial Museum may be claimed to be a success, judging by the constantly increasing numbers that are found to visit it, and that in a district which, at first sight, appeared very unpromising.

At the conclusion of the paper, General Pitt-Rivers exhibited and described a number of diagrams illustrative of his collection. The first was ones showing the evolution of the modern rifle and bullet through all its stages, some of which had entirely dropped out of public knowledge; and in connection

* This is the ordinary number of visitors, and does not include lectures or other meetings.

with this, he suggested the desirability of a similar series being arranged, before it was too late, of various electrical appliances, many links in which might easily be forgotten. Next came a large diagram showing the arms of savages, which in the beginning were constructed of mere natural sticks and portions of branches, thus giving the form to the weapon which was sometimes imitated afterwards, when the art became more advanced. Flint implements came next, and arrow heads, the leaf-shaped being the earliest. Bronze and iron weapons were not always copied from wooden ones, though a similarity in shape might sometimes be traced; this was illustrated by a series of sword-forms. When metallurgy was first introduced, only small pieces could be cast, and therefore short daggers were the earliest forms of this class of weapon; the copper implements were of the simplest form, and the later iron ones more complex. One particular shape of sword was found over a large portion of Asia, being very similar to a Greek sword figured on vases, and it was probably derived from the Greeks. Another series of diagrams was devoted to the development of ornament, and showed the changes which the loop, coil, and fret pattern had gone through; and another showed the cross, which, as a Christian symbol, was plainly derived from the Greek letters XP conjointly, which led naturally to the Celtic cross, still largely found in Scotland, whilst the Latin cross was a later form. The degradation of silver coins, from the stater of Philip of Macedon, was also shown. Another diagram illustrated how changes occurred through mistakes in copying, and were continued and increased until ultimately the original pattern was hardly recognisable. This was especially the case in representations of the human countenance, and had, in the opinion of Gen. Pitt-Rivers, led Dr. Schliemann into an erroneous belief that the figures found on certain vessels at Hissarlik were Trojan remains, as bearing the image of the owl-faced goddess, Glaukopsis Athene, whereas, in truth, there was nothing of the owl-face about them, but merely a degraded and conventionalized type of the human face.

DISCUSSION.

The CHAIRMAN said a great deal had been heard lately about the flow of people from the country into the towns all over England, but this paper showed how, by proper means, the population of the towns might be attracted to the country. He agreed with General Pitt-Rivers that the main object of the British Museum was to serve as a storehouse for the researches of savants, but in addition to that, there was room for some educational work to be done in some of the public galleries, and, under the direction of Professor Flower, something had been done in that direction in the Natural History Museum. He thought there would be some difficulty in introducing the word typology, because in natural history the word type had a particular meaning, and the type of a particular class of objects was one which exhibited the special peculiarities of the whole group; it would be rather confusing to use the word in a new sense.

Dr. E. B. TYLOR, F.R.S., said he could not add anything to the excellent account General Pitt-Rivers had given of his system of arranging museums, but he felt that the greatest of these museums, which would mark itself in no insignificant way on the present generation, ought not to be described without someone from the University of Oxford being present to bear testimony to the importance of the educational system it represented. Before this Oxford Museum was established, it was usual to look upon a museum as an assemblage of curiosities, which had to be pointed out and explained to the visitor with great care; otherwise even the most illustrative cases would make but very little impression on the ordinary untrained spectator. But the Pitt-Rivers Museum affected the mind of the intelligent stranger quite differently. There was no trouble to explain the system upon which it was worked. There might be some little trouble, even with the aid of good illustrations when, as on the present occasion, the actual specimens were not on view; but, when they were properly arranged, the slightest hint was sufficient to convey to the intelligent mind what they were there for; and then they told their own story. Very recently, there had been a good example of how it was educating the world at large. It often happened that a series might be made purely theoretical, by putting in their order a number of specimens which referred to one another more or less distinctly, thus showing where the curve of development had probably passed; but yet important links were often wanting, and the visitor went away possessed with the desire to find those links and present them to the Museum. Only a few weeks ago, they thus acquired a much desired link in in the history of stringed instruments. The late Mr. Carl Engel suggested that the strung bow must have been the origin of the whole series of stringed instruments, whether pianoforte, violin, or guitar. This view was proved to be correct when the instruments were arranged in a series, beginning with a strung bow. The difficulty, however, was to get the starting point—an authentic bow capable of being used both for hunting and twanging. One people, who were described as using the bow for this double purpose, were the Damaras; it was said that the hunter shot game with his bow during the day, and when he came home, sat by the fire and amused himself by twanging the string. Three or four weeks ago Miss Lloyd, who had spent some time in South Africa, sent them one of these bows, and it now stood at the head of the series of stringed instruments. He believed the idea of General Pitt-Rivers was destined to bear good fruit on the actual development of mankind. It had dissipated some notions as to the wonderful originality of early inventions, which, when seen in

connection with what had gone before, were found to be the natural product of a mind perhaps a little in advance of its fellows, but still in the main not so far removed from them. Although all country and county museums could not be expected to become museums of development, yet it was possible for them to treat local arts and other matters in that way. A country museum would very well show, in connected series, the arts and manufactures on which the people in the neighbourhood depended for their livelihood, and this could hardly fail to be useful in promoting further progress.

Sir George Bowen, G.C.M.G., said he had been much interested in seeing so well represented many of the arms of the aborigines of Australia, with which he became familiar during his twenty years' governorship of different colonies in that quarter of the globe.

Mr. F. W. Rudler said he had the privilege, many years ago, of becoming acquainted with the Pitt-Rivers collection, but he had never heard it called a Typological Museum before. Still, some distinctive title was required, the principle followed being so different from that usually adopted. Anyone who inspected it would be struck, not so much by its variety and magnitude, as by the obvious fact that all the specimens had been collected for a definite purpose, and arranged in a unique manner. In order to illustrate the evolution of the different types most effectively, a linear series was, no doubt, undesirable, and one could not but look with admiration on the project for an Anthropological Rotunda, but still, even such a scheme might, he thought, be open to improvement. Looking at the central circle representing the palæolithic period, it occurred to him that in walking round it, being a closed curve, one would never make any progress. You passed by a jump to the next circle, representing the neolithic, and though no doubt a great gap appeared between the two periods, that only arose from our ignorance. It seemed to him that a continuous spiral would, in some degree, be a better arrangement than a series of circles. If the Albert-hall could be cleared out, a good start might be made there. The question the General had raised was only part of a very large subject now under discussion by the Museum Association, a body which was moving somewhat on the lines of the Library Association, and which had already done good work. If General Pitt-Rivers would favour that association with his views on museums, he was sure he would receive the greatest possible sympathy, for all the curators who constituted the association were strongly imbued with the belief that a museum was one of the most important educational engines which could be developed.

The Chairman then proposed a hearty vote of thanks to General Pitt-Rivers, which was carried unanimously.

General Pitt-Rivers, in reply, said that, in tracing any particular series, there was always a danger of letting the imagination run riot to a certain extent; but where the same system became developed, as Dr. Tylor had shown it was now doing at Oxford, there was some guarantee that the principles established were correct. With regard to Mr. Rudler's remarks, he could only say that he had already suggested that the cases might be put on wheels, so that the arrangement might be altered from time to time as required. He was quite aware of the difficulty of introducing the word typology with regard to natural history, but he had never proposed to apply it to such specimens—only to continuity in the sequence of the arts of life.

Miscellaneous.

NOTES AND HINTS ON THE VEGETABLE PRODUCTS OF TROPICAL AFRICA.

By John R. Jackson.

[Continued from page 110.]

Oils and Fats.

There is always a brisk demand for vegetable oils in the markets of Europe, and, notwithstanding the spread of gas and of the use of the electric light, the demand is increasing, rather than diminishing. The largest number of new oil seeds that find their way to the English ports come from the west coast of Africa, and too often come without the slightest clue to their botanical identification. When new seeds are sent, a specimen of the plant, with flower and fruit, should accompany them. The necessity of the name of the plant being known is sufficiently obvious, for this knowledge often carries with it an indication of the nature or properties of the seed—whether the oil it contains is wholesome or poisonous or likely to prove useful for medicinal purposes or otherwise.

A large number of new oil seeds have come into the English market from the west coast of Africa during the last few years, but the supplies have mostly been intermittent. The following are amongst those to which some attention has been given, and for which, apparently, there would be a market if a constant supply was forthcoming.

Telfairia occidentalis.—This is a climbing plant belonging to the cucumber family (Cucurbitaceæ). The seeds, which contain a large quantity of sweet bland oil, are circular, about the size of a penny, and half an inch thick, covered with a net-like coating. They are contained in a large, ovoid, strongly ribbed, woody fruit, 12 to 18 inches long. The seeds themselves, when cooked, are taken as food by the natives. They are occasionally imported into Liverpool as oil seeds.

Under the name of "mutugo," the seeds of a kind of nutmeg (*Myristica angolensis*), a native of Angola, were first imported into Liverpool as oil seeds in 1884, and occasionally come into the same port at the present time in small quantities. They are said to contain about three-quarters of their weight of fatty oil. They are about three-quarters of an inch long and half an inch broad; they are ruminated or marked with irregular dark lines, like ordinary nutmegs, but have no smell, and very little taste.

Hyptis spicigera.—An herbaceous plant, belonging to the natural order Labiatæ, to which order belong the mint, sage, lavender, rosemary, &c. The seeds are very small and black, and contain a large proportion of oil. They were first imported in Liverpool from West Africa in 1883, and are still occasionally brought. In the West African Court of the Colonial and Indian Exhibition, in 1886, quantities of these seeds were exhibited.

Polygala rarifolia.—A shrubby plant, belonging to the Polygaleæ, or milkwort family. It is a native of Sierra Leone and Angola, and the seeds, which are small, and of a shining chocolate brown colour, are very rich in a clear oil. They are known as "maluku" seeds, and are sometimes brought into Liverpool, having made their first appearance in 1884.

Lophira alata.—A plant belonging to the order Dipterocarpeæ, a group of plants characterised by their resinous products rather than by their oils or fats; therefore, plants allied to *Lophira* might be expected to yield resins that should be useful in varnish making. The fruits of *Lophira alata* are somewhat oval, broad at the base, and pointed at the apex, two lobes of the calyx at the base are extended into wings (a distinct character of the Dipterocarpeæ). Each fruit contains a single seed, the oil of which is expressed in Senegambia, and used for cooking as well as for anointing the hair. The seeds frequently come in small quantities into the Liverpool market. They are generally known under the name of "Meni," but in Sierra Leone as "Laintlaintain."

Pentaclethra macrophylla.—A tree 50 to 60 feet high, belonging to the Pea family (Leguminosæ). The pods are from 18 inches to 2 feet long, 3 inches wide in the middle, tapering at both ends, and about 1 inch thick; they are of a brown colour, woody, and very strong. The seeds which they contain are irregularly oval, flattened, about 2 inches long by 1 inch broad in the middle, and about ¼ inch thick, of a shiny, chocolate brown colour. These seeds are eaten as food on the Niger, and the oil, which is expressed from them in large quantities, is used for cooking and also for greasing machinery, and is said to be a good oil for soap-making. The seeds sometimes find their way into Liverpool. The tree has been found in Senegambia, Fernando Po, Camaroons River, St. Thomas Island, Prince's Island, Gaboon, &c. It is the "Owala" of the Gaboon, and the "Opachala" of the Eboe country.

"M'poga" nuts, "Mabo" nuts, and "Niko" nuts. Under these three names, the hard bony fruits, without the fleshy coverings in which they are enveloped when fresh, come occasionally into the port of Liverpool from West Africa—mostly from Liberia and the Gaboon.

M'poga fruits are about 2 inches long, and from 1 to 1½ inches in diameter. They contain three or four roundish seeds, from which a very large percentage of oil can be expressed. The fruits of the mabo are oblique-ovoid in form, about 2 inches long and 1 inch in diameter; externally, they are very rough or channelled; the seeds of this nut are also rich in oil of a very fluid character. These fruits and seeds are both imported from Liberia. Niko nuts, which come also from Liberia, are of a similar bony nature, about 2 inches long and 1½ inches in diameter. The seeds, like the other kinds, contain a large proportion of oil. Neither of these have become established articles of trade, though the oil seems to be of a character that might become useful. Owing to the want of authentic specimens of leaves and flowers of the plants producing these fruits they have never been botanically identified. They may, perhaps, be a species of the genus *Parinarium*, belonging to the *Chrysobalaneæ*, a section of the Rose order (Rosaceæ), or more probably to the genus *Elæocarpus* of the natural order Tiliaceæ. It is very important to collect complete botanical specimens of all these plants and transmit them to this country for determination.

The seeds of any unknown plants should be examined for the presence of oil, and if found to contain oil, should be collected in sufficient quantity for experiment. Seeds thus collected for trial should always be accompanied by foliage, flowers, and fruits of the plant, by which means their botanical affinities and consequent name may be determined.

[To be continued.]

Notes on Books.

RULERS OF INDIA: CLYDE, AND STRATHNAIRN. By Maj.-Genl. Sir Owen Tudor Burne, K.C.S.I. Oxford: Clarendon Press, 1891.

The contents of the fourteenth volume of the "Rulers of India" series, which Sir William Hunter is editing for the Clarendon Press, are perhaps more fitly indicated by its second title, "The Suppression of the Great Revolt;" for the book is actually a clear though brief account of the Indian Mutiny, from its outbreak in May, 1857, to its final suppression in August, 1858, and the transfer of the powers of the East India Company to the Crown. It is only because they were the actual figures of the campaign that Sir Colin Campbell and Sir Hugh Rose were selected to give their names to this book.

To compress into the limits of 200 pages a narrative of a time so crowded with events, so full of interest, and so important in its results, was no very easy task, especially as the details of the history are still fresh in the memory of all who have reached middle age. It is only when, by lapse of time, details are forgotten, and when the generation which has made the history has passed away, that the really important events can be reviewed in their true magnitude, and history can be written. The time has perhaps come when it has become possible to estimate in their true proportion that series of rapidly changing events which began by nearly severing India from the British Crown, and ended by uniting the two empires in closer bonds than before.

To do this in a succinct and yet popular manner has evidently been the object of the writer, whose former connection with the two great soldiers above mentioned gave him special facilities for acquiring an intimate knowledge of the movements he describes; and the judicious manner in which the task has been accomplished will render his work useful, not only to the student of Indian history, but also to the larger public who may welcome an impartial record of the events connected with the last great crisis in the history of our country.

ELECTRICITY UP TO DATE. By John B. Verity. London: Warne and Co.

This is a popular manual, intended for the growing class of users of electricity. The necessary apparatus and plant employed for electric light installations is described, dynamos, arc and incandescent lamps, storage batteries, conductors, &c. The method of mounting and making a private installation is described, and the needful amount of information is provided for those who are in a position to obtain a supply of electricity from a public source. Chapters on the employment of electricity for motive power complete Mr. Verity's treatment of his subject.

TEXT BOOKS OF ORNAMENTAL DESIGN; NATURE IN ORNAMENT. By Lewis F. Day. With 123 plates and 192 illustrations in the text. London: B. T. Batsford.

In this profusely illustrated book Mr. Day deals fully with the multifarious aspects in which nature has been treated in ornament, and with those in which it can be treated with advantage. He divides his subject as follows:—Ornament in nature, nature in ornament, simplification of natural forms, elaboration of natural forms, consistency in the modification of nature, parallel renderings, tradition in design, treatment of animals in ornament, element of the grotesque, still life in ornament, and symbolic ornament. The author is not sanguine as to the conversion of the popular mind to the true principles of design; and he says that there is even still a superstition that ornament is designed by the aid of the kaleidoscope. He strongly urges the adoption of a special artistic treatment of nature, whether it is called conventionalism, or given any other name. On this he writes:—"Art passes through periods of affectation, when it becomes, before all things, urgent that opinion should be led back again to the forgotten grass-grown paths of nature. That is not our urgency now. If there was at one time within our memory some fear of artificiality in art, the danger now lies in the opposite direction of literalism; a literalism which assumes a copy of nature to be not only art, but the highest form of art; which ignores, if it does not in so many words deny, the necessity of anything like imagination or invention on the part of the artist, and accepts the imitative faculty for all in all."

He further affirms that the conventions of artists are not so far removed from nature as we are apt to think, and adds, that "trees do grow in Umbria as Perugino, and Raffaelle after him, painted them."

Mr. Day contends that, although it is necessary for the artist to know what has been done by others before him, he must make his convention for himself, and not accept one ready made. To accept the academic view, that some old, or more or less obsolete style, such as classic, Mediæval, or Renaissance is to be servilely followed, is to agree that "the tombs of buried peoples are heaven-sent habitations for live men."

He gives many illustrations to show how certain emphatic natural forms may be used in design, and, although they are exhibited in a rudimentary form, their identity can be seen; so that vitality of foliage may be seen to exist even in stone. He instances an example of a panel by the architect Street, in which the thistle is characteristically and energetically treated, although shorn of its leaves, its prickles, and the featheriness of its flower heads.

The examples which the author has collected are very varied, and exhibit the treatment of nature in design at different periods in various nations, as well as in many materials.

General Notes.

CHICAGO EXHIBITION.—It is stated that France has made application for 130,000 square feet of space in the Exposition buildings. The application for space for France was filed recently by M. Bruwaert, the French consul stationed at Chicago. He asked for the following allotment of space:—In the manufacturers' building, 100,000 square feet; in the fine arts building, 20,000; in the machinery hall, 10,000. The consul also desired space in the mines and mining, agricultural, and horticultural buildings. He announced at the same time that France would probably not construct a special State building.

Journal of the Society of Arts.

No. 2,040. Vol. XL.

FRIDAY, DECEMBER 25, 1891.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be given on Wednesday evenings, January 6 and 13, by Professor JOHN M. THOMSON, Sec. C.S., on "Three States of Matter: Solid, Liquid, and Gaseous."

The lectures will commence at seven o'clock. A sufficient number of tickets to fill the room will be issued to members in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each member is entitled to a ticket admitting two children and an adult. Tickets are now in course of distribution, and members requiring them should apply at once.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by members on application to the Secretary.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied post free for 1s. 6d. each, on application to the Secretary.

Chicago Exhibition, 1893.

The following Chambers of Commerce have consented to act as Local Committees in connection with the Royal Commission :—

London,	Leicester,
Barnsley,	Lincoln,
Barrow-in-Furness,	Pembroke,
Cardiff,	Sheffield,
Dundee,	Southampton,
Edinburgh,	Sunderland,
Exeter,	Wakefield,
Halifax,	Worcester.
Hull,	

The following Chambers, while unable to act as Local Committees, have expressed their readiness to distribute information in their respective districts :—

Birmingham,	Leith,
Glasgow,	Nottingham,
Greenock,	North Staffordshire.

Proceedings of the Society.

CANTOR LECTURES.

PIGMENTS AND VEHICLES OF THE OLD MASTERS.

By A. P. LAURIE, M.A.
King's College, Cambridge.

Lecture I.—Delivered November 30th, 1891.

The subject to which these lectures are devoted is one so wide reaching, and so complex, that it is only possible to deal with certain aspects of it, and take up a few points that seem of especial interest. Perhaps I cannot begin better than by stating clearly what I do not mean to do. In the first place, there is a great deal of information which is common property on this subject, and which I do not propose to consider here. We all know that the various coloured earths and ochres have been used in painting from the earliest times, and that they are permanent under the test of hundreds, indeed, thousands of years. We know that before the introduction of oil painting, white of egg was the favourite medium, and that oil painting in its main features has always been the same. I do not propose, then, to waste your time in considering in detail matters familiar to everybody already.

I have been studying for some years the literature of this subject, and, testing the statements contained therein, as far as I could by experiments in the laboratory, and I think I have succeeded in clearing up a few points and answering a few questions. I propose to give you here, as briefly as possible, what seems

to me to be the essential points in the technique of the old masters—the essential points, that is, regarding the picture, not as a work of art, but as a job executed in pigments, and meant to stand as long as possible without deterioration. On the whole, it seemed best to arrange the subject under three heads:—

(1) The preparation of the painting surface.

(2) The pigments; their preparation and properties.

(3) The mediums.

No doubt there will be some referring backwards and forwards, even in this arrangement, from one part of the subject to another; and I must further warn you that I shall not regard dates, but shall jump from a 15th century panel to the lid of an Egyptian coffin of 1500 B.C. without the slightest hesitation, if it suits my purpose. What we want, I take it, are good practical working methods, from any source that we can get them, while, at the same time, rejecting all vague uncertain utterances. The torment of the writings on these subjects is the amount of vague, speculative material introduced, with no distinction between what is known and what is guessed at.

We shall begin, then, by discussing the preparation of panels for painting, as very complete information can be obtained on this subject. Unfortunately, nothing so accurate seems to be known about the preparation of canvas. I shall not touch on that subject here, as much sifting of evidence is required first. To begin, then, with panels, our principal authority will be the MS. of Cennino Cennini, translated by Mrs. Merrifield. Cennino Cennini was a pupil of Agnolo, himself a pupil of Giotto, and wrote in 1437. This work is invaluable, especially as throwing light on the methods of fresco and tempera painting. It was first published in Italian by Tambroni, in 1821, and translated by Mrs. Merrifield in 1844.

Panels.

In preparing a panel for painting, it is essential that the wood should not warp or crack, and that the layer of plaster or gesso on the panel should not be liable to crack off. We accordingly find special precautions taken to guard against these dangers. Probably, the best guard against cracking and warping is to have *thoroughly* seasoned wood. This is not easy to secure, unless the wood has been stored by yourself. But there is another precaution for small panels, given by Cennino Cennini, which is interesting. He advises *boiling* them in water, to prevent warping or cracking. I have made some enquiries into this, and I find that it corresponds somewhat with a modern practice, namely, the steaming of wood to get it seasoned rapidly. I do not find, however, that this practice is regarded as the best by carpenters. They consider that slow air drying is the best. Apparently, the most important matter is to season the panel after it is cut to its final shape and size. The panel should be cut in summer and kept to next summer. If this is done, some will warp, twist, and crack, and may be rejected; others will survive the test, and are thus safe. The careful selection and seasoning of the wood is of the first importance. Cennini says little about it. He, probably, trusted to his carpenter to see to that for him.

Having now obtained a piece of wood of suitable size and shape, we must next prepare it with a fine surface of gesso, on which the picture is to be painted. Obviously the important point now is to prevent the possibility of the gesso peeling off. This can best be prevented by thoroughly roughening the surface of the wood, so as to give a tooth on which the fine plaster can hold, just as a plasterer marks his rough lime with the trowel, in order to enable the fine lime finishing the wall or ceiling to firmly adhere. This, then, being the most important matter, you will not be surprised to hear that the intelligent maker of panels for painting at the present day carefully smooths his wood before laying on the gesso.

Before quoting in full, as I propose to do, Cennino Cennini, on this matter of panel preparation, I shall briefly refer to the method used by the Egyptians in certain cases. The wooden coffin lids were prepared for painting on by being first coated with gesso, and it was my good fortune to be presented with a small crumb of such a coating by Professor Middleton, obtained from a coffin in the British Museum. There was a streak of blue pigment on this fragment, of which I shall speak in my lecture on pigments; but with that we have nothing to do at present.

On examining this portion of prepared surface, I found a thin coating of fine white plaster lying over a dark brown substance, resembling oil-cake in appearance.

I was somewhat troubled to make out what this substance could possibly be. It seemed about 1-16th inch thick, and must have lain between the white plaster and the surface of the wood. On moistening the fragment with

hot water it fell to pieces, the binding cement, or gum being dissolved, and then, on examining under a glass, the nature of this substance was revealed. It consisted of grains of sand mixed with wood fibres.

The way in which the panel had been prepared was now sufficiently obvious. The surface of the wood had been rubbed and torn up with sand mixed with gum water. Then the whole surface had been smoothed down, sand, wood fibres and all, and allowed to harden. Then on this curious concrete, bound to the wood by partially torn fibres, the fine white gesso had been laid. You see here some attempts to imitate this method of our own preparing, and I can safely recommend it. It has stood the test of 3,000 years. Passing, then, from this ingenious method, let us consider how Cennino Cennini mastered the same difficulties.

I cannot do better than quote directly from his work:—

"CHAP. 113.—*How to begin to Paint Pictures.*

"Now we are really going to paint pictures. In the first place, a panel of the wood of the poplar, lime, or willow tree must be prepared, on which to paint the picture. Let it be made quite smooth. If it be defaced with knots, or if it be greasy, you must cut it away as far as the grease extends, for there is no other remedy. The wood must be very dry; and if it be such a piece that you can boil in a cauldron of clean water, after the boiling it will never split. Let us now return to the knots, or any other defect in the smoothness of the panel.

"Take some glue (*colla di spicchi*), and about a glassful of clean water; melt and boil two pieces (*spicchi*) in a pipkin free from grease; then put in a porringer some sawdust, and knead it into the glue; fill up the defects or knots with a wooden spatula, and let them remain; then scrape them with the point of a knife till they are level with the rest of the panel. Examine if there be any nail, or other thing that renders the panel uneven, and knock it into the panel, then provide some pieces of tinplate, like *quattrini* (small pieces of money), and cover over the iron with them; and this is done that the rust of the iron may not rise through the ground. (1.) The surface of the panel cannot be too smooth. Boil some glue, made of parchment shavings, till the water be reduced to one-third of what it was at first, and, when put on the hands, if one hand stick to the other, it is sufficiently boiled. Strain it two or three times, put half this glue into a pipkin, add a third part water, and boil well together; then, with a hog's-hair pencil, large and soft, pass a coat of the glue over the panel, or foliage, or pyxes (*civori*), or columns, or whatever you work upon, that is to be covered with a ground (*ingessare*), and let it dry; then take some of your first strong glue (*colla forte*), and pass twice over you work, letting it dry well between each coat of glue, and it will be glued to perfection.

"Do you know the effect of the first glue? A weak water or liquor is absorbed from it by the wood, which operates exactly as if, when fasting, you eat a few comfits, and drank a glass of wine, which gives you an appetite for dinner; so this glue prepares the wood for the glue and grounds to be applied afterwards.

"CHAP. 114.—*How to fasten linen on panels.*

"Having thus spread the glue, get some linen cloth, old, fine, and white, and free from grease. Take your best glue, cut or tear this linen into large or small strips, soak these in the glue, and spread it with your hands over the surface of the panel; remove the seams, and spread it well with the palms of the hands, and leave it to dry for two days. And remember it is best to use glue when the weather is dry and windy. Glue is stronger in the winter. For gilding, the weather should be damp and rainy."

"CHAP. 115.—*How to lay grounds of gesso grosso on the surface of a picture with a spatula* (1).

"Where the panel is very dry, take the point of a knife like a rasp (*mello*), rasp it well, and make the surface quite even. Then take some gesso grosso, that is to say, volteranno, purified, and sifted like flour. Put a porringer full on the porphyry slab, grind it well with this glue, as you would grind colours, collect it, and put it on the surface of the pictures, and, with a very smooth and rather large spatula, cover the whole surface, and wherever you can use the spatula do so.

"Then take some of this ground plaster (gesso), warm it, take a soft hog's-hair pencil, and give a coat on the cornices and foliage, and on the even surfaces with the spatula. Give three or four coats on the other parts of the cornices, but on the other level parts you cannot use too much. Leave it to dry for two or three days. Then take the iron rasp (*mesella*) (2), and level the surface; procure some small iron rods, which are called raffiette, such as you will find in the painter's, who use several kinds of them. Pick out all the cornices and foliage which are not flat, and with these make every part of the surface of the ground smooth and free from knots."

"CHAP. 116.—*How to prepare a fine ground* (*gesso sottile*) *for pictures.*

"You must now prepare a plaster for fine grounds, called gesso sottile. This is made from the same plaster as the last, but it must be well washed (*purgata*), and kept moist in a large tub for at least a month; stir it up well every day until it almost rots (*marcise*), and is completely slacked, and it will become as soft as silk. Throw away the water, make it into cakes, and let it dry; and this plaster (*gesso*) is sold by the apothecaries to our painters. It is

used for grounds for gilding, for working in relief, and other fine works."

"CHAP. 117.—*How to prepare a ground of gesso sottile on a picture, and how it is to be tempered.*

"Having laid on the gesso grosso, rubbed down the surface, and polished it well and delicately, put some cakes of the gesso sottile into a pipkin of water, and let them absorb as much as they will. Put a small portion of it at a time on the porphyry slab, and, without adding any water to it, grind it to an impalpable powder. Put it then on a piece of linen cloth, strong and white. When you have ground as much of it as you want (for you must consider what quantity you will want that you may neither have to make two portions of tempered plaster, nor to throw away any good plaster), take some of the same glue with which you tempered the gesso grosso. You must make sufficient at one time to temper both kinds of gesso. The gesso sottile requires less tempering than the gesso grosso; the reason for this is that the gesso grosso is the foundation of all your work, and that how much soever you press the gesso grosso a little water will still remain in it. For this reason make the same kind of glue for both. Take a new pipkin which is free from grease, and if it be glazed so much the better. Take a cake of this gesso sottile, and scrape it fine with a knife, as you would cheese, and put it into the pipkin. Put some of the glue on it, and stir the gesso as you would a paste for making fritters, smoothly and evenly, until there are no longer any lumps. Procure a cauldron of water, and make it very hot, and put into it the pipkin containing the tempered gesso. Thus the gesso will become warm, but will not boil; for if it should boil, it would be spoiled. When it is warm, take your picture, and a large and very soft pencil of hog's bristles, dipped in the pipkin, and taking up a proper quantity at a time, neither too much nor too little, spread it evenly over the level surfaces, the cornices, and the foliage. It is true that in doing this the first time you should spread and rub the gesso with your fingers, and hand, wherever you can, and this will incorporate the gesso grosso with the gesso sottile. When you have done this, begin again, and spread it with the brush, without touching it with the hand. Let it rest a little, but not so long as to dry thoroughly; then pass over it a third time with the brush, and let it dry as usual. Then give it a coat on the other side; and in this manner, always keeping gesso warm, give the panels eight coats. Foliage and *relievos* require less, but you cannot put too much on cloths. This is on account of the rasping or rubbing down, which is done afterwards."

"CHAP. 120.—*How to begin to smooth the surface of a panel on which you have laid a ground of 'gesso sottile.'*

"When you have finished laying the ground (which must be done in one day, even if you work at it in the night, in order to complete it in the usual way), let it dry in the shade for two days and nights at least. The drier it is the better.

"Tie some powdered charcoal in a piece of linen, and sift it over the ground of the picture. Then, with the feather of a hen or goose, spread this black powder equally over the ground, because the panel cannot be made too smooth, and because the iron with which you rub the picture is smooth also. When you remove it, the ground will be as white as milk, and you will then see whether it requires more rubbing with the iron."

"CHAP. 121.—*How to plane surfaces on which 'gesso sottile' has been laid, and of what use the planing is.*

"Take a flat raffieto, about as wide as a finger, and gently rub the surface of the cornice once; then, with a sharp rasp (*mella arrotata*), which you must hold as freely and lightly as you possibly can, rub over the surface of the panel with a very light hand, brushing away the loose gesso with the feather. And know that this dust is excellent for removing grease from the pages of books (*carte de libri*).

"In the same manner rub smooth the cornices and foliage, and polish them as if they were ivory. And sometimes (for you may have many kinds of work) you may polish cornices and foliage by rubbing them with a piece of linen, first wetted and then squeezed almost dry."

The bands of old linen evidently serve the purpose of the sand in the Egyptian method. They afford a tooth for the plaster, and at the same time must help to hold the panel together, and also help to prevent soap or resin rising through the gesso surface. Apparently linen was also used for the best coffins in Egypt in the same way.

The Gesso Volterrano is, according to Mrs. Merrifield, plaster of Paris, which was obtained from some gypsum quarries in the neighbourhood of Bologna, and Vasari gives a long account of this Gesso Volterrano in his life of Andrea Verrocchio, who used it to make casts of dead persons.

It will be noted that the gypsum for the final coating of gesso is thoroughly slaked by keeping in water for some weeks.

A very fine example of gesso work exists in the old cathedral church at Coire. They have there a box which they claim to be as old as the ninth century. It is entirely covered with gesso, on which a design in low relief has been roughly scrolled. The gesso has been polished so as to give the appearance of ivory. At the corners, where it has got chipped off,

the ends of the linen can be seen, which has evidently been put next the wood, as Cennino Cennini advises. There is nothing, I think, in the whole of this account which could not be easily reproduced at the present day. I have here a mahogany panel which has been prepared by a picture frame-maker, from Cennino's directions.

Gilding.

Having completed the preparation of the panel, we can now paint upon it, or, as was usually done in the earlier Italian pictures, cover it completely with gold leaf.

For this purpose Cennino Cennini mentions three mordants that can be used; one prepared from white of egg and Armenian bole, one a quick-drying oil varnish similar to the gold size now used, and one prepared from garlic juice. He devotes some space to the account of gilding done with the white of egg medium, which I shall quote in full. The only trace of this method of gilding left now is the use of white of egg by bookbinders in gilding books. The bole is used in water-gilding now with parchment glue.

"Chap. 131.—*How to lay bole on panels, and how to temper it* (1).

"Let us return to our subject. When you have finished the relievos of your picture, procure some Armenian bole and try whether it be good. Touch your under lip with it; if it stick to it, it is good. You must now learn the best tempera for gilding. Put the white of an egg into a very clean glazed porringer. Make some twigs of broom into a rod, and beat up the white of egg with it until the porringer is full of thick froth, which appears like snow. Then take a common drinking-glass, not too large nor too full of water, pour it on the white of egg into the porringer. Let it stand from night till the next morning, to clarify itself. Then grind the bole in this tempera as perfectly as you can. Next dip a clean soft sponge into clean water, and squeeze it dry; rub lightly with the sponge (not too wet) on these parts, on which the gold is to be laid. Then pass over it, for the first time, with a large pencil of minever, a coat of this tempered bole as liquid as water, and, wherever the gold is to be used (having first sponged the part with water), spread the bole very evenly, being careful not to stop, so that you may leave no hard edges with your pencil. Then wait a little; put a little more bole into your porringer, and let the second coat of colour have a little more body. Give it this second coat, and let it again rest a short time; put more bole into the vase, and give it a third coat in the same manner; making no hard edges. Put more bole still in the vase, and give it a fourth coat, and then you will have finished laying on the bole. Now you may cover over your panel with a cloth, to keep it as much as you can from dust, sun, and water.

"Chap. 134.—*How to gild panels.*

"When the weather becomes damp and cloudy, and you wish to lay on any gold, place your panel flat on two trussels. Sweep it with a feather, and, with a raffietto, pass very lightly over the ground of bole, and if you find any knots or roughness remove them. Burnish the bole very carefully with a piece of coarse linen. If you afterwards burnish it with a tooth, it cannot look otherwise than well. When you have thus cleaned and burnished it, put into a glass nearly full of clean water a little of the white of egg tempera; if it be quite fresh so much the better. Mix it thoroughly with the water. Take a large pencil of minever, made, as I have previously taught you, of the hairs of the tip of the tail. Take up your fine gold with a pair of fine pincers, lay it on a square piece of card larger than the piece of gold, and turned up at each corner, which you are to hold in your left hand, and, with the pencil which you hold in your right hand, wet the hole sufficiently to hold the piece of gold you have in your hand. Wet the hole equally, that there may not be more water on one part than on another; then let the gold slip off the card, taking care not to wet the card. Now, as soon as the gold has touched the wet part, withdraw the card quickly and suddenly; and if you perceive that the gold does not adhere to the panel, press it down as gently as you can with a piece of clean cotton, and in this manner gild the other parts of the panel; and when you wet it, preparatory to laying on the second piece of gold, be careful that the pencil does not go so near the first piece as to make it wet; and let the two pieces join, first breathing on it, that the gold may adhere where you wish it to unite with the other piece. When you have laid on three pieces, pass the cotton again over the first piece, and see whether any part requires mending. Provide a cushion as large as a brick, made of a smooth piece of board, covered with soft leather, very clean and not greasy, of the same kind as that of which boots are made. Stretch it very evenly, and fill the space between the wood and the leather with shreds of cloth; spread a piece of gold evenly on this cushion, and with a knife cut the gold into pieces as you want it, to make the necessary repairs. Wet the parts to be repaired with a minever pencil, and then, wetting the handle of the pencil with your lips, the piece of gold will adhere to it sufficiently to enable you to apply it on the part to be mended. When you have laid as much gold on the level surface as you can burnish in one day (for which I shall give you directions when you have to gild cornices and foliage), be careful to collect the small pieces of gold, as those masters do who are economical, so that you may save the gold as much as you can, being sparing of it, and always covering the gold you have laid on with a clean handkerchief."

"CHAP. 135.—*What stones are proper for burnishing gold.*

"When you mean to burnish gold, you must procure a stone called lapis amatisto, which I will show you how to prepare. If you have not this stone, sapphires, emeralds, balas rubies, topases, rubies, and granite, are still better for those who can afford the expense, and the finer the stone, the better it is for the purpose. The teeth of dogs, lions, wolves, cats, leopards, and generally of all carnivorous animals, are equally good."

"CHAP. 137.—*How to burnish gold, and what to do if you cannot burnish it when ready for burnishing.*

"You must now burnish gold; for the time is come that you should do so. It is true that, in winter, you may gild whenever you please, during damp and cloudy weather. In summer it will take one hour to lay on the gold; another to burnish it; but should the weather be too damp, and, from some cause or other, you are unable to burnish it, keep it in a place where it is exposed to heat and air; but if it be too dry, keep it in a damp place, always covered, and, when you would burnish it, uncover it carefully, for the smallest scratch will blemish it. Put it in a cellar, at the foot of the casks, and it will be ready to burnish; but, should you be prevented from burnishing it for eight or ten days or a month, take a very clean handkerchief or a towel, lay it over your gold in the cellar, or wherever it may be; then take another handkerchief, dip it in clean water, wring, and squeeze it very dry; open it, and spread over the first handkerchief that you laid over the gold, and the gold will then be in a proper state for burnishing."

We have here a complete account of gilding with white of egg. Further on, he gives the following recipe for another mordant:—

"A perfect mordant for walls, pictures, glass, iron, and every other thing may be made as follows: With your oil either boiled on the fire or baked in the sun in the manner before directed, grind a little biacca (white lead) and verdigris; and when you have made it flow like water, add a little varnish and boil altogether for a short time."

The varnish mentioned here is probably an oil varnish, as the varnishes described at that time are all oil varnishes. The verdigris would make it dry very quickly, and, consequently, he directs later on that no verdigris is to be added if it is not to be used at once. He also states that some fear the verdigris injuring the gold, but he has not found it do so. The rest of the directions are the same as those now given for gilding. It is of interest to note that, though he especially says the leaf must be thick for the white-of-egg gilding, he recommends very thin leaf for this gilding.

For miniature work he recommends the use of a little *gesso sottile* (one-third) mixed with a little white lead and sugar of "candia." This is made into cakes and dried in the shade. This is ground with white of egg for use. "And you must know that you may write letters with a pen dipped in this size." In another recipe he adds also a little Armenian bole.

Prof. Middleton has an illuminated MS. of the 16th century, in some parts of which the gold has come off. Underneath is a hard polished substance raised above the level of the parchment. Apparently in this case Armenian bole must have been used. Besides gold leaf, silver leaf, and tin leaf, were used. Tin leaf is recommended as superior to silver leaf, as it does not blacken. Cennino Cennini recommends the use of the tin leaf for glories of saints in wall paintings. His directions are a little obscure, but apparently it is stuck on with varnish. He also recommends gilding it before sticking it up.

This use of tinfoil is of special interest. At a later date it seems to have been used largely instead of gold, being coated with a yellow varnish called auripetrum. Several recipes for auripetrums are given in the old MSS. The Spanish leather hangings which are so famous have been prepared this way. I examined some portions of some old hangings in the possession of Mr. Cobbold, of Felixstow, and found that a design had been stamped on the leather, then it had been covered with tin leaf. Some parts of the tin leaf had been varnished with a yellow varnish and other parts painted. The rich bronze gold colour being so produced. The hanging shown has been prepared by coating canvas with size, then with gold size, and then with tinfoil. The tinfoil has then been polished and varnished with an oil varnish coloured with dragon's blood.

The recipes for the preparation of auripetrum are somewhat obscure. Several are given in the MS. of St. Andemar, which has been translated by Mrs. Merrifield. In these the oil varnish used is coloured by saffron, aloes, the inner bark of black plum, or dragon's blood. These substances are all easily dissolved in melted pine balsam, which can then be diluted with boiled oil and turps.

The re-introduction of varnished tinfoil for decorative work is, I think, to be recommended. Very beautiful and durable results are, I think, easily obtained.

Dragon's blood is easily obtainable, but varies very much in quality; the best that can be *now* obtained being sent over in sticks

about 8 inches long, each stick being encased in some native fibre. The dragon's blood in lump, as usually sold, is very inferior. The dragon's tears referred to by Charles Reade, in his essay on violins, are unfortunately no longer to be had. I know of only one sample in a herbalist's window in East London, and it is not for sale.

There is no great difficulty in having panels prepared for painting according to the method herein described, as the practices of the best gilders approach very closely to Cennino Cennini's recipes. It is perhaps not generally known that gold leaf is translucent, and that the light passing through is blue green in colour. The laying of gold on white gesso on the ground for the picture must, I think, have have had an important effect on pigments above it, corresponding to a green ground to a certain extent. Having described the preparation of the panel, we shall consider in the next lecture the preparation and properties of the pigments used to paint upon it.

Miscellaneous.

NOTES AND HINTS ON THE VEGETABLE PRODUCTS OF TROPICAL AFRICA.

By John R. Jackson.

[Concluded from page 122.]

Gums and Resins.

These may be divided into two distinct kinds, namely, the true gums which are soluble in water and form mucilage, like the Acacia gums or gum Arabic, and the hard or semifossil gums or resins, which are valuable for varnish making. The soluble gums must be looked for on the trees as they stand, and any species of Acacia may be expected to yield a soluble useful gum. Gums from different trees should not be mixed, as one kind may be of inferior quality to another, and consequently diminish the value of the better kinds. Botanical specimens should accompany these gums when sending them for report. Hard gums, or semifossil resins, are commercially known as Copal, and the very best, which is a product of Zanzibar, as Anime. This fetches the highest price of any in the European markets, and any resin approaching it in appearance should be eagerly looked after. Most of the Copals which come from the west coast of Africa are from leguminous trees, namely species of *Copaifera*, therefore allied plants should be specially looked for. All these hard resins are found buried in the ground, at varying depths, sometimes in the neighbourhood of existing trees, and sometimes on the sites of extinct forests. As illustrations of comparatively new sources from the African continent may be mentioned two recent discoveries, both in the year 1883: the first at Inhambane, where a "tract of copal forest, fully 200 miles long," was revealed, and samples of the copal, or anime, sent to England, and valued at from £80 to £100 per ton. It is known as Inhambane copal, and is the produce of *Copaifera gorskiana*. Another gum resin, known as "Ogea" gum, from the Gold Coast, was introduced to notice in the same year (1883). It is said by the natives to be used for lighting fires, and for illuminating purposes, and also as a body perfume by the women. It exudes from the trunks, either from wounds or holes caused by the boring of insects. The plant furnishing this resin is not definitely known, though it is clearly leguminous, and is probably closely allied to *Daniellia thurifera*.

Dyes and Tanning Materials.

Though the demand for vegetable dyes has, of late years, considerably decreased, in consequence of the very wide application of the coal-tar dyes, there is still a considerable amount of interest attached to new sources. Indigo is of all dyes of vegetable origin the most important. True indigo is obtained by macerating the leaves of species of *Indigofera*, chiefly *I. tinctoria* and *I. anil*, and evaporating the fluid to a thick consistence. These plants are largely cultivated in India and South America, and they are also grown in tropical Africa.

The native Yoruba indigo is obtained from a distinct plant (*Lonchocarpus cyanescens*), belonging to the same natural order. Though this dye is used in its native country, it has never been thoroughly experimented upon in England, though it might prove worth importing here as a new source of indigo.

Amongst yellow dyes to which more attention should be given than they have yet received may be mentioned the "Doundake" (*Sarcocephalus esculentus*), and the yellow dye-plant of the Soudan (*Cochlospermum tinctoria*).

It is difficult to indicate any particular natural orders of plants that are likely to yield colouring matters, as dyeing substances are found not only in widely-different natural orders, but also in different parts of the plant, as in the stems, roots, &c., and the same may be said with regard to tanning materials, though this principle is mostly found in barks and roots, and any such known to contain astringent properties should be tried for their suitability for tanning leather.

Fibres.

There is a very wide field open for the development of fibrous substances, whether for textile purposes, for rope and cordage, for brush-making, or even for paper stock. For weaving, the fibres must be very fine, continuous, and strong, and no better example of a suitable textile can be had than the flax (*Linum usitatissimum*) which, from its very

slender stem, furnishes a fibre held in the highest repute in the earliest period of the world's history, and still occupying a similar prominent place amongst the large number of fibres at present known to the commerce of the world. A very large number of tropical plants yield a fine but strong and tenacious fibre from their stems, and such must be looked for chiefly amongst plants belonging to certain natural orders as, for instance, the mallow family (Malvaceæ), sterculia family (Sterculiaceæ), lime tree family (Tiliaceæ), nettle family (Urticaceæ). Besides these there are many plants belonging to widely different natural orders which have very valuable fibrous inner barks. The presence of fibre in the barks or stems of any plant suspected of possessing it may easily be detected by cutting or breaking a piece of the stem across, and such as show a fibre should be carefully collected in sufficient quantity, say a couple of dozen pounds or so for an examination and trial at home. Again, there are many plants, such as those belonging to the pine-apple and the lily families—species of *sansevieria*, known generally as bowstring hemp, which contain valuable fibres (for rope and cordage making) in their leaves. These should command the same careful attention as those before referred to. Quite recently attention has been directed by the Governor of Lagos to a substance of which but little has hitherto been known, but which has been designated as Lagos bass. It consists of the fibres drawn from the petioles or leaf stalks of the so-called bamboo palm of West Africa (*Raphia vinifera*). This material seems likely to become an important article of trade for brush making, as a substitute for, or mixing with the true bass or piassaba from Brazil or Bahia, which of late years has been getting scarce, and consequently fetching higher prices.

A fibre that was brought to notice so recently as 1889, also by the Governor of Lagos, has been reported upon very favourably by Messrs Ide and Christy, of Mark-lane. It is known under the name of "Bolobolo" and in the Yoruba language as "Agbonrin Ilassa;" the plant from which it is obtained is *Honckenya ficifolia*, belonging to the natural order Tiliaceæ. The following quotation from the report on this fibre, by the firm just alluded to, will be of interest:—"If this fibre is capable of being produced in large quantities, there is a very wide field open to it commercially. Its market value would be regulated by that of jute, but, in our opinion, it would always command a higher price. At to-day's currencies it would sell at £16 per ton in London. We do not think the minimum price would ever fall below £12; and if the jute market made a further advance, this Bolobolo fibre might realise £20. If this fibre could be prepared of a whiter colour, it would prove still more acceptable, but even as it is, we should be very glad to see large quantities placed on this market, where they would sell readily."

Woods.

Woods may be divided into three chief divisions—namely, those useful for building or structural purposes, those used for ornamental or cabinet work, and hard woods used for turning, and particularly for wood-engraving. It can scarcely be expected that timbers or building woods can ever be brought to this country to return a sufficient profit, even if forests of any particular timber were to be opened out; it might, however, be worth transferring to other places not so far afield. With ornamental or cabinet woods, however, the case is different, for such woods, if showing any remarkable figure or colour, could be cut into thin veneers by European wood merchants, and if the trees furnishing the wood were known to exist in sufficient abundance to meet any demand that might arise, a trade might be at once established. The same may be said with regard to hard woods, and especial attention should be given to any close, even-grained wood of the character of box, the demand for which, for wood-engraving, is now so great and the supplies, comparatively speaking, so small, that it has been for some time realising a very high price. It is difficult to point to any direction where valuable woods of the character here described are to be found; but sections of any trees of a good diameter, which seem likely to produce valuable woods, should be obtained, and sent to some well known hard-wood dealer for report. Some of the best known woods of west tropical Africa is the mahogany, so-called, of the Gambia, furnished by *Khaya senegalensis*, a meliaceous tree closely allied to the true mahogany. African rosewood, from *Pterocarpus erinaceus*, and the odoom, Roko or Iroko, a wood of a bright yellow colour, furnished by *Chlorophora excelsa*, a tree closely allied to the West Indian fustic. So little is known, generally, of West African woods, or of their scientific sources, that it is most necessary that specimens of the foliage, flower, and fruit should be gathered from each tree from which the section is taken, for the proper botanical determination of the tree.

Perfumes, or Fragrant Substances.

Under this head, it is almost impossible to signalise any particular plants, or to point to any one or more natural families to which special attention should be paid. The leaves, flowers, fruits, or even seeds of some plants, possess a fragrant principle; and they have the advantage of attracting attention by the odour emitted, so that they will not fail to command notice. In whatever part of the plant the perfume resides, care should be taken to thoroughly dry that part before packing to send home, else damp and mildew may make it thoroughly worthless before it arrives.

Materials for Walking-sticks.

As this trade has now become a very large and important British industry there is necessarily a great and increasing demand for materials, such for instance as young Palm saplings, with good roots to

form the knobs or handles, or any woody plant that may exhibit an ornamental or characteristic bark. It is not necessary that the stems should be in all cases long enough for an ordinary walking-stick if the rooting portion has sufficient character to recommend it, for one of the arts of the walking-stick and umbrella-handle maker is to graft or join an ornamental knob or root on to a plain but rigid stick. Nor is it necessary for the stick to be straight, for some of the most crooked sticks are effectually straightened by heat. A few should be sent home for report, and to try whether they have any market value.

THE TOBACCO INDUSTRY OF PERSIA.

Among Persian products, tobacco holds a most prominent and important position, whether viewed from an industrial and commercial, or a social and political standpoint. The United States Consul-General at Teheran says that in its cultivation and preparation for market and transport to inland and seaport towns, large numbers of people and animals are employed. It is one of Persia's principal commodities of export, and supplies to a certain extent the bazaars of Turkey, Arabia, Egypt, the Caucasus, and Central Asia, whilst from the taxes levied upon it in the shape of customs, transit dues, and plantation tithes, the Government realizes a considerable revenue. The place occupied by tobacco in the estimation of Persia is altogether different to that assigned to it in Europe and America. In Persia it is removed from the sphere of luxuries, and held as one of the principal articles of daily necessity. An increase or reduction in the price of tobacco affects, for good or evil, almost every man, woman, or child in the kingdom. A failure of the tobacco crop would be considered as little less than a national calamity, and any cause which has the effect of raising the price of tobacco diminishes to a very considerable degree the power to purchase the actual necessaries of life. In the cultivation of the land intended for the reception of the seed great care and pains are taken to render it as suitable as possible for the germination of the seed and the gradual growth of the plant. A steady and ample supply of water is one of the most essential things in the successful cultivation of tobacco. Upon the quality of water depends also to a certain extent the delicate flavour and aroma of the leaf and its price in the market. If the water is distinctly brackish the tobacco will be mild or sweet, and its value as a commercial commodity greatly increased. If, on the contrary, the water is sweet and the soil unduly free from salacious elements, the tobacco will be rank to the taste and the odour unpleasant, and consequently of an inferior quality. The fertilizer generally used is a mixture of ashes and pigeon's dung. In order to procure an abundant supply of the latter, numerous large mud towers, having walls extensively perforated with holes large enough for the bird to roost, lay its eggs, hatch, and bring up its young in, are built on the outskirts of towns and villages and on the tobacco plantations. The seed is sown from March 1 until April 5, and this is done on prepared beds of soft mould sprinkled over with a layer of fine sand. After sowing, the seeds are lightly covered with fine sand and regularly watered every five days, until about June 1, when the plants have attained sufficient strength and maturity to admit of being transplanted. This being done, the fields are divided into squares with slightly raised embankments, and flooded. In some places it is customary, when the plant is about half grown, to make an incision in the stem, and insert one or two spikes of dried clover into the internal cavity. From these it is supposed the sap extracts a certain amount of flavour, which becomes absorbed into all the structural parts, and adds a pleasant, spicy aroma to its smoking. As soon as the plants arrive at maturity, which is usually about the end of August or the beginning of September, the harvest commences. If the leaves, after attaining a certain degree of perfection, are allowed to remain on the parent stem, they begin to change their colour, and are quickly spoiled. In order, therefore, to avoid loss, and give the plant time to develop the upper or younger leaves, the lower or first formed are gathered first. The petiole or stalk stem is carefully severed, and the leaves are laid on the ground and left in the field to get partially dried by the sun until they have changed from a green to a golden hue. As one cutting of leaves becomes sufficiently dry it is taken home, and another is proceeded with in the same manner until the whole is harvested, and nothing remains in the field but such plants as are left for seed. The process of drying or curing and preparing the article for market has to be continued without interruption and with vigilant care if the delicate flavour and fragrance of the leaf are to be retained. The leaves are hung up in every available space, and turned and re-turned with the greatest regularity. Whilst this operation is going on, such of the tobacco as has been grown with slight admixtures of alkalis is sprinkled with a weak brine, to give a pungency and flavour in the smoking, and also to preserve it from becoming musty. The tobacco is packed and pressed into sacks of coarse canvass, containing from twenty to eighty pounds each. An outer covering of the same material, to protect the tobacco as much as possible from the deteriorating effects of the air, is also added, and the whole is encased in coarsely tanned goat skins. The quality of the tobacco depends upon the locality in which it is grown, the best being that which is produced in the neighbourhood of Sheeraz and Tabaz, and the most inferior at Kashan. A large proportion of the Ispahan crop is shipped to Egypt and the Levant, as it is considered too hot or pungent for home consumption. There are three different sorts of tobacco produced in Persia. The first, called *tombakoo*, grown in Sheeraz, Ispahan, Kashan, Yezd, Tabaz, Semnan, Neharend, and Khorassan, is used only for the *kalean* or nargile, and supplies the

largest portion of the export trade. The second, called *tuttoon*, grown in Koordistan, Kermanshah, Ooroomeeyah, and other parts of Azerbaijan, is used solely for the chibouk, and is also exported in considerable quantities to Arabia, Asia Minor, and the Caucasus. The third, called cigarette tobacco—grown originally from Turkish seed, in the provinces of Ghilan and Mazanderan, on the southern littoral of the Caspian Sea—is used, as its name implies, for making cigarettes, and is, with the exception of what is consumed in Persia, exported entirely to Russia. There is also another variety, though it does not enter into commerce, grown in the vicinity of Sheeraz, and known as *duckhter peech, i.e.*, "the maiden's plait or curl," a name derived either from the resemblance of its prepared rolls to a young girl's braided hair, or because the hands of maidens are alone considered suitable to gather its delicate leaves. Tobacco, as an article of export, is found to occupy the third place in importance of the productions, both natural and manufactured, of the whole of the country. The order would be—rice first, opium second, and tobacco third. Consul Pratt says that it is his earnest conviction that not only can the cultivation and manufacture of tobacco in Persia be immensely increased, but new varieties of the plant might be successfully introduced into the country, and made to produce the most profitable results.

FARMING IN JAMAICA.

It is believed that Jamaica offers favourable openings for young men from Great Britain and other European countries with small capitals (say of from £2,000 to £3,000) and some experience in farming, who wish to adopt an agricultural career. The Governors of the Institute of Jamaica have therefore come to the conclusion that it is desirable to take some steps to bring about a means of communication between those planters and penkeepers who are willing to receive young men as articled pupils, and intending emigrants from Great Britain and elsewhere.

They have prepared a register of such planters and penkeepers as are willing to take pupils; but it must be distinctly understood that they can accept no responsibility at all in the matter, and can only circulate copies of the *précis* of the replies received from planters, from which inquirers must draw their own deductions. A form of agreement which, it is thought, might prove of service, has been prepared, but the use of it is, of course, optional.

Pupils must also communicate direct with the planters and penkeepers with respect to terms, &c.; and it is suggested that some friend should, if possible, be asked to visit the property on behalf of the pupils.

A schedule, which has been compiled from the replies (alluded to above) hitherto received from the planters and penkeepers, shows (1) the nature of the properties; (2) the districts in which they are situated: (3) the premium required; (4) some indication of the kind of home and surroundings the pupils might expect; and (5) the work they would have to perform, and the instruction they would receive. Copies of this schedule can be obtained on application to the Secretary of the Jamaica Institute Kingston, Jamaica, who will be pleased to hear from any planters or penkeepers who wish to have their names added to the register.

THE USES OF BURNT-CLAY MORTAR IN ITALY.

The United States Consul at Catania, in his last report, says that visitors to Catania invariably notice and remark on the peculiar soft pink colour of all the unpainted buildings. This colouring is the result of using cement or mortar of proved value, found in the vicinity, and which is nothing more or less than burnt clay. In the frequent eruptions of Mount Etna in times past, great beds of clay were covered and buried from twenty to two hundred feet by the lava streams, with the result, when the eruption happened in the dry season, of burning and converting these clay beds into a fine red gravel or powder. These deposits are mined, and are considered very valuable. The material, mixed with a little lime and the usual amount of water, forms a mortar or cement considered superior to any other cement for building purposes, and has been used in Catania to the exclusion of all other materials for many centuries. Every building in Catania is constructed of lava liberally cemented with this mortar. In building, small irregular stones are used, just as they happen to come, and a smooth surface is afterwards given by a thin coating of mortar inside and out, which can then be divided by a trowel to imitate blocks of stone, if desired. This burnt clay, with lime, makes a very strong and adhesive mortar; no other material would hold together the large four and six storey apartment houses, which are built entirely of small irregular stones. It also has unequalled wearing and resisting power, as the extensive harbour breakwater proves. This breakwater was built some ten years ago, and extends for three quarters of a mile out into the sea, and is said to be as good to-day as when first built. It is composed entirely of lava, and for a foot below watermark to a sufficient height to protect the shipping, of huge blocks of small lava rubble liberally cemented with the mortar. The constant wear and tear of the sea for ten years has only damaged the cement in insignificant places, and probably only where there happened to be an air space between the mortar and stones caused by faulty construction of the blocks. Consul Heath adds that the more he looks into the matter the more he is convinced of the value of this mortar as an economical substitute for all the high-priced hydraulic cements now used, and might well be adopted in other countries besides Italy.

INDIAN LAPIDARIES.

There are about 100 merchants at Cambay, India, who deal in agates, and from 2,500 to 3,000 artisans are employed there, the annual outturn ranging from £2,000 to £3,000. They make paper-cutters, armlets, jewellery boxes, and other articles of green moss-stone, white agate, and of bloodstone of red and pinkish colour. Paper-weights and rulers are made of the famous Trichinopoly marble, which is of a bluish-grey colour, hard, and takes an excellent polish. It is a cretaceous rock, consisting chiefly of well-preserved specimens of shells, with sometimes pebbles and fragments of fossil wood.

In Agra, paper-weights, knife handles, &c., are made of agate, jasper, and onyx. Plates, small boxes, paper-weights, and inkstands are made of soapstone. The manufacture of ornamental work in soapstone has been in vogue in Agra for over 30 years, and the delicacy of the carving and the beauty of the patterns have acquired for its products a very wide popularity.

The same workmen who prepare this well-known inlaid marble work are employed in the carving of soapstone articles. The lapidaries of Bhira, in the Punjab, make the hilt or handle of knives and whips, caskets, and paper-weights of the false jade or serpentine. This green, jade-like stone has not yet been assigned its proper name. It is not true jade, being much softer than that of Silesia or China; nor do authorities on the subject admit it to be plasma. It is said to be found near Kandahar, and to be brought down the river Indus on rafts, floated with inflated skins, to Attock, where it is carried to Bhira. Other stones, resembling serpentine and purbeck marble, are used as handles, and also in the fashioning of toys and small objects, such as paper-weights, by the lapidary cutlers of Bhera. There are valuable quarries near Balasore, in India, from which a description of chlorite, or black marble, is obtained, from which plates, dishes, cups, and other household utensils are made. These fetch high prices, and are much sought after.

WOOL GROWING IN ALEPPO.

Sheep are reared in very considerable numbers in the vilayet of Aleppo, and the district of Aleppo, or, more properly speaking, the mutessarrifiates of Orfa and Deir-el-Zor, are the localities where the raising of sheep and growing of wool acquire the greatest importance. In the colder districts of Marash, Aintab, Antioch, Kellis, Harem, Djesser-el-Shogr, Idlep, &c., sheep are kept in caves during the winter, and are fed on a mixture of hay and straw. The number of sheep which usually compose a flock varies greatly. Each family forms out of the sheep they possess one or more flocks, watched over by members of the family. Eighty to a hundred sheep are generally confided to one person. The United States Consul at Beyrout says, that the total number of sheep which graze in the vilayet of Aleppo is estimated by the provincial authorities at 2,500,000 in round numbers, divided amongst various tribes. All the sheep raised by these tribes belong to the breed called *Awas*, originally from Bagdad, which in crossing with other races have lost the original fineness, but gained in the length of their wool. The best wools, as regards fineness, are those coming from sheep raised by the tribes called El-Tayawi and El-Neim, who take greater care of their flocks, and give them, two months after the shearing, and several weeks apart, two or three sulphur baths, and also administer to them small doses of sulphur internally. By this treatment the sheep appear to enjoy immunity from the skin diseases which influence the beauty of the wool. Next to the wool grown by these two tribes, which is limited in quantity, comes that of the Hadidi. The process of shearing in Aleppo is of the simplest order. The sheep is laid on the ground and is shorn with common shears. This takes place from the end of April to the end of May. Each fleece is rolled up separately and is sold to the tradesmen from Aleppo, Orfa, and other localities of minor importance, who visit the encampments of the Arabs on the outskirts of the desert, where the bargains are made. The fleeces are not sold by weight but by the piece. Wool thus bought is transported to the various inland cities on camel back, and then sold to merchants and exporters. It is these latter who occupy themselves with the cleaning of the wool and with its packing in bales by hand presses. The washing of the wool is also performed by the exporter. After removing the dirt, each fleece is washed separately in a current of water. After washing, the fleeces are spread out on the grass or on stony ground and exposed to the sun. The wool from the Aleppo vilayet is mostly exported, either washed or unwashed, to the United States and to Europe, a large portion going to Marseilles. The wool from slaughtered sheep is spun by hand on common spindles, and is made into *abas*, a sort of coarse thick woollen cloak with a hood. The manufacture of these *abas*, which are used to a considerable extent in the neighbourhood is of the most primitive kind—on the old hand looms, without the employment of any mechanical contrivances. Wool is also to some extent made into carpets in this province. The wools grown in the vilayet of Aleppo are divided into seven principal classes—(1) the wool called *Hadidi*, which embraces not only the wool grown on sheep raised by this tribe, but comprises also all that produced by other tribes; (2) the wool called *Anezi*; (3) *Deir-el-Zor*; (4) *Fellahi*. These four categories are sold in the city of Aleppo, and three of them are known in Marseilles under the name of "unwashed Persian wool," the fourth, or *Fellahi*, being designated as "red Persian unwashed." When washed, they are known under the commercial name of "Aleppo washed wools." Classes 5, 6, and 7 are called respectively *Arabi*, *Barazi*, and *Milli*. The latter is by far the coarsest of these seven cate-

gories, while *Arabi* is superior even to *Hadidi*, and is known in the Marseilles market under the denomination of "unwashed Orfa." All three grades are usually to be found warehoused in the city of Orfa. Besides the varieties enumerated, wools coming from the Mardin district are also sold in the markets of Aleppo. They comprise three qualities, viz., the *Awas*, the *Caracash*, and the *Kurdes*. The first of these three is generally washed on the sheep's back by forcing the sheep to pass once or oftener through a stream of water. The *Caracash* wool is also washed by the same process, only less thoroughly. A very small per-centage of the Aleppo wools is used in the making of *abas* and carpets, and for the filling of mattresses, &c. The quantity of wool annually exported is estimated at nearly 5,000,000 pounds.

Correspondence.

TYPOLOGICAL MUSEUMS.

The following letter from Sir HENRY W. ACLAND, K.C.B., M.D., F.R.S., to Professor Flower, F.R.S., has been received:—

"Oxford,
"Dec. 15, 1891.

"DEAR PROFESSOR FLOWER,

"I greatly regret that it is impossible for me to leave Oxford to-day and attend General Pitt-Rivers's lecture. I had greatly desired to do homage to the incalculable value of General Pitt-Rivers's museum for the purposes of national education in one of its highest aspects.

"As time goes on, this value will be more and more felt. When, in face of fierce opposition, the movement for founding the Oxford museum began about forty years ago, the intention was to add to the resources of the old University an institution where, speaking generally, the facts and laws displaying the unity of the material universe could be illustrated and practically studied.

"In the biological department it was hoped so to illustrate life on our planet that the life history of the vegetable and animal world, past and present, could be studied, in whole and in part, by careful selection of types culminating in man.

"Hopeless, almost, as the task then seemed, the personal character of Phillips and Rolleston cheered it on. General Pitt-Rivers, valuing both these men and their aims, gave an impulse and encouragement which no other man could have given.

"General Pitt-Rivers made possible Rolleston's efforts to unite the study of morphology, physiology, and pathology, with that of psychology and the evolution of the races of man.

"How much this was needed, how deeply interesting the attempt, no one knows better than yourself. Oxford may yet be able through General Pitt-Rivers's museum, displayed, as it is, by the industry and ability of Balfour and the learning of Tylor, to develop a real school of anthropology, in which psychology, language, the development and peculiarities of races, will be philosophically and practically studied.

"There is yet danger that these larger views may be displaced by the present rage for technical education. For the profession of medicine we may still hope that one university may maintain a school for able men who are willing to give time to the scientific study of man, as man, prior to the detailed technical and clinical instruction in the large London hospitals. The great development of the British empire seems to demand that one university should take this position.

"Oxford has still the opportunity. The noble efforts of General Pitt Rivers will have largely contributed to this. His teaching is, in many ways, the bridge between the old and the new schools of thought. We may yet see Max Müller uniting with the modern biblical and historical enquirers, teaching in the museum with Dr. Tylor.—I am, dear Professor Flower, very faithfully yours,

"H. W. ACLAND."

Obituary.

DUKE OF DEVONSHIRE, K.G.—The Duke of Devonshire, who died at Holker-hall on Monday night, 21st inst., had been a member of the Society of Arts for thirty years, being elected in 1861. He was also a Vice-President in 1869 and 1870. His Grace was greatly interested in scientific and social progress. He was elected a Fellow of the Royal Society in 1829, and he acted as Chairman of the important Royal Commission on Scientific Instruction and the Advancement of Science. The Cavendish Laboratory at Cambridge is due to his munificence. He was one of the founders of the Royal Agricultural Society, and its President in 1869. He was also first President of the Iron and Steel Institute. In 1862 he succeeded the late Prince Consort as Chancellor of the University of Cambridge, the University thus honouring one of its most distinguished sons. The particulars of the Duke's life has been so fully recorded in the newspapers, that it is not necessary here to do more than note his connection with some of the chief public institutions of his country.

General Notes.

BULGARIAN EXHIBITION, 1892.—Information has been received from the Foreign-office, through the Science and Art Department, that the date fixed for the opening of the Agricultural Exhibition at Philippopolli, which was announced in the last volume of the *Journal* (November 13, p. 936), has been changed from 6th (18th) September to 2nd (14th) August.

Journal of the Society of Arts.

No. 2,041. Vol. XL.

FRIDAY, JANUARY 1, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CANTOR LECTURES.

The publication of Mr. Laurie's second lecture on "Pigments and Vehicles of the Old Masters" has been unavoidably postponed. It will appear in the next number of the *Journal.*

JUVENILE LECTURES.

The usual short course of lectures adapted for a juvenile audience will be given on Wednesday evenings, January 6 and 13, by Professor John M. Thomson, Sec. C.S., on "Three States of Matter: Solid, Liquid, and Gaseous."

The lectures will commence at seven o'clock. A sufficient number of tickets to fill the room will be issued to members in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each member is entitled to a ticket admitting two children and an adult. Tickets are now in course of distribution, and members requiring them should apply at once.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by members on application to the Secretary.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied post free for 1s. 6d. each, on application to the Secretary.

Chicago Exhibition, 1893.

Under date of the 27th August, 1891, Her Majesty was pleased to issue a Commission to the Council of the Society of Arts, authorising them to act as Commissioners for the Universal Exhibition, which, pursuant to an Act of Congress, and in accordance with a Proclamation made by the President of the United States of America, will be held at Chicago from May 1st to October 30th, 1893.

The Royal Commission are now prepared to receive applications from artists, manufacturers, and others desirous of taking part in the Exhibition, to afford them all necessary information, and to offer them all available facilities which they may desire for this purpose.

Such applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, not later than February 29th, 1892, and addressed to the Secretary, as above.

As the funds granted by H.M. Government will not suffice to defray all the expenses of the Section, it is necessary that they should be supplemented by payments from the exhibitors. A charge will therefore be made to each exhibitor, based on the amount of space occupied, and calculated on the following scale:—

	Per sq. ft. s.	d.
For spaces not exceeding 100 sq. ft. ..	5	0
For spaces exceeding 100 sq. ft. and not exceeding 200 sq. ft.	4	6
For spaces exceeding 200 sq. ft. and not exceeding 300 sq. ft.	4	0
For spaces exceeding 300 sq. ft. and not exceeding 500 sq. ft.	3	6
For spaces exceeding 500 sq. ft. and not exceeding 750 sq. ft.	3	0
For spaces exceeding 750 sq. ft. and upwards	2	6

The minimum charge will be £5.

It is not expected that the total receipts from all sources will more than suffice to defray the cost of an adequate representation of British industry; but should there be a sufficient surplus after the payment of all the costs of the Section, the Royal Commission will refund the balance *pro rata* with the amounts contributed by the several exhibitors. The amount produced by the payments of exhibitors will therefore be

treated as a guarantee fund, to be expended if necessary, but if not, to be refunded to the contributors.

The Exhibition is situated in Jackson-park, within the southern limits of the city of Chicago. The principal buildings are devoted to the following main divisions:—(1) Fine Arts; (2) Manufactures and Liberal Arts; (3) Agriculture; (4) Machinery; (5) Electricity; (6) Mines; (7) Transportation; (8) Horticulture. In all these, space has been allotted to Great Britain, though it is expected that the principal British Court will be that in the Building of Manufactures and Liberal Arts, since the privilege has been conceded to this country of massing all or most of its exhibits together, should such a course prove desirable.

Exhibitors' goods will be transmitted direct in bond to Chicago, where the usual Customs examination will be made. Goods for exhibition only will not be liable to duty, but on goods sold the usual rates will have to be paid. Goods can be sold in bond, at prices independent of the tariff, the duties being payable by the purchaser.

The American railroad companies propose to carry goods back from the Exhibition free, charging the usual rates for the outgoing journey. These rates, it may be noted, are low in comparison with those usual in European countries. It is hoped that special terms for Exhibition goods traffic may be obtained from the Atlantic steamship companies. Full information as to routes, traffic, rates, &c., will be provided in due course.

A general Official Catalogue will be published in English, French, German, and Spanish. A special catalogue will also be published for the British Section.

Exhibitions of live stock will be held, and prizes will be offered in connection with them. A special circular has been issued, giving information about these.

A limited quantity of steam and water power will be supplied gratuitously. Further supplies will be provided at a fixed rate. Countershafts, pulleys, belts, &c., must be provided by the exhibitor. Application for motive power must be made on special forms, which will be supplied on demand.

The general reception of articles at the Exhibition buildings will commence on November, 1892, and no articles will be admitted after April 10, 1893. Foundations for heavy machinery may be put in, and special constructive work commenced, as soon as the state of the grounds and the buildings permits.

Special regulations will be hereafter issued for the organisation of the International Juries.

The Royal Commission are informed that the contract labour laws of the United States will not prevent exhibitors from importing foreign labour, or from entering into binding contracts with their *employés*. Further information on this head will be supplied on application.

Every person who becomes an exhibitor in the British Section thereby agrees to be governed by the rules and regulations laid down by the Exhibition Executive, or by the Royal Commission through its executive officer.

Miscellaneous.

THE TEAK SUPPLY OF SIAM.

The use of teak wood in this country has largely increased of late years, and now when builders and architects have had experience of its durability for the stairs of public buildings, rafters, beams, and such like work, there are fears of a diminution in the supply of the wood. The teak tree extends through Central and South India, Burma, and Siam, and though in the former country the plantations are placed under the careful supervision of the well organised Indian Forest Conservancy, it appears from a report on the trade of Siam, recently furnished to the Foreign Office, that the "number of years which will elapse before the teak forests in the districts become exhausted is variously estimated by the foresters and teak merchants, but twenty years appears to be the longest time allowed, and under present conditions it appears doubtful whether the supply will last so long. In ten years it may not pay to work teak unless prices rise and the method of working is improved upon, as all the timber near the streams will have been felled and dragged, and only those trees will remain which are far removed from the water, or which are near streams from which timber cannot easily be got out." Further than this, it seems that very little is done by the authorities in the way of conservancy of the forests. No young trees are planted, the natural growth of the saplings being relied upon to keep up the supply of teak; but no measures even are taken to protect the saplings from fire or to ensure their growth. Many trees are felled in a green condition, instead of being left girdled for three years until the bark falls off as in Burma.

With these conditions working adversely to the cultivation, or even to the ordinary growth of the tree, the future prospects of the teak in Siam is a gloomy one.

AGRICULTURAL INDUSTRIES OF MEXICO.

Mexico has been estimated to contain 479 square leagues of forests, 18,134 square leagues of mountain land, and 4,822 square leagues of uncultivated land. Extending through seventeen degrees of latitude, eight and a half of which are in the torrid zone, and an equal number in the north temperate zone; and, owing to its physical formation, Mexico has three well-defined climates—hot on the coasts, temperate in the regions lying at an elevation of between 3,000 and 6,000 feet above the sea, and cold in those regions lying at a higher elevation. A recent bulletin issued by the Bureau of the American Republic, says that the vegetable products of Mexico are varied in the extreme, owing to the diversified climate. Its productiveness is perhaps unsurpassed by any other country in the world. The soil produces all the cereals and all the fruits of Europe and the United States. Among the cereals, the most abundant is Indian corn, which grows almost everywhere in the country. This is eminently a Mexican staple, serving as nutriment for man and beast, and forming food for the majority of the inhabitants in the form of cakes, called *tortillas*. What are known as the hot lands (*tierra caliente*), which lie between the coast and the foothills of the Cordilleras, produce the most exuberant vegetation. Excellent grazing lands abound, studded with groups of trees, among which the trumpet-flower tree, and the turpentine, or mastic tree, predominate. Here, also, are found great quantities of gigantic bamboos, known by the name of *tarros*. Nearer the foothills lie immense forests of valuable hard woods, such as mahogany, ebony, rosewood, iron wood, &c. These forests also furnish Campeche and Brazil wood, the rubber tree, and many trees of medicinal value. Hundreds of varieties of plants, herbs, roots, &c., useful in medicine and in the industries, grow in great profusion. There are also, in many parts of the country, a great many kinds of mosses and lichens furnishing excellent dyes, among which the principal is the orchil, which grows in Lower California, and has for many years been an article of large exportation, the Mexican Government deriving large profits therefrom, as there is an export duty of ten dollars a ton. The vanilla plant grows wild in these lands, and sugar-cane is cultivated extensively in the States of Morelos, Vera Cruz, Mexico, Jalisco, Oaxaca, Tabasco, Campeche, Guerrero, and Chiapas. Coffee is grown principally in the States of Chiapas, Vera Cruz, Morelas, Oaxaca, Michoacan, and Colima, and the annual crop is valued at four million dollars. The coffee of Uruapam (Michoacan) is celebrated. Tobacco is a great product of the States of Vera Cruz, Tabasco, Campeche, Yucatan, Oaxaca, Chiapas, and Jalisco. The tobacco crop averages a value of two and a half million dollars. The great cotton-producing region of Mexico is the district of Laguna, in the State of Coahiula, which furnishes over 40,000 bales per annum. Besides this State, cotton grows in Sonora, Chihuahua, Guerrero, and Chiapas, and in several others. The annual crop is valued at nearly eleven million dollars. The cocoa bean is mostly cultivated in Tabasco and Chiapas. The best is grown at Soconusco. Chocolate sells at Soconusco for twenty cents a pound, and an excellent opportunity is said to be offered for the cultivation of the cocoa tree on a large and systematic scale. Soconusco is also the natural home of the rubber tree, but the natives foolishly chopped down and destroyed great numbers of these trees, and thereby retarded what would have become a great industry. A rubber tree once fairly started requires little or no care, and will produce the milk abundantly in from six to eight years from planting. In 1889 the Department of Public Works entered into a contract with three Mexican gentlemen to plant 15,000,000 rubber trees in the State of Oaxaca near the shores of the Pacific. The planting was to begin within eight months from the date of the contract and be finished within fifteen years, 300,000 trees to be planted the first year, and 1,000,000 each subsequent year of the term mentioned. A subsidy of three cents per tree was guaranteed by the Government, and exemption from duties on all necessary materials, tools, &c. The hot lands also yield sarsaparilla, jalap, rice, arrowroot, beans, indigo, and many other products. This region is especially rich in fruit-bearing trees, principally among which may be enumerated the orange, lemon, citron, tamarind, guava, plum, plantain, nut, and banana trees and date palms. Pineapples and melons and many other tropical fruits grow wild. The banana and the orange grow spontaneously in great abundance near the Mexican coasts. The cultivation of the orange is very profitable. One man can cultivate with his own hands from seven to nine acres of orange trees. One tree in the tropic belt of Mexico will yield as many as 5,000 oranges. Sonora is a great orange-raising district, fruit coming from the vicinity of Hermosillo in that State being highly appreciated. The colder regions of Mexico produce corn, wheat, barley, and other cereals, and the maguey or agave, from which the national drink, *pulque*, is extracted. This plant is a native of Mexico, but it is found growing in the United States, although not in any great abundance. The maguey grows on the great plains, the plateaux, at an elevation of more than 7,000 feet above the sea. It is said that as far back as 1519 the native Mexicans cultivated the maguey, of which they made many uses. A great variety of products are obtained from the roots, leaves, and juice. Paper is made from the pulp of the leaves, twine and thread from their fibre, and needles from the sharp tips of their leaves. These leaves also serve as thatching for the houses of the poor. The rare and valuable Mexican manuscripts in ancient times were made of pulp from the maguey, which resembled the papyrus. Pulque is the fermented juice of the maguey. It has been

stated that in the city of Mexico over 250,000 pints of pulque are daily consumed, and in 1888 there were 822 shops in that city devoted exclusively to its sale. Mexico is becoming a wheat-growing country, and great impetus has recently been given to growing this grain. Wheat grows on the plateaux of Mexico from 6,000 to 9,000 feet above sea level. The area best adapted for its cultivation comprises some 52,000 square miles, and is situated in the States of Mechoacan, Jalisco Guanaguato, Aguascalientes, San Luis Potosi, and Queretaro. The Mexican plan of cultivation makes it possible to take off the land three crops every two years —one crop of wheat, and two crops of Indian corn. Fibre plants grow in great profusion over nearly every portion of the territory of the Republic. Principal among them are the agave, already mentioned, the banana tree, ramie, henequen, several kinds of cacti, among which figures the organ cactus, and a species of cactus growing abundantly in the territory of Lower California, which is called *cirio*, and from which a good quality of paper is manufactured. The mulberry tree is found in many localities, and experiments lately made in the States of Vera Cruz, Puebla, Daxaca, and Michoacan in the way of cultivating the silkworm, has produced good results. As regards the methods of cultivation in vogue in Mexico, they differ but little from those employed by the ancient Egyptians. Wooden beam ploughs with a small iron shoe are used. These make a furrow five inches broad by five deep. A hoe is also used, which often weighs from three to five pounds. With the exception of a few districts, all threshing of grain in Mexico is done by driving horses or mules around in a ring upon the straw, which is on the ground. The winnowing is done by men tossing the grain and chaff into the air with shovels.

NIJNI-NOVGOROD FAIR.

The following account of the Nijni-Novgorod fair, from the last report of the Belgian Consul-General at Moscow, is quoted from the *Board of Trade Journal*:—

Before the year 1816 the fair was held at Makarieff, in proximity to the monastery of Makaire. The site for this market was badly chosen, for in spring the waters of the Volga flooded the buildings, and during the summer months the shifting sands made the transport of merchandise difficult. In consequence of the fire which destroyed the warehouses of the Makariew fair in 1816, it was decided to transfer this market to Nijni-Novgorod. A French engineer, M. de Bethencourt, was entrusted by the Government with the construction of the buildings. On a rectangular space of ground, one side of which was bounded by the Oka and the three others circumscribed by a horse-shoe canal connecting itself with the Metcherskoë lake, were erected a large number of stone buildings one storey high. To the east and west of the fair place, there have been dug galleries serving as drains, connected on one side with the Oka and terminating in the other at the semi-circular canal. These buildings cost 12,500,000 roubles. Afterwards these erections were recognised as being insufficient, and new places were erected on the other side of the canal in the direction of the Volga.

The area of the lands, buildings, &c., reserved for the fair is about 722 deciatines (deciatine = 2·7 acres).

Situated on the left bank of the Oka, this place forms a vast triangle formed by the confluence of the two rivers. It is limited on the north by the Volga and the territory of the village of Sormovo; on the south by the Oka and the Makariew quarter of the town of Nijni-Novgorod; on the east by the Oka, and on the west by the villages of Sormovo and Gardeefka. In the centre of the fair there are buildings constructed by Bethencourt, which include 60 main houses, 48 of which are placed in lines parallel with the canal, four on the Cathedral place and eight adjacent to the Palace (*Glavni Dome*).

In the course of the last two years there have heen constructed along the canal 40 large stone buildings for warehouses. On the territory of the fair there were computed to be in 1890 more than 3,000 warehouses.

On the east, at the confluence of the two rivers, there is a stretch of stone, along which two quays have been established up the Oka, the St. Petersburg quay, and up to the Volga, the Siberia quay. This place is occupied by counting-houses and the warehouses of the steam navigation companies. Near the Metcherskoë lake are the tea warehouses. The Siberia quay is connected to the Moscow-Nijni railway by a branch worked by horse traction.

Above the bridge of boats, on the Oka, which connects the fair with the town of Nijni-Novgorod is a stretch of sand separated from the bank by an extent of water from 80 to 100 metres wide. On this sandbank, which communicates with the quay by means of temporary wooden bridges, are discharged the Oural iron and the Astrakhan fish cargoes.

The Nijni-Novgorod fair, the official opening of which takes place each year on the 15th (27th) July, only enters on its period of great activity in the first fortnight of the month of August. The success of the transactions depends, to a great extent, on the yield and sale of cereals. This fair is, in reality, only a temporary market organised by the Moscow manufacturers and merchants, who dispose of their products at the busiest period of the shipping season. The articles traded in are of Russian origin, and, in smaller quantities, those of Asia and Western Europe. Among the goods in which the largest amount of business is transacted may be cited, in the first place, cotton tissues, then metals, particularly iron from the Oural works, wool and woollen tissues, &c. Camels' hair, leathers and hides, hair, feathers bristles, furs, and wool are the principal articles bought by agents on account of foreign houses.

Indigos, drugs, and pharmaceutical products, wines, and liqueurs, colonial wares, sewing machines, instruments and tools, tissues of every kind, &c., are the chief foreign articles imported to the fair by the European frontier.

The active trade in cotton tissues exercises an influence on the well-being of the working population of the governments of Moscow and Vladimir; for, by reason of the aridity of the soil, the inhabitants of the villages are not generally engaged in agricultural pursuits, but are more particularly engaged in spinning and weaving. The provinces devoted to sheep-rearing are interested in the success of the wool and woollen tissues trade. The activity of the metallurgic works of the Oural is intimately connected with the output on the Nijni-Novgorod market of iron production at remunerative prices. The population of the government of Astrakhan, which lives chiefly by the produce of the fisheries, await with interest the results of the transactions of the fish trade.

The Nijni-Novgorod fair is therefore of great importance not only to the governments of the Volga, but also to many other provinces of the Empire. This market also plays a very considerable part in the Eastern or Asiatic trade as regards the import of the products of Siberia and Asia (China, Central Asia, and Persia), as well as the exchange of these products with Russian merchandise. However, since fairs have been opened at Irbit, Tumene, and Semipalatinsk, the supplies of certain Siberian products have diminished. The Trans-Caspian railway having facilitated the development of trade with Central Asia, a very large quantity of merchandise no longer comes to the fair, and is sent directly from Moscow to the places of consumption.

The value of consignments to the Nijni-Novgorod fair in 1890 was 181,256,831 roubles.

THE INCREASED CONSUMPTION OF MEXICAN TOBACCO.

It is only since the date of the Cuban War, in 1868, that what may be termed the tobacco era for Mexico, commenced. According to the French Minister in Mexico, it is to the system of manufacture introduced by Cuban emigrants that Mexico owes the progress which has been made in this branch of national industry. The success of Mexican tobacco is now assured in Europe, and it appears to fill the gap caused by the diminished product of Cuba. Good tobacco cannot be grown everywhere in Mexico, but on the coasts and in the warm and temperate regions it may be produced in abundant quantities, and of an excellent qualtity. Such lands are rare in the world; in the first place, Europe and the United States, situated in ultra-tropical regions, can only produce ordinary leaves, suitable for very cheap cigars. Spanish America produces a slightly superior article, but up to the present the exports from South America have been insignificant, and those from Java and Sumatra consist of leaves without any aroma, and of bitter taste. The only serious competition is with Cuba, but this will, it is said, not continue very long, as that region known as Vuelta-Abajo, which produces leaves of superior quality, and which enjoys a considerable reputation, is of small extent, and the land is exhausted by half-a-century's uninterrupted cultivation. The Mexican brands of San Andrès, Tuxtla, Acayucan, and Huimanguillo, which for fifty years have only been appreciated in the country itself, are now quoted everywhere. Other and newer brands are now also celebrated. It is now no longer the practice for Mexican tobacco before going to Europe to pass through Cuba to give it a fictitious name and value. At the present day the greater part of the Mexican cigars are sold under their own name, but a considerable quantity is still put up under Havana brands. There appears to be still something wanting to the Mexican cigars. Their aroma evaporates more quickly than that of their Cuban rivals, when the box is open, one reason being that the fermentation of the leaves is incompletely carried out. Occasionally, also, a slight earthy taste is found in the inferior qualities, which would disappear if the growers would adopt the system practised in Cuba, and subject the leaves to the same treatment. However that may be, Mexican cigars are now found in considerable quantities on the markets of Antwerp, Hamburg, and London, and it is stated to be a subject of regret on these markets that the cultivation o tobacco in Mexico does not develop itself more rapidly, and that the shipments are so irregular. Up to the present it has been the want of capital that has stood in the way of this development. Magnificent lands may be purchased in the States of Vera Cruz, Oaxaca, Guerrero, Chiapas, and Tabasco, at very low prices, and on these virgin lands the cultivation of tobacco might be carried on with marked success, it is said. Manual labour is cheap, and expenses generally are much lower than in Cuba, where land is dear and taxation very heavy. At Santa Rosa (State of Vera Cruz) a hectare of land (hectare equals 2·47 acres) yields 2,000 kilogrammes of tobacco at five francs the kilogramme, a return of at least 10,000 francs (£400), and the maize that is sown after the tobacco harvest covers the expenses of cultivation. The cost of transport of a ton of tobacco from Santa Rosa to Vera Cruz is about £4, and notwithstanding the fact that the wages of the Indians employed in tobacco cultivation have recently risen, the profits yielded by this industry are enormous, the rapid fortunes realised by planters and manufacturers who have been engaged some years in this business being a proof of it. To equal the *regalias* of Havana much will have to be done, it is said, in Mexican cultivation, but the average quality of the tobaccos of Vera Cruz, Tabasco, Oaxaca, and Chiapas is already equal, and in some cases superior, to that of the Cuban article exported in bales, for the leaves of the finest quality of Cuban tobacco are bought by the Havana factories, and are used for

making cigars of the best brands. Mexico could produce more tobacco than Cuba, if capitalists in the former country only realised the extreme importance of this branch of agricultural industry.

THE WOOL TRADE IN FRANCE.

A recent report by the French Chamber of Commerce at Constantinople states that the wool production of the world amounted in 1890 to 882,576,000 kilogrammes (kilogramme = 2·204 lbs.), of which 62,652,000 kilogrammes were produced by England, 204,300,000 kilogrammes by the European continent, 146,188,000 kilogrammes by North America, and 469,436,000 kilogrammes by Australia, the Cape, and La Plata. The world's wool production was greater in 1889 than in 1890, the amount for the former year being over 926,000,000 kilogrammes. In thirty years, from 1860 to 1890, the Australian production rose from 27,000,000 to 232,000,000 kilogrammes; that of the Cape from 8,000,000 to 41,000,000; and of La Plata and Uruguay from 15,000,000 to 123,000,000. France, in 1890, consumed about 64,000,000 kilogrammes of Australian wool, representing 425,000 bales—that is to say, more than a quarter of the total production of Australia and New Zealand. The United Kingdom alone consumes a larger quantity of these wools. In 1890 the total production of La Plata and Uruguay was estimated at 130,000,000 kilogrammes, not including the wool and skins of slaughtered sheep. Of this wool France takes 64 per cent., represented by a quantity of 205,000 bales. France therefore imported in 1890 168,000,000 kilogrammes of wool in the grease or washed, of which 64,000,000 was Australian and 82,000,000 kilogrammes La Plata wool. The remainder, 82,000,000 kilogrammes, represents wool of European origin and common wool from Africa and Asia Minor. These 168,000,000 kilogrammes, with an approximate value of £14,000,000 sterling, do not, however, represent the whole quantity consumed in the country, as no account has been taken of the French clip and the wool of imported sheep. Taking all these into consideration, it may be stated that France consumed in 1890 for her industries over 240,000,000 kilogrammes of wool—more than a quarter of the entire wool production of the world.

FRENCH TRUFFLES.

The *Board of Trade Journal* gives the following particulars respecting the production of truffles, which is extracted from a report of the United States Consul at Bordeaux;—

There are three species of truffles found in France—the black and most common, the white (highly prized), and the *truffe à l'ail,* which has a flavour of garlic. They are found in all soils, but chiefly in oak forests, or where the earth is damp and calcareous, thriving best in an almost sterile soil. The best that the country affords come from Périgueux and about Angoulême.

In appearance the ordinary truffle is about the size of a walnut, with a rough, brown, warty surface, closely akin to the potato, which it likewise resembles in consistency, though not in colour. Not yielding to cultivation, they must be sought for in chance places, nor is the method of obtaining them the less interesting.

Recently it has been found that dogs could be trained to perform the duties that are instinctive to the pig, and so great is the demand in France for the truffle that many of the canine species are now, in certain districts, possessed of this estimable talent. Finely cut or sliced truffles are mixed daily with their food, until at length they develop a liking for the flavour. Afterwards their owners conceal, in some portion of a field where truffles are supposed to exist, a little tin dish of *filet aux truffes*, covering the same with a few handfuls of earth. The dog is then brought out and urged to hunt for the dish, goaded by an empty stomach. When he at length finds it, he is caressed by his master, and thus, in the space of a few weeks he will readily learn to hunt for the vegetable itself.

Truffles are seldom found twice in the same place. A field that may yield a great quantity this year will be quite fruitless the next. Though Alexander Bornholz, a German scientist, claims to have transplanted and raised the article in question, repeated experiments to that end have proved but failures. The Count de Noá, a Frenchman, and a certain M. Rousseau, made like claims, but they have in each case been discredited.

The very fact that the truffle is a rarity, and that it grows only in certain districts, has been enough to make it an object sought after clandestinely by peasants or those who carry them to market. There are poachers for truffles as well as for game, who hunt by night with their dog or pig, a plague to landowners and a *bête noire* to local gendarmes.

Scarcely is there a canning establishment at this moment in France that does not, among other alimentary products, preserve this dainty. It has become as indispensable to the dinner table of the *noblesse* as the aromatic sprig of garlic to the frugal repast of the peasant.

The annual production is valued at about 3,000,000 dollars. The article is sold in the departments where found at 1 dollar per pound and at almost double that price at the principal markets of the larger cities. Not alone does the truffle thrive in France; they are found in quantities in Italy, Spain, and Holland, but are of indifferent quality compared with the French, lacking the delicate and incomparable flavour of the native product.

In the United States, especially in California, some attention has been given, within the past few years, to the gathering and preserving of truffles, and a number of Western packers have come to Bordeaux in

order to inform themselves regarding the canning process. It is a very simple one, the truffles being partially boiled, as tomatoes, asparagus, and other vegetables, and then jarred and sealed in their own diluted juice. All meat and game products are also "truffled," the vegetable being cut into small squares, and inserted into the substance of the article preserved.

In 1889 the imports of truffles into France were 22,585 lbs., and the exports therefrom 452,361 lbs. Of the latter quantity, 204,633 lbs. went to England, 107,276 lbs. to Germany, 38,990 lbs. to Belgium, and 24,387 lbs. to the United States.

MANUFACTURING INDUSTRIES OF SPAIN.

Consul Turner, of Cadiz, says that, although Spain does not figure among the leading manufacturing nations of the world, it cannot be denied that during the last few years great advancement in the development of this branch of industry has been made. Already her manufactures of chemical and pharmaceutical products are very important, and also those of paints, varnishes, and prepared cloth for artists, made at Madrid, Leon, and Barcelona. Among others, are the soaps of Seville, Cordova, Toledo, Madrid, Valladolid, and Saragossa; the candles of Madrid; the fertilizers of Huelva, Alicante, Haro, Barcelona, and Madrid; the matches of Tarragona, Aragon, Saragossa, Vittoria, Guipuzcoa, Madrid, and Leon; the syrups and essences of Seville, Granada, Barcelona, and Madrid; the syrups, acids, chlorides, sulphates, &c., of Madrid, Barcelona, Alicante, and Leon. There is a national manufactury of small arms at Toledo, of firearms at Oviedo, and of cannon in Seville and Trubia. Among the private industries, those worthy of notice are the establishments for the manufacture of arms at Toledo, cutlery at Albacete and Saragossa, and firearms at Eibar, Plasencia, and Oviedo. In Madrid, Barcelona, and Valencia surgical and astronomical instruments are manufactured. Musical instruments are made in Barcelona, Madrid, Valencia, Seville, Valladolid, Saragossa, and other cities. The clarionets of Salamanca, the flutes of Huesca, Teruel, and Valencia, and the banjos and guitars of Cadiz are famous. In Madrid and Barcelona very good pianos and organs are made. There are, in Spain, many paper factories, the best being those of Barcelona and Tolosa; of ordinary paper at Caravaca; of pasteboard at Gerona, Burgos, and Loix; of cigarette paper at Alcoy, Cocentayna, Onteniente, Bocairent, Bilbao, Valladolid, Segovio and Catalonia; of wall paper at Madrid and Barcelona. The principal centres for making furniture are Madrid, Barcelona, Cadiz, Vittoria, and Pontevedra. In the ceramic industry, Seville, Gijon, and Barcelona are distinguished for the production of fine opaque china, porcelain, tiles, &c. There are important manufactures of crystals and glasswares in Segovia, Malaga, Corunna, Carthagena, Barcelona, Bilbao, Oviedo, Guadalagara, and Saragossa; of gold, silver, nickel, and white metal goods in Madrid, Barcelona, Cordova, Saragossa, and Salamanca; and the finish of the steel goods of Madrid, Toledo, and Eibar is without rival. Most of the hemp of Spain is exported, but some of it is used in the manufacture of matting, among which that of Crevillente is well known. The canvas made of this hemp is used in the manufacture of shoes, and is an industry of some importance in Southern Spain. The manufacture of cotton goods, which is almost confined to Catalonia, is constantly growing. The principal factories are located in Barcelona, Mataro, Esparraguera, Sans, Granollers de Valls and Villanueva y la Geltru. There are others of less importance out of Catalonia, such as those of Valladolid, Saragossa, Cavada, Malaga and Guipuzcoa. The manufacture of knitted goods is confined to Barcelona, Mataro, Esparrayuera, and Reus. The manufacture of woollen goods has six principal centres—Catalonia, Alcoy, Bejar, Ezcaray, Antequera, and Palencia. In Caceres, Toledo, and a few other cities, there are also factories of some importance. The principal silk factories are in Valencia and its province, and in Murcia, Seville, and Almagro. Cork factories are found in the provinces of Caceres, Badajoz, and Gerona. Hats are made in all parts of Spain. Boots of all kinds are manufactured extensively in Barcelona, Saragossa, and Madrid; gloves in Seville, Cadiz, Saragossa, Barcelona, Madrid, Zamora, and Burgos; fans in Valencia, Barcelona, and Madrid; and leather goods generally in Madrid, Malaga, and Salamanca. There are extensive dry docks for shipbuilding at Bilbao and Cadiz. Both are private enterprises, but they have been well patronised by the Spanish Government. There are in Spain several other very important yards, some of which are under Government control. Consul Turner says that, judging by the amount paid to the Government for the right to engage in manufacturing enterprises, the most important provinces in Spain are Madrid, Barcelona, Valencia, Seville, Saragossa, Malaga, Cadiz, Gerona, Granada, and Alicante. It should be borne in mind that nearly all of the industries mentioned above are small and primitive, and in only a few are modern methods followed, or modern machinery used.

INSECT PLAGUES IN EGYPT.

In a recent report by the British Vice-Consul at Alexandria, it is stated that the plague of locusts which has been devastating Morocco has been extending itself to Egypt. Some little time ago, clouds of locusts made their appearance and settled, for the most part, on the banks of the Nile or on the edge of the desert, forming large yellow patches,

easily discernible at a distance. They at once began to breed, and, although immediate steps were taken to destroy them, large numbers of the eggs have already been hatched. An examination of about thirty deposits of eggs is said to have shown that the usual number laid by each female is from ninety-seven to a hundred. The Government at once issued the strictest orders to the mudirs to use every possible means to destroy the locusts, and competent officials were sent round the country to organise and direct the work of extermination. Millions of locusts and eggs have been destroyed, but there are still large numbers in the country. When eggs are discovered, either the field is ploughed up or flooded, or the eggs are collected and destroyed. The old locusts are easily destroyed while breeding, but the young crickets, in the earliest stage, when they are hopping about in every direction, give more trouble. The usual method followed in this case is to enclose the spot in which the crickets are found by a number of men drawn up in the form of a crescent. A ditch is then dug from one horn of the crescent to the other, and the men close in, driving the young locusts, by means of palm branches, into the ditch, where they are destroyed and buried. When the young locusts are further developed, they cease to hop, and march in densely packed armies. It is at this stage that they are said to be most destructive, but they are more easily exterminated, as they move slowly, and can be surrounded with fuel and burned. From the energetic measures taken by the Government, it is hoped that this pest may be stamped out before any serious harm has been occasioned, but as many eggs are still known to be deposited in the country, it is impossible to foretell the extent of the calamity, and it is possible that many eggs are being hatched in the desert. Up to the present time it is reported that little damage has been done to the cotton crops, but it is difficult to obtain any reliable information on the subject. The system employed in Cyprus for the destruction of locusts has been adopted in Egypt when practicable. Another insect plague, in the shape of a repulsive-looking scale insect, made its appearance in Alexandria some time ago, and last year committed great ravages in the gardens adjacent to the town, attacking trees, shrubs, and the fruit of the date palm. Various measures have been tried, but the only efficacious one appear to be that of cutting the branches and carefully brushing the boughs. Unfortnnately, however, no general regulation has yet been put into force, and consequently the efforts of some individuals are nullified by the apathy of others, and the plague still continues and threatens to spread throughout the country. The insect has been classified as *Crossotoma Ægyptiacum*, and was probably imported from America. It is popularly known as *cotonina*, from its resemblance to cotton. A decree has now been issued, prohibiting the transport of trees and shrubs from Alexandria to other parts of the country.

THE AGRICULTURAL PRODUCTS OF MALAGA.

Consul Newson, of Malaga, says, in his last report, that the superficial area of the province of Malaga measures 1,837,197 acres, of which about a third is devoted to the cultivation of wheat, barley, maize, corn, *garbanzos* (chick peas, an important article of home consumption and of exportation), beans, and rye. An extent of 282,180 acres is under grapes, and 104,007 acres under olive trees. Other large areas, embracing many acres, are given up to the cultivators of the orange, lemon, *chirimaya* (a species of apple), fig, plum (ten varieties), cherry, (five varieties), mulberry, pomegranate, banana, apple, peach, pear, walnut, chestnut, lime, *prisco* (a species of peach), and apricot. Of late years, the almond tree has received considerable attention, as there is a great demand for the nut, principally in the United States and England. The grape vine lands of the province, once the source of so much prosperity, have, for several years past, greatly deteriorated in value, hundreds of acres having been devastated by the phylloxera. The vineyard districts of the province are now reduced to two prominent varieties of grapes—the Pedro Ximen and muscatel—although many other varieties are grown in small quantities. Other classes have totally disappeared, chiefly owing to the ravages of the mildew and phylloxera. During the years 1888–90, the loss was very great, to such an extent that the exportation of raisins from the consular district of Malaga alone fell from 641,835 boxes in 1866 to 70,456 boxes for the fiscal year ended June 30, 1891, being a decrease of 571,379 boxes in four years. At Denia, about 320 miles from Malaga, on the Mediterranean, the grape is extensively cultivated, and is rapidly coming into competition with the Malaga market. While the article is not so good as the muscatel, yet the rapid process of curing permits their export at a much lower price, and much earlier than from Malaga. In the former district the grape is dipped into hot lye, and it is a raisin in a few days, while in Malaga it takes a fortnight to cure the muscatel. The process of converting grapes into raisins is very simple. When the grapes are thoroughly ripe, they are picked in bunches, with their stems, and laid upon boards with wooden frames, slanting at an elevation of 45° towards the west, or on sandy ground, sloping so that the afternoon sun can be utilised. Coarse cloth is used to cover them at night, in order to keep off any dew. The grapes are turned over from time to time, until, at the end of two or three weeks, they become raisins, some appearing on the stems just as the branches come from the original stock, while others are picked from the stems, and packed singly by hand into boxes. The muscatel grape, while making the largest raisin, is very delicate, and will not bear transhipment. The vines are usually planted eight feet apart, and are never trailed, but are permitted to grow as bushes, not reaching,

ordinarily, over four feet in height. They are cultivated by keeping the grass out from between the rows and the soil loose. The bunches are sometimes turned towards the sun while growing on the vine, to ripen the fruit which hangs in clusters near the ground. The Denia grapes are dipped in hot lye, as already stated, and hence are cured much more quickly than other grapes, but present a less attractive appearance than the Malaga variety. The lemon, though an important article of export, is not so valuable as the lemon of Italy, Portugal, or Brazil, or even Mexico, and the quantities shipped have considerably fallen off, chiefly owing to competition from abroad, and to the ravages of the disease among the trees, known as the *serpeta*, or *pulgon* (blight), which consists of a gummy substance which oozes from the trees and exhausts their vitality. Orange trees are sometimes afflicted with the same disease as that which attacks the lemon, and yet they appear not so much affected by it. The almond trees grow almost anywhere without cultivation. They are to be found growing on the almost perpendicular sides of mountains, on the tops of mountains, in the valleys, in fields, and apparently out of the rocks. The olive is one of the oldest trees in the province, some of the trees in the district of Malaga having reached the age of from three hundred to five hundred years. They are generally small, and most of them have only part of the trunk of the tree left, while new branches shoot out from the deformed body and bear the fruit. The fig tree is a prolific bearer, and produces two kinds of fruit in the season—one following the other—from the same tree, and the figs are said to be excellent. The tree has a large fine leaf, and is considered healthy and hardy.

THE SWISS CHEESE INDUSTRY.

Cheese-making is the most important agricultural occupation in Switzerland, as upon it depend the prosperity of the milk industry, the rearing of milch cows, and the value of pasture-land. The country is not adapted to the fattening of cattle in sufficient numbers to supply the wants of the population, and the Swiss consumer is to a great extent dependent on foreign countries for meat. There is a brisk business in sending young cattle to fatten on the other side of the frontier, and in re-importing them. According to a recent British report from Berne, during the past year 326,506 animals of all kinds, of a total value of £2,440,239, were imported into Switzerland, while 71,930, value £649,440, were exported. Austria-Hungary, France, and Italy supplied the greater number of the cattle imported for slaughter, while those imported from Germany were rather for farming purposes. The total export of cheese last year amounted to £1,528,288, and of condensed milk to 529,797. The price of cheese rose during the year, owing to a deficient supply caused by the difficulty of obtaining milch cows in sufficient numbers. Swiss milch cows are in great demand in Germany, and the fact of their exportation to that country, coupled with the increased quantity of milk required by the condensed milk factories, hampers the development of the cheese industry. The best market for Swiss cheeses is France, where the hard Emmenthal cheeses are much sought after, the total value exported to that country in 1890 amounting to £426,564. Germany and Austria import the soft and juicy Emmenthal cheeses, while those imported by Italy are, for the most part, of an inferior quality. The question of the duties levied by foreign countries on Swiss cheese is one which naturally occupies an important place in the negotiations for the renewal of the Swiss commercial treaties. The following are the duties at present in force:—France, 3s. 4d. per 100 kilos. (the octroi duties varying from 8s. to 12s.); Italy, 6s. 8d.; Germany, £1; United States, £1 12s.; Austria-Hungary, 8s. 4d. The prospect of an increase in these duties, such as that contemplated by the new French tariff, is regarded with much apprehension, as it will be felt by the whole milk industry.—*The Times.*

CORK TRADE IN SPAIN.

The following notes on the condition of the cork trade in Spain are quoted in the *Board of Trade Journal* from the monthly *Bulletin* of the French Chamber of Commerce in Barcelona:—

In examining the strips of Catalonian cork, irregularities are observed which render certain of the elementary operations of the industry difficult. This is the more unfortunate because the cork trade is relatively prosperous, and constitutes the sole occupation of a great number of the inhabitants of the north-east of the province of Gerona. It is precisely to these irregularities, which occur in a much less degree in the cork of Andalusia, Estramadura, and Portugal, that the Catalonian cork workers owe their reputation as skilful artisans. This reputation is well deserved, if we consider the difficulties which they have to overcome to obtain a good return from the cork of their country.

An approximate estimate, and no other can be obtained, gives an annual consumption of 400,000 quintals of cork in Catalonia. Of these, 200,000 are produced in the province itself, 150,000 are brought from other parts of Spain, and 50,000 from abroad. The value of the total amount is estimated at twelve million pesetas, and the expenses of the manufacture of corks, package, and transport, amount to eight million pesetas more. The eight millions of expenses are thus divided:—

Breaking off and scraping the strips, 400,000 pesetas; squaring the cork, 2,000,000; manufacture of corks, 3,500,000; selecting and packing, 1,400,000; and transport of the strips to the factories and of the

bales of corks to the ports of shipment, 700,000. Total cost, 8,000,000 pesetas.

If we analyse the previous operations we find—

1. That 400,000 quintals of cork produce 1,400,000 corks of all sizes, that is to say, 3,500 corks per quintal.

2. That 1,400,000 corks have produced a sum of 20,000,000 pesetas, that is to say, 1,428 pesetas a thousand, expenses and profits included.

If we analyse the expenses of manufacture, taking the quintal as the base of our calculation, we discover the following figures:—

Boiling and scraping the strips, 1·00 pesetas; squaring, 5·00; manufacture of the corks, 8·75; selection and packing, 3·50; and transport, 1·75. Total of the cost per quintal, 20·00 pesetas.

The province of Gerona exports annually an average of 46,670 bales. This represents approximately, as we have said above, 1,400,000 corks. Of these bales, 14,283 pass through the Custom-house of Palamos, 16,723 by that of San Feliu de Guixols, 12,669 by that of Portbou, and 2,999 by that of Barcelona. There are manufactured, in our region, thirty-two different kinds of corks, classified according to their length and diameter, from the homeopathic cork of 22 mils. for 5 or 10, to the *bretas* of 64, for 45 or 55 mils., and their price differs from 1 to 50 pesetas a thousand. These prices obtained at the factory, which vary to an infinite degree according to the purity and the quality of the cork out of which they have been made, can only be considered as general, and susceptible of modification according to locality and circumstance.

There are 8,228 individuals employed in the different factories; these are divided into nine categories, namely, *taponeros*, or corkmakers proper; *cuadradores*, whose business is to square the cork; *raspadores*, who remove the first bark from the strip; *escogedores*, who choose the corks; *blanquedores*, or bleachers; *calibradores*, who arrange the corks in accordance with their size; weavers; spinners; and carders. The men whose business it is to boil the cork, to square it, to choose it and to classify it, usually earn a fixed salary of 3 pesetas a whole day. Those who make the corks, working for so much a thousand, earn from 18 to 20 pesetas a week, and sometimes 25. But there are others who, unfortunately, make from 5 to 6 pesetas a day. The men engaged in transporting the goods earn 2·50 pesetas for the whole day.

Corks enter free of duty into England and Norway. Since the passing of the MacKinley Tariff, the exportation of Spanish corks to the United States has absolutely ceased. The *trefinos* corks for champagne, and the small corks of the same best quality, having been well paid for, the proprietors of oak-cork are now selling their strips at a price at least 3 pesetas higher than during 1889 and 1890. It is therefore to be hoped that the cork industry will continue to prove prosperous in spite of foreign competition, of the MacKinley Tariff, and of the altered conditions of the Republics of South America, which last have closed a market which was already considerable, and which seemed likely to increase in importance.

Notes on Books.

A HAND-BOOK OF INDUSTRIAL ORGANIC CHEMISTRY. Adapted for the use of Manufacturers, Chemists, and all interested in the utilisation of Organic Materials in the Industrial Arts. By Samuel P. Sadtler, Ph.D. Philadelphia: J. B. Lippincott Company.

The author says that his endeavour has been to bring within the compass of a single volume an account of the more important chemical industries, or groups of related industries, written in language that may be understood by those not specially trained in chemistry. He further states that, "in taking up the several industries for survey, it has been thought desirable, first, to enumerate and describe the raw materials which serve as the basis of the industrial treatment; second, the processes of manufacture are given in outline and explained; third, the products, both intermediate and final, are characterised, and their composition illustrated, in many cases, by tables of analyses; fourth, the most important analytical tests and methods are given, which seem to be of value either in the control of the processes of manufacture or in determining the purity of the products; and the fifth, the bibliography and statistics of each industry are given, so that an idea of the present development and relative importance of the industry may be had." The various industries are dealt with in the following order:—(1) Petroleum and mineral oil industry; (2) industry of the fats and fatty oils; (3) essential oils and resins; (4) cane-sugar; (5) industries of starch and its alteration products; (6) fermentation industries; (7) wine, spirits, bread making, vinegar, and milk industries; (8) vegetable textile fibres, paper making, gun cotton, collodion, celluloid, &c.; (9) textile fibres of animal origin; (10) animal tissues and their products, leather industry, glue and gelatine manufacture; (11) industries based upon destructive distillation; (12) artificial colouring matters; (13) natural dye colours; (14) bleaching, dyeing, and textile printing.

A HAND-BOOK OF BRITISH COMMERCE: being a Descriptive and Statistical Account of the various Articles forming the Import and Export Trade of the United Kingdom. By P. L. Simmonds. London: Moffat and Paige.

This little work contains an account of the various articles of commerce, arranged in alphabetical order from *abaca* to *zinc*, and in each entry is given particulars as to source of supply, and amount of imports and exports. There is at the end of the book

an alphabetical table of the general imports of the United Kingdom in 1890, with the quantity and value of the principal articles received.

THOMAS SOPWITH, M.A., C.E., F.R.S.: with excerpts from his diary of fifty-seven years. By Benjamin Ward Richardson, M.D., LL.D., F.R.S. Longmans, Green and Co.

Mr. Sopwith, the eminent civil engineer, who died in 1879, left behind him a very extensive diary; from this Dr. Richardson, who was an old friend of Mr. Sopwith, has compiled an interesting memoir, in which the particulars of a long and active life are related, and particulars are given of many distinguished men with whom the subject of the memoir came in contact. The many radical changes that have occurred in the manners of the people, and the modes of locomotion during the greater portion of the present century, are also alluded to in these pagef. Mr. Sopwith was a member of the Society of Arts, from 1843 until the date of his death.

General Notes.

ALGERIAN WINE. — During the year 1890, 57,289,733 gallons of wine were produced in Algeria from an area of 263,000 acres. The estimated value of the wine is £2,300,000, and more than half of that produced is sent to France.

SCHEVENINGEN SPORTING EXHIBITION. — An International Sporting and Fishing Exhibition, including horses, is to be held at Scheveningen, near the Hague, in the summer of 1892, under the patronage of the Queen of the Netherlands. Baron A. N. F. M. van Brienen du Groote Lindt, of Wassendar, is Commissary-General of the committee appointed to organise the Exhibition.

CHICAGO EXHIBITION.—The moving sidewalk at the World's Fair grounds was opened to the public on November 25th. About 300 representive men went by special train from Chicago to inspect this novelty. One of the criticisms made of this means of transportation was with reference to the danger to old men, ladies, and children, but experience from a week's use of the road shows that there is no trouble in this respect. The speed is so slow that there is no difficulty in getting on or off. This exhibit is on a wooden trestle 25 ft. high, the sharpest curve having a radius of 75 ft. The sidewalk is 900 ft. long, having 360 deg. of curvature in that length. When hauling about 350 passengers, which is about one-third of the capacity of this experimental line, the additional power expended is about 2½-horse power over and above that necessary to move the walk. The *Railroad Gazette* says:—The Road is now in full operation, and is carrying a large number of passengers. A full view of the World's Fair grounds is obtained from the seats of the cars.—*The Engineer.*

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock:—

JANUARY 20.—Prof. VIVIAN B. LEWES, "Spontaneous Ignition of Coal, and its Prevention." Sir FREDERICK BRAMWELL, D.C.L., F.R.S., will preside.

JANUARY 27.—F. W. EDRIDGE-GREEN, M.D., "The Scientific Value of Lovibond's Tintometer."

FEBRUARY 3.—T. PRIDGIN TEALE, "Dust, and How to Shut it Out."

FEBRUARY 10.—E. PRICE EDWARDS, "Burning Oils for Lighthouses and Lightships." Sir LYON PLAYFAIR, K.C.B., F.R.S., will preside.

Papers, the dates of reading of which are not yet fixed:—

"Iceland." By TEMPEST ANDERSON, M.D.

"Ancient and Modern Art Pottery of Japan." By ERNEST HART.

"The Fisheries Department: its Position and Prospects." By J. W. WILLIS BUND.

"The Congo State." By Captain V. LOVETT CAMERON, R.N., C.B.

FOREIGN AND COLONIAL SECTION.

Tuesdays, at Half-past Four or Eight o'clock; due notice of the hour will be given:—

JANUARY 12.—ERNEST SATOW, C.M.G., "The Laos States of Upper Siam." Sir THOMAS WADE, G.C.M.G., K.C.B., will preside. 4.30 p.m.

FEBRUARY 16.—LEWIS ATKINSON, "The Kimberley Exhibition."

MARCH 15.—F. A. PEZET (Peruvian Consul General), "Peru."

Papers, the dates of reading of which are not yet fixed:—

"Australasia." By Sir EDWARD BRADDON, K.C.M.G.

"Newfoundland." By Sir WILLIAM WHITEWAY, K.C.M.G.

INDIAN SECTION.

Tuesday afternoons, at 4.30 p.m.:—

JANUARY 21.—HERBERT JONES, "From Tien-Shan to the Pamirs—experiences on the Russo-Chinese Frontier." The paper will be illustrated by lantern slides.

FEBRUARY 11.—LORD LAMINGTON, "Recent Travels in Indo-China." Lieut.-General Sir ANDREW CLARKE, G.C.M.G., C.B., C.I.E., will preside.

MARCH 3.—Surgeon-General Sir WILLIAM JAMES MOORE, K.C.I.E., "Indian Sanitation and the International Congress of Hygiene." Major-General Sir OWEN TUDOR BURNE, K.C.S.I., C.I.E., will preside.

MARCH 24.—G. H. M. BATTEN, formerly of the Bengal Civil Service, "The Opium Question." Sir JOHN STRACHEY, G.C.S.I., C.I.E., will preside.

APRIL 7.—Dr. J. AUGUSTUS VOELCKER, "The Agricultural Needs of India."

APRIL 28.—Sir WILLIAM WEDDERBURN, Bart., "Reorganisation of Agricultural Credit in India." The Right Hon. Sir JAMES CAIRD, K.C.B., will preside.

MAY 19.—JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock:—

JANUARY 26.—WILLIAM MORRIS, M.A., "The Woodcuts of Gothic Books." Sir GEORGE BIRDWOOD, K.C.I.F., C.S.I., LL.D., M.D., will preside. The paper will be illustrated by lantern slides.

FEBRUARY 23.—J. WILLIAM TONKS, "Artistic Treatment of Jewellery: Jewel and Address Caskets."

MARCH 8.—

MARCH 29.—E. ROSCOE MULLINS, "The Decorative Uses of Sculpture." ALFRED GILBERT, A.R.A., will preside.

APRIL 12.—C. PURDON CLARKE, C.I.E., "English Brocades and Figured Silks."

MAY 17.—GEORGE T. ROBINSON, "Decorative Plaster Work" (II.). J. HUNGERFORD POLLEN will preside.

CANTOR LECTURES.

The following courses of Cantor lectures will be delivered on Monday evenings, at Eight o'clock:—

PROF. GEORGE FORBES, F.R.S., "Developments of Electrical Distribution." Four Lectures.
January 25, February 1, 8, 15.

PROF. WILLIAM ROBINSON, M.E., Assoc-M.Inst.C.E., "The Uses of Petroleum in Prime Movers." Four Lectures.
February 29, March 7, 14, 21.

BENNETT H. BROUGH, "Mine Surveying." Three Lectures.
March 28, April, 4, 11.

DR. PERCY FRANKLAND, F.C.S., "Recent Contributions to the Chemistry and Bateriolology of the Fermentation Industries." Four Lectures.
May 2, 9, 16, 23.

HOWARD LECTURES.

A Special Course of Six Lectures, under the Howard Bequest, will be delivered on the following Friday evenings, at Eight o'clock, by PROF. W. CAWTHORNE UNWIN, F.R.S., "The Development and Transmission of Power from Central Stations."

February 5, 12, 19, 26, March 4, 11.

JUVENILE LECTURES.

Two lectures, suitable for a juvenile audience, will be delivered by PROFESSOR JOHN M. THOMSON, Sec. C.S., on the "Three States of Matter: Solid, Liquid, and Gaseous," on Wednesday evenings, January 6 and 13, 1892, at 7 p.m.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 4...Chemical Industry (London Section), Burlington-house, W., 8 p.m. Mr. Boverton Redwood, "The Gallician Petroleum Industry."
Surveyors, 12, Great George-street, S.W., 8 p.m. Discussion on Mr. C. H. Bedell's paper, "Party and Party-fence Walls."
Medical, 11, Chandos-street, W., 8½ p.m.
Victoria Institute, 1A, Adelphi-terrace, W.C., 8 p.m. Dr. Hill, "From Reflex Action to Responsibility."
London Institution, Finsbury-circus, E.C., 5 p.m. Mr. G. Du Maurier, "Social Pictorial Satire."

TUESDAY, JAN. 5....Royal Institution, Albemarle-street, W. 3 p m. Prof. J. McKendrick, "Life in Motion, or the Animal Machine."
Pathological, 20, Hanover-square, W., 8½ p.m.
Zoological, 3, Hanover-square, W, 8½ p.m. 1. Dr. J. Anderson, "A small Collection of Mammals, Reptiles, and Batrachians from Algeria." 2. Mr. F. E. Beddard, "The Earthworms collected by Dr. J. Anderson in Algeria." 3. Mr. R. I. Pocock, "Some Myriododa and Arachnida collected by Dr. Anderson in Algeria and Tunis." 4. Mr. Oldfield Thomas, "The Species of the Hyracoidea."

WEDNESDAY, JAN. 6...SOCIETY OF ARTS, John-street, Adelphi, W.C., 7 p.m. Juvenile Lecture. Prof. J. M. Thomson, "The Three States of Matter—Solid, Liquid, and Gaseous." (Lecture I.)
Geological, Burlington-house, 8 p.m.
Photographic Club, Anderton's Hotel, Fleet-street, E.C., 8 p.m. Mr. T. Charters White, "Photo Micrography."
Archælogical Association, 32, Sackville-street, W., 8 p.m.
Civil and Mechanical Engineers, 7, Westminster Palace Hotel, S.W., 7 p.m. 1. General Meeting. 2. Mr. R. Bolton, "The Square Drilling Machine and its Uses."

THURSDAY, JAN. 7...London Institution, Finsbury-circus, E.C., 7 p.m. Prof. Ernest Pauer, "Judgment of Musical Works."
Royal Institution, Albemarle-street, W., 3 p.m. Prof. J. G. McKendrick, "Life in Motion, or the Animal Machine."

FRIDAY, JAN. 8 ... Astronomical, Burlington-house, W., 8 p.m.
Geologists' Association, University College, W.C., 8 p.m. Mr. Horace W. Monckton, "The Geology of the Country round Stirling."
Clinical, 20, Hanover-square, W., 8½ p.m.

SATURDAY, JAN. 9 ... Botanic, Inner Circle, Regent's-park, 3¾ p.m.
Royal Institution, Albemarle-street, W., 3 p.m. Prof. J. G. McKendrick, "Life in Motion, or the Animal Machine."

Journal of the Society of Arts.

No. 2,042. Vol. XL.

FRIDAY, JANUARY 8, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

JUVENILE LECTURES.

Professor J. M. THOMSON gave the first of his course of Juvenile Lectures on Wednesday evening, 6th inst., the subject being "Three States of Matter: Solid, Liquid, and Gaseous." Professor Thomson said that in the first lecture the general common properties which may be observed in the three states of matter would be considered. A short general description of the different states of matter was then given, the three conditions and the change from one to another being experimentally illustrated. The lecturer then pointed out that no strict line of demarcation could be found between the three conditions, and showed the intermediate viscous condition as illustrated by flowing pitch and plastic substances.

After showing the effect of temperature and pressure in producing the changes in the conditions of matter, the special properties of solid bodies were described, these being illustrated by experiments dealing with the elasticity of different substances, their fusibility and infusibility, and the various capacities of certain substances for conducting heat and electricity. Reference was next made to the changes which certain substances show in occupying an allotropic condition, and, in certain cases, undergoing change in colour without changing their composition. Some of the special properties of liquids were then described, including the different expansions by heat—the question of the different pressures exerted by their vapours. The production of cold by the rarefaction of air was beautifully illustrated by Mr. Fleuss, with his new pump. In this experiment water was frozen by a few strokes of the pump.

Professor Thomson then spoke of the passage from gaseous to liquid conditions, and showed how cold was produced by the evaporation of liquefied gases, using, as an illustration, liquefied carbonic acid gas. Reference was then made to the diffusion of liquids, and to the power which certain substances possess of passing through membranes in the process of dialysis. Passing to the special properties of gases, the lecturer illustrated his remarks by experiments showing the diffusion of gases into each other, and the different rates of diffusion belonging to different gases.

Professor THOMSON will deliver the second lecture of the course on Wednesday next, the 13th inst., at seven o'clock. This lecture will be devoted to a consideration of the different changes that may be observed in the action of various material substances on each other when in different states.

FOREIGN AND COLONIAL SECTION.

The first meeting of the Section for the present Session will be held on Tuesday afternoon, 12th inst., at 4.30 p.m., when a paper on "The Laos States, Upper Siam," will be read by Mr. ERNEST SATOW, C.M.G.

Chicago Exhibition, 1893.

FINE ARTS COMMITTEE.

The first meeting of this Committee was held on Monday, 4th inst. Present:—Sir Frederick Leighton, Pres. R.A. (Chairman of the Committee), Philip H. Calderon, R.A., Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., C.I.E., F. Seymour Haden, F.R.C S., Sir James D. Linton, President of the Royal Institute of Painters in Water Colours, Walter William Ouless, R.A., Edward J. Poynter, R.A., Lumb Stocks, R.A., Marcus Stone, R.A., W. Hamo Thornycroft, R.A., H. Stacy Marks, R.A., and Sir Henry Trueman Wood, Secretary of the Royal Commission.

TRANSPORTATION COMMITTEE.

The first meeting of this Committee was held on Wednesday, 6th inst. Present:—B. Francis Cobb, in the chair, Sir Nathaniel Barnaby, K.C.B., C. V. Boys, F.R.S., Henry Chapman, James Dredge, Francis Elgar, LL.D., Walter H. Harris, Charles Holmes, George N. Hooper, with Sir Henry Trueman Wood, Secretary of the Royal Commission.

Proceedings of the Society.

CANTOR LECTURES.

PIGMENTS AND VEHICLES OF THE OLD MASTERS.

By A. P. Laurie, M.A.
King's College, Cambridge.

Lecture II.—Delivered December 7th, 1891.

PART I.

Palette of Cennino Cennini.

In the first lecture we have dealt with the preparation of panels for painting, with gilding, and with the use of tinfoil and coloured varnishes. The recipes are similar to those at present in use, and if equally good and durable results are not obtained, it seems to be due more to want of care and of taking time than to serious defects of method. We come next to the consideration of the pigments used during the best period of art, with the view of carefully examining their nature and properties. Here we are met by several difficulties.

In the first place, we are embarrassed by the number and variety of pigments mentioned. I cannot attempt to deal with more than a few of them in a short lecture, and must select those of apparently the most importance. In the next place, it is in many cases difficult to identify an old pigment, or to recognise the same pigment under different names. Much ingenuity, however, has been expended on this subject, and, on the whole, with tolerably satisfactory results.

In the third place, a large proportion of the old pigments are fugitive, and we are consequently somewhat embarrassed by this fact, as it throws upon us the burden of picking out those of real value from among the many described.

It is of importance, in this connection, to remember the various uses to which the pigments were put. Roughly, these may be described as, painting in fresco, painting in secco on walls, painting in secco on panels, painting in oil, and illuminating MSS.

Now, of these, the most destructive to pigments is fresco painting, and consequently few pigments could with safety be used, while, on the other hand, many pigments might safely be used for illuminating that could not be used for anything else. Protected from damp and from the action of light, preserved between closed leaves of vellum, and probably never touched by sunlight, many fugitive pigments might be safely used.

It is, furthermore, impossible to consider this subject of the durability of pigments by itself, apart from the mediums used to paint with. When we come to consider the question of vehicles, we shall find that certain pigments may safely be used with some vehicles that cannot be used with others. There is another very pertinent question that can be asked, How many of the old works of art have perished completely from natural decay? Are not those we possess the successful experiments among many failures? It is a common remark to say of an Old Master that it is as fresh as the day it was painted. There are very few that really have this appearance. If carefully examined, the colours have, in many cases, dulled and faded. The pigments still look bright owing to their contrast one with another, though often, when examined separately, they appear quite dull.

Unfortunately, too, there are pigments which, while quite legitimate under old conditions, are no longer suitable for use in the polluted air of modern cities. It is also of importance to consider climatic conditions in this connection. For instance, it is an easy problem to paint permanent pictures in the dry climate of Egypt, a very difficult one to do the same in England. All these matters have to be taken into consideration, giving us a very complex problem to be dealt with.

Let us begin by considering the list of pigments mentioned by Cennino Cennini. This list we can add to afterwards, but it forms an important and useful introduction. They are as follows:—

Red.—Sinopia (red ochre), cinabrese (red ochre and white), cinnabar, minium, amatisto (hæmatite), dragon's blood, lake.

Yellow.—Ochre, giallorino (Naples yellow), orpiment, risalgallo (realgar), zafferano (saffron), arzica.

Green.—Verde terra, verde azzurro (copper green, malachite), verderame (verdigris).

White.—(Chalk) bianco sangiovanni, (white lead) biacca.

Blue.—Azzurro della magna (azurite), azzurro oltre marino (ultramarine).

Black.—A soft black stone. Black made of the tendrils of young shoots of the vine. Black made of the skins of almonds, or the kernels of peaches. Lamp black.

Let us take these pigments in order, and consider them one by one.

Sinopia.—This is one of the many names under which red ochres are mentioned, whether native or prepared by roasting yellow ochres. They have been used from the earliest times, and are perfectly reliable for all kinds of work. There is no need to dwell longer on them.

Cinabrese.—This pigment is described by Cennino as being a mixture of red ochre with chalk. This is very commonly done now in order to prepare a bright red, and is a perfectly harmless practice.

Cinnabar (vermilion).—This pigment is known in two forms, native and artificial. Cinnabar, or sulphide of mercury, is one of the commonest ores of that metal, and is occasionally found in pieces of a fine red colour when ground. Probably it was first used in this form. A much finer pigment is, however, obtained by subliming sulphur and mercury in a covered crucible, when the cinnabar is found at the top in crystalline masses. This method of preparation must have been known from very early times.

The preparation of mercury is described by Theophrastus, 300 B.C., and the early alchemists, such as Geber, were familiar with many of the compounds of mercury, so that there can be little doubt that they were also familiar with the artificial preparation of vermilion.

The oldest of the MSS. on the preparation of pigments, that of Theophilus, supposed to be of the 12th century, describes the preparation of artificial vermilion; and similar recipes occur repeatedly in MSS. of later dates. Returning again to Cennino, there can be no doubt that the vermilion he refers to is artificial. He says:—"This colour is produced by alchemy, performed in an alembic. . . You may find many recipes, especially among the friars. . . Always purchase whole cinnabar. . . That which is convex on the top, and covered with needle-shaped filaments, is the best." It has been suggested more than once that the old masters used the native cinnabar, but, on the whole, the evidence is, I think, against this view. Evidently Cennino, at any rate, was familiar with the artificial variety.

No people have been more famous than the Chinese for the preparation of vermilion, and they still have a deservedly high reputation for it. It seems to have been used by them, from very early times, as a royal colour; and we find, according to Marco Polo, that the paper currency of Kublai Khan was stamped with the royal signature in vermilion. This remains the custom to the present day in China. The Chinese prepare the vermilion now by subliming sulphur and mercury, and then grinding, washing, and floating over. According to an account published recently in the *Chemical News*, the vermilion is suspended in water containing a little size. In this it settles slowly, and the top layer is then removed. I have examined many samples of vermilion from China. It is a little difficult to get the genuine article, as most of that sent in here is merely European vermilion repacked in Chinese paper. The real article is unmistakable. It is not quite so bright as English vermilion, but is of a finer and softer colour, and is much more finely ground, being as soft as silk between the fingers. On subliming it, an ash is left, weighing from ·1 to ·05 per cent., or even less, of the whole. The ash is brown, and is apparently a trace of oxide of iron.

Unfortunately, English vermilion makers have departed from the ways of their forefathers. They prepare a product by heating the black sulphide of mercury with strong caustic potash, and the product is seldom free from alkali and alkaline sulphides.

Chinese vermilion may be safely mixed with white lead. I know a sample so mixed which has remained unchanged for 40 years. I should not like to try the same experiment with many of the vermilions made here.

You will ask, is vermilion a permanent colour when properly prepared? This question is somewhat difficult to answer, but I will give you my view of the matter.

In the first place, let us consider the facts before us. Vermilion is a sulphide of mercury. Now this sulphide can exist in two varieties, the red or vermilion and a black sulphide. We can pass from the black to the red sulphide. We can also, unfortunately, pass very easily from the red to the black sulphide. If Chinese vermilion (that is practically the same article as Cennino describes) is ground in oil, painted out, and exposed to sunlight in a south window, it *turns black in a few months*. This agrees with Cennino's statement:—"But remember that vermilion is not durable when exposed to the air; it is more lasting on pictures than on walls, because, by long exposure to the air, it becomes black when applied to walls."

Evidently, then, Cennino distrusted this pigment, though I venture to differ with his reason for doing so. We know of too many pigments that are affected by air or moisture. The case of vermilion seems to be different from these. No chemical change is needed. The action

of the sun's rays alone seems to re-arrange the molecules into the black variety. In the experiments on water-colours made by Captain Abney and Professor Russell, it was proved that, while many so-called fugitive colours were permanent in dry hydrogen, this did not save vermilion from turning black.

Now, let us look at the evidence on the other side. I have already mentioned the experiment with vermilion in Mr. Holman Hunt's studio. But we can get other examples. There are many reds in the National Gallery that can only be produced by vermilion. Among others, look at the red in the "Rape of Helen," Benozzo Gozzoli, 1420—1498 (591).

How, then, are these apparently contradictory facts to be reconciled? If we accept the theory put forward by Abney and Russell, that the rate of destruction of a pigment is a function of the amount of light falling on it, and that, consequently, a feeble light for 100 years produces the same effect as a strong light for one year, we cannot reconcile these facts. But this opinion of theirs has not been accepted by the best authorities, such as Prof. Church; nor does it agree with the experience of chemists in other directions. Let us take, as an example, the action of heat in assisting chemical change. There are some changes which take place at a gradually accelerating rate, as the temperature is raised, but there are others which do not begin until a certain temperature is passed. My own opinion is, that vermilion is a case of this kind; that it does not change in the diffused light of a room, but is quickly altered by direct sunlight. In this way only can I account for the facts before us. Under proper conditions, then, vermilion, properly made, is, I believe, a reliable pigment, and may be safely used. European vermilions, unless carefully washed with weak acid, and then with water, are not reliable. In this way 70 per cent. of the ash is removed.

Minium or Red Lead.—This pigment, prepared by the careful roasting of litharge, has been long known. It is described by Pliny, and, according to this authority, was discovered 320 B.C. There can be no doubt that this pigment has been much used in the past, and it is still very largely used for house-painters' work. It is, however, very rarely used by artists, as it has fallen completely into discredit. To my mind there is no more beautiful red, and I think it is a great loss to the palette. Two reasons for not using it are usually given. One, that it tends, like all lead pigments, to blacken in impure air. The other that it is actually decomposed by daylight, returning to the dull brownish-yellow litharge. It is of interest here to note what Cennino Cennini says of it:—"This pigment is only proper to be used in pictures; for if it be used on walls, on exposure to the air, it suddenly becomes black, and loses its colour." It used to be customary to wash it before use with wine and water. One curious recipe for preserving minium is given by De Mayerne, a physician in the Court of Charles I., to whom I shall have to refer more than once in my next lecture. He advises washing it repeatedly with vinegar. More than one reference shows that it was not considered a very safe pigment. It was prepared by roasting white lead. It is now, I believe, usually prepared from litharge. No doubt the minium prepared from white lead would be a finer pigment. I have not made any experiments with it myself, but I propose doing so, as I doubt if it is rightly condemned, and its beauty makes it well worth reintroducing to the notice of artists.

Amatisto.—There seems to be considerable doubt as to the nature of the pigment so called by Cennino Cennini. He says it is a natural colour, and is produced from a hard firm stone from which burnishing tools can be made. It is a purple colour, and is probably a variety of hæmatite. (Mrs. Merrifield seems to think it may have been native cinnabar.) One curious point is that Cennino says it is the colour that cardinals use. "The cardinals had the red hat by a decree of the Council of Lyons, held in 1245 by Innocent IV. They did not adopt the red dress till 1464, that is under the pontificate of Paul II; therefore at the period when Cennino was living they still wore the purple colour" (Tambroni).

Dragon's Blood.—I have already referred to this resin in the first lecture. It is mentioned by Pliny, and is the resin obtained from the calamus palm. (*Pterocarpus Draco.* Linnæus.) Dragon tree. Cennino says of this pigment, "Let it alone; it will never do you much credit."

Lake, which comes next in order, I shall treat of at the end.

Yellow ochre.—Nothing need be said about this pigment. A natural earth, it has been used from the earliest times, and is absolutely permanent. Cennino describes a very fine variety he found near Casole.

Giallorino.—The history and nature of this pigment is somewhat obscure. Cennino distinctly states that it is a volcanic product. He

states that it is not a brilliant yellow though brighter than ochre, and never makes bright greens. Mrs. Merrifield considers that several pigments were included under this name. I cannot do better than quote her summing up of this matter.

1. "A native mineral yellow pigment, known by the name of *giallolino*, *giallolino di Napoli*, *jaune de Naples*, *luteolum Napolitanum*."

This is doubtless the yellow referred to by Cennino. All trace of it seems to be lost, though probably a proper search in a volcanic district would lead to its discovery.

2. "An artificial pigment which was composed of the yellow protoxide of lead, and which was called *giallolino*, *giallolino fino*, *giallolino di fornace di fiandra*, *luteolum Belgicum genuli* (the last is a Spanish term), and *massicot*, of which there were two varieties, namely, the golden or yellow, and the white or pale *massicot*."

This pigment can be prepared by gently roasting white lead. It is now known as Turner's yellow. It is apt to turn black, like all lead pigments, the fault of our towns, not of themselves.

"3. An artificial pigment made at Venice, composed of *giallolino fino* and a certain kind of *giallo di vetro*, or vitreous yellow, for which a recipe is given in the Bolognese MS. in the Venetian dialect, and which appears to have been the Hornaza of the Spaniards."

This recipe is worth quoting, and is as follows :—

"To make yellow glass for paternosters or beads: —Take of lead 1 lb., of tin 2 lb.; melt and calcine them, and make glass for paternosters.

"To make *giallolino* for painting :—Take 2 lb. of this calcined lead and tin, that is, 2 lb. of this glass for paternosters, 2½ lb. of minium, and ½ lb. of sand pounded very fine; put it into a furnace and let it fine itself, and the colour will be perfect."*

This pigment must have been a yellow lead frit. Probably effective on fresco walls, but of little or no use in oil. Mrs. Merrifield then goes on :—

"I consider it established that they used two kinds of Naples yellow, namely,—

"1. A native mineral pigment found in the neighbourhood of volcanoes, the nature of which is not accurately known, and which was called 'giallolino di Napoli,' and 'jaune de Naples,' and which is synonymous with the first kind of giallolino above mentioned.

"2. An artificial pigment now in use (?) composed of the oxides of lead and antimony, called 'giallo di Napoli,' 'jaune de Naples,' and Naples yellow, and which was not known to the old Italian artists."

Apparently the manufacture of the more modern artificial Naples yellow has now ceased. I failed to find either that it was made or that anyone had ever heard of its being made in Naples. The manufacture has long ceased apparently. The colour now sold as Naples yellow is, I understand, usually a mixture of yellows. One sample I examined was massicot pure and simple. A fine yellow can be made from lead and antimony, and I have some here which I have made myself. Possibly a search on Mount Vesuvius might result in the rediscovery of the original Naples yellow.

Orpiment or Auripigmentum.—This sulphide of arsenic exists both as a natural and artificial pigment. The natural sulphide is found in volcanic districts. It has not been found in any of the ancient Greek or Roman paintings. Cennino says it is unfit for use in distemper, because it turns black. Cennino mentions it as being an artificial pigment. It was known and used through the best periods of art, but always with special precautions, as being liable to change and to attack other pigments.

Cornelius Jansen says, "Orpiment will ly fayre on any colour except verdegris, but no colour can ly fayre on him; he kills them all."

De Mayerne, speaking of Vandyck, says :— "He makes use of orpiment, which is the finest yellow that is to be found, but it dries very slowly, and, when mixed with other colours, it destroys them. In order to make it dry, a little ground glass should be mixed with it. In making use of it, it should be applied by itself, the drapery (for which alone it is fit) having been prepared with other yellows. Upon them, when dry, the lights should be painted with orpiment; your work will then be in the highest degree beautiful."

This addition of powdered glass is advised by Cennino for another reason. It will be noted, from these accounts, that it does not seem liable to alter in itself, but to act on other colours. If it was liable to change, it would be advisable to use some different medium than oil. There can be no objection apparently to using it in the way stated, but it would not be safe to put it into the hands of a modern artist, as he would probably mix it too freely with other colours. The reason for not painting it over with verdigris will be given when we come to that pigment.

* MS. of the 15th century in the library of the R. R. Canonica Regolari, in the Convent of the St. Salvatore in Bologna.

Risalgallo Realgar, or Red Orpiment.—This pigment, prepared by heating gently orpiment, has similar properties, and must be used with the same precautions.

Zafferano (Saffron).—Cennino recommends preparing this colour by putting the saffron in a bag and rubbing it down with lye. He says it is good for staining linen or paper, and it makes a beautiful green with verdigris, but must not be exposed to the air. This is of course a very fugitive colour, and was probably only used for temporary purposes. Saffron has already been mentioned as suitable for colouring varnishes.

Arzica.—Cennino says that this pigment is not durable when exposed to the air, and is not to be used on walls. According to the Bolognese MS., it is a lake prepared from weld (wild mignonette). It is probably the most permanent of the yellow lakes. When used for dyeing, weld yields a very beautiful yellow, which stands exposure to sunlight remarkably well, and is probably the most permanent yellow dye. It is used by William Morris for his tapestry work. At the same time the yellows in the old tapestries do not seem to bear exposure and time so well as the reds and blues. In many cases they are almost completely gone. So that Cennino's judgment of this pigment is probably correct.

This completes the list of yellow pigments mentioned by Cennino Cennini. He has, however, omitted one of the first importance from the list, to which he devotes a great part of his book, namely, gold. He describes elsewhere the grinding up of gold leaf for use in miniature painting, and as his panels are laid on with gold, he depends on it for many of his effects. The use of gold as a yellow pigment, however, apart from decorative work, is not common, as far as my experience goes. It is, however, used by Holbein, the process being apparently to lay on the gold, and then glaze with dull yellow up to the high lights, just allowing the gold to show through at the high lights. Another remarkable instance is the famous rainbow portrait of Queen Elizabeth. The inner lining of the robe is a rich yellow. The high lights are given by means of gold.

Those who have not tried do not know what a wonderfully rich effect can be produced by the glazing over gold of transparent pigments.

Verde Terra (Terra Verte).—There is no need to say anything about this natural earth. Like the ochres, it is useful and absolutely reliable, and always has and always will be used. Cennino says that it may be used instead of bole for preparing the surface for the gold.

Verde Azzurro.—Cennino says that this green is prepared from Azzurro della Magna. He also states that it must not be ground too fine, as it loses its colour. According to Mrs. Merrifield, however, Verde Azzurro is a native copper carbonate, similar to green bice. Cennino's description certainly suggests a frit of some kind, as the frits are spoilt by too fine grinding. It is not impossible that the azzurro della magna (blue copper ore) was converted into a green pigment artificially. There can be no doubt, however, that green copper ores were known and used as pigments. I shall, however, discuss this point at greater length when I come to the copper blues.

Verderame (Verdigris).—Of this pigment Cennino says it is good in pictures tempered with glue, but must be never mixed with white lead. He also says it is improved in colour by grinding with vinegar, but is not durable.

This pigment was largely used apparently both by the Italian and Flemish painters. It was prepared by exposing plates of copper to the action of acetic acid vapour, and it is a sub-acetate of copper. A finer preparation was made by dissolving it in vinegar, and letting it crystallise out. This preparation was known as *verde eterno.* It is a very transparent blue green, and was used to glaze over other colours. A drapery, for instance, painted in yellow and glazed with verdigris, would be of a fine green. I have tried to illustrate this hue, but not altogether successfully. It is possible, however, that the verdigris is somewhat at fault. The green is, however, a fine one, especially as no yellow brighter then ochre is used in the solid painting. Verdigris is perhaps the most interesting of all the pigments used by the old masters, as we know it to turn black and to invade and destroy other colours. Its successful use by them, therefore, is little short of marvellous. I will treat of this, however, at some length when the mediums used by the old masters come under discussion, and it will be our most interesting example of what can be done by the right selection of a medium.

Bianco Sangiovanni (Whitening).—This is merely whitening, or chalk, and is recommended for fresco work by Cennino Cennini. His method of preparation is, however, a beautiful one, He takes slacked lime, and mixing it with water, keeps it for eight days, changing the water every day. He then makes it into small cakes, and lets them dry in the sun. As he says, the older they are (that is,

the more complete they change back into carbonate) the whiter they become.

Biacca (White Lead).—Cennino says that it must not be used for fresco, as it turns black, but may be used on pictures. This pigment was apparently known to the ancients, though not used on walls. It always has been, and still is prepared (some of it) in the same way, by the action of vinegar vapour on metallic lead; a process popularly known as the Dutch process. There is no reason to suppose that the pigment made now by this process differs in any way from that used by the old masters. It is absolutely essential for oil painting. It may be as well to explain here, and now, certain points about this pigment which seem to be not clearly understood by artists.

In the first place it is necessary to understand that stack lead, as I shall call it, that is white lead made by the action of acetic acid vapour on lead plates, contains two substances, one known as carbonate the other hydrate of lead, and it owes its peculiar properties to the intimate union in the right proportion of these two. One of the most important of these properties is its power of combining with the oil, to form what is known as a lead soap, thus forming a leathery substance of great durability. All the so-called permanent whites do not do this, and, consequently, remain merely a mixture of particles of pigment with the oil. Furthermore, a great deal of white lead is made now by a precipitation process. It is whiter than stack lead, and therefore preferred by artists; but it does not combine with the oil, as stack lead does, and is not so reliable. A mixture of the two is also sold, which is fairly satisfactory, I think.

Now, to illustrate what I mean by this combining with the oil, I will describe an experiment made by a manufacturer of whites. He coated some pieces of canvas with different whites, such as patent white, precipitated white lead, and so on, and fixed them up on a roof, where they would flap about in the wind, and get all the weather going. The stack lead canvas was not affected by this treatment, but the other whites cracked and dusted off. I am now repeating this experiment, as I think it a very important one. Whatever may be the result, there can be no doubt that stack lead was used by the old masters.

To go on to another point—the darkening of white lead. In impure air, containing certain compounds of sulphur, white lead turns to an unpleasant brown. If, however, it is then exposed to sunlight, it quickly recovers again and returns to its original white.

Besides this action, if kept in the dark it becomes of a yellow colour, not disagreeable. This is quite different from the effect of sulphuretted hydrogen, but can also be removed by exposure to sunlight.

The ease with which white lead is thus restored has not, I think, been allowed for sufficiently in considering its instability as a pigment.

Azzurro della Magna.—Cennino says of this blue that it may be used in fresco. According to Mrs. Merrifield, it is a blue copper ore. Cennino says that it is found in the veins of silver mines, and that it comes from Germany and from Greece. There was, probably, no blue more universally used than this during the best periods of Italian Art. It is repeatedly referred to, and Professor Branchi, of Pisa, has found it in many old pictures and frescoes. I do not doubt that blue often seen on the walls of our cathedrals, where a little of the old colouring remains, is this copper ore. It is true that the original preparation of copper blues seems to have come in also very early, and it is difficult, therefore, to say which may have been used in any particular case. I will not trouble you with all the information collected on this point. With reference to the use of copper blues in painting, however, a few remarks are necessary. In the first place, it seems to have been the practice to lay on this blue with size and not with oil, the opinion being that in oil it turned green. Whether this is so or not is deserving of an experiment. In order to be able to use size in an oil painting, the oil surface was rubbed with a little garlic. In this way a sticky surface was formed on which the size can grip. The use of size in this way is undoubted, and has been found in restoring some ancient pictures. Doubtless, also, the blue would be laid on with *certain* varnishes, but this point must be left in the meantime. After laying on with size it was varnished over in many cases.

In fresco, of course, these difficulties would not present themselves. Copper blue and green have fallen into great discredit in modern times, and I propose to consider here shortly how far this is justifiable.

In the first place, their use in oil seems to have been always objected to, certain varnishes or size being used. But if used with size or in fresco there seems to be no reason to doubt their durability in pure air. Copper tends,

under certain conditions, to oxidise and carbonate into blues and greens, as is seen on old bronze. This is the final product from exposure to damp and air, and doubtless a stable one. The fact of similar colours being found in copper ores, confirms the view that copper blues and green, at any rate of native origin, should be stable compounds.

Can they then be recommended for use now in fresco painting. I fear not, and because of our old enemy, sulphur. In the pure air of a country church, where gas has never been heard of, I would not fear to use them, but they are, I consider, more susceptible even than white lead, and for this reason. White lead is easily restored, at least in oil, by exposure to sunlight. Copper, I believe, will be found not to recover in the same way. It will gradually blacken without recovery. Consequently the re-introduction of copper ores for fresco work cannot, I fear, be recommended.

There was another very interesting copper pigment known from the earliest times, which is not mentioned by Cennino Cennini, and which was known as smalt. The modern smalt is a cobalt blue, which is wanting in durability, though it would doubtless be easily prepared so as to be absolutely permanent. The old smalto, smalt, and the artists' cobalt blue, all belong to the same class of pigments, that is, they are rough glasses, or frits as they are called. The modern smalt is so composed that it decomposes very easily. Now two substances can be used to colour these frits, cobalt and copper. How far back the use of cobalt goes for this purpose does not matter at present. The use of copper from very early times is well known. These copper frits were largely used by the Egyptians, and they seem to have been famous for their preparation. Sir Humphry Davy analysed a lump of this copper frit from Pompeii, and found its composition to be —carbonate of soda 15, silica 20, copper 3.

Vitruvius says (vii. 11.) mix copper filings, alkali, and finely ground sand, make into balls with water, and fuse in a glass furnace.

An interesting paper in the *Comptes Rendus*, No. 108, was published a short time ago by F. Fouqué on this Egyptian blue. It is too long to quote here.

Professor Russell has made many experiments on it, and I have here some of his preparations. The interesting result of his work is, that he has produced a whole series of shades from purple to green. The knowledge of this preparation must be very old, as the streak of green colour on the fragment of coffin lid given me by Prof. Middleton was evidently a frit. It consisted of some transparent green fragments, and was unaffected by the reagents that would have at once changed a copper ore. As this lid was about 1500 B.C., the use of these frits is taken back to a very early period.

They are quite useless in oil, as fine grinding immediately destroys their beauty, but are, I believe, especially applicable to fresco work. I know of no blue at present in the market which can be safely recommended for fresco painting, and I think that these blues might well be revived for this purpose. The manufacture of a cobalt frit or common smalt might well be improved, so as to make a reliable pigment of it.

Azzuro Oltre Marino (*Ultramarine*).—We now come to the most famous of all blues, real ultramarine, prepared from lapis-lazuli. Cennini says, "Ultramarine is a colour more noble, beautiful, and perfect than any other colour; and its good qualities exceed anything we can say in its favour." The utmost pains used to be taken with its preparation from the stone, and it was always very expensive. Certain monasteries were famous for preparing it, and supplied it to the artists they employed; and many stories are told of their stingy ways with this colour, and how they suspected the artists of stealing it, and so on. It is still prepared, but has been replaced by the artificial ultramarines. These are similar in chemical composition, and very beautiful, and the best qualities seem durable. But it is very questionable if they equal in any way the real article. I quote in full Cennini's description of the method of preparing this colour. It is very similar to the recipes given in other MSS.

"CHAP. 62.—*Of the nature of azzurro oltre marino* [*ultramarine blue*], *and how it is prepared.*

"Ultramarine blue is a colour more noble, beautiful, and perfect than any other colour, and its good qualities exceed anything we can say in its favour. On account of its great excellence, I shall speak of it at length, and give you full directions for preparing it; and you must pay great attention to them, for they will bring you honour, and be of much service to you. And with this colour and gold (which are the great ornaments of our art) you may produce the finest effects. First take some lapis lazzari; and if you would know how to distinguish the best stones, take those which contain most of the blue colour, for there is mixed with it what is little better than ashes. That which contains least of these ashes is the best. But be careful that you do not mistake for it azzuro della magna, which is as beautiful

to the eye as enamel. Pound it in a covered bronze mortar, that the powder may not fly away; then put it on your slab of porphyry, and grind it without water; afterwards take a covered strainer, like that used by the apothecaries for sifting spices, and pound again as much as is required. But bear in mind that, although the ultramarine becomes finer the longer it is ground, yet the colour is neither so rich nor so deep; and that the fine sort is fit for miniature-painters, and for draperies inclining to white. When the powder is prepared, procure from the apothecary's six ounces of resin of the pine, three ounces of glue (*mastrice*), and three ounces of new wax to each pound of lapis lazzari. Put all these ingredients into a new pipkin, and melt them together. Then strain them through a piece of linen into a glazed basin, add to the mixture a pound of the powder of lapis lazzari, mix it all well together into a paste. And that you may be able to handle the paste, keep your hands always well anointed with linseed-oil. This paste must be kept at least three days and three nights, and must be stirred a little every day; and remember that you keep it for fifteen days or a month, or as long as you please. When you would extract the azure from the paste proceed thus. Prepare two sticks, with handles neither too thick nor too thin, about a foot long; let them be well rounded at the end and polished. Then, your paste being in the glazed basin into which you first put it, add to it a porringer full of lye, moderately warm; and with these two sticks, one in each hand, turn and squeeze, and mix the paste thoroughly, exactly in the manner that you would knead bread. When you see that the lye is perfectly blue, pour it out of the glazed basin; take the same quantity of fresh lye, add it to the paste, and stir with the sticks as before. When the lye is become very blue, pour it into another basin, and add more lye, as before. When this lye is very blue, pour it into another glazed basin; and continue to do so as long as the lye is tinged with colour. Then throw it away; it is good for nothing. Range all the basins before you on a table, in the order in which they were drawn off—that is to say, the first, second, third, and fourth—then, beginning at the first, with your hand stir up the azure, which, by its weight, will have sunk to the bottom; and then you will know the depth of the azure colour. Decide how many shades of the azure you will have, whether three, or four, or six, or what number you please, always remembering that the first-drawn extracts are the best, as the first porringer is better than the second. And if you have eighteen basins of extract, and you wish to make three shades of azure, take the contents of six basins and mix them together; that will be one shade. Proceed in the same manner with the others. But remember that if you have good lapis lazzari, the azure from the first two extracts is worth eight ducats the ounce. The last two extracts are worse than ashes. However, your eye must be accustomed not to spoil the good azure by mixing with the bad; and each day remove the lye, that the azure may dry. When it is quite dry, put it into skins, bladders or purses, as may be most convenient."

PART II.

On the Lakes used by the Old Masters.

The success in the production of permanent pictures by the great painters of Italy and Holland, encouraged me to inquire into the pigments used by them, with a view to assisting the modern artist in his selection of pigments and methods of painting.

As the subject is a very large one, I have begun by selecting the lakes for inquiry, and propose to state here the results of my investigations into the methods used to prepare such pigments, reserving an account of the methods of using them for the next lecture.

By lakes I mean pigments prepared by staining, or dyeing, a white powder or precipitate with vegetable or animal colouring matter. They have been used for painting from the very early times, but they are of very unequal permanency, and often fade or change in colour.

I found on beginning the inquiry that a considerable amount of material existed to form the basis of experimental work.

It seems to have been customary to collect and write down recipes for the preparation of colours and directions for using them, and consequently MSS. exist, some dating as far back as the 13th century, and some bearing the names of men known to be in communication with the best painters of the time, which contain a large amount of detailed information, which has been brought together by modern writers in a convenient form. Besides Eastlake's "Materials for the History of Oil Painting," we have an English translation of the manuscript of Cennino Cennini (15th century), by Mrs. Merrifield, and a translation of the manuscript of Theophilus (13th century), by R. Hendrie.

The most valuable of all is Mrs. Merrifield's "Ancient Practice of Painting." Mrs. Merrifield was sent out in 1845, by Sir Robert Peel, to inquire for and collect such manuscripts, and has edited and translated several in the work referred to above.

There are other works of older date than these, such as the "Arte Vetraria," by Neri (1612) and "L'Art de Teinture," by Hello (1701).

For information as to the colours used in

classical times, I am indebted to Prof. Middleton, who has collected into his article for the new edition of the "Dictionary of Antiquities," all that is known of the Egyptian, Greek, and Roman pigments, and has kindly allowed me the use of the proof sheets.

I have, however, confined the inquiry to a period dating roughly from the 13th to the 17th century, and have collected from manuscripts within that period seventy-four separate recipes for the preparation of lakes. Most of these, however, are merely repetitions one of another. The earliest method of preparing lakes seems to have been the staining of white earth, with the coloured juice of a flower. Prof. Middleton says that this was a method used in Rome, and some lake evidently prepared in this way was found at Pompeii. Accordingly we find in the oldest manuscripts with which we have to deal recipes of this kind.

For instance, a recipe for the preparation of lake in this way occurs in the manuscript of Eraclius, which is regarded as not being later than the 13th century:—

"Thus when painters wish to imitate sil atticum they put dried violets into a vase of water over the fire to boil, and when boiled down they are strained through a linen cloth, and rubbed down in a mortar with chalk, and so a colour like sil atticum is made."

Again we find Eraclius says:—

"Flores in varios qui vult mutare colores,
Causa scribendi quos libri pagina poscit,
Est opus ut segetes in summo mane pererret,
Et tunc diversos flores arteque recentes."

NOTE.—The above quotations are taken from Mrs. Merrifield's translation of the manuscripts of one "Jehan le Begue," notary to the masters of the mint in Paris, who compiled them (1431) from the manuscripts of one "Jehan Alcherius." They contain the recipes collected by Jehan Alcherius himself, and also the manuscripts of S. Audemar of Eraclius, and part of that of Theophilus. Mrs. Merrifield has corrected the version of Eraclius, and the manuscripts of Jehan le Begue by the copy of Eraclius bound up with Theophilus, and found by Raspe in Trinity College Library, Cambridge, now at the British Museum (Egerton Manuscripts, 184 A).

"Inveniet properetque sibi decerpere eosdem,
Cumque domum fuerit, caveat ne ponat in unum,
Illos, sed faciat quod talis res sibi poscit
Desuper equalem petram contriveris istos
Flores; incoctum pariter tum contere gypsum,
Sic tibi siccatos poteris servare colores.
Ex quibus in viridem si vis mutare colorem,
Calcem commisce cum floribus; inde videbis
Quod tibi mandavi, veluti prius ipse probavi."

It will be seen that when a purple colour is required, a neutral substance is used; when a green, lime is added. The colour in the former recipe is consequently green.

In order to use the colours thus prepared for illuminated manuscripts, they were mixed with a little gum arabic or white of egg beaten up, directions for this occurring frequently. I have prepared a green pigment by boiling the petals of violet with water, filtering and evaporating the filtrate slowly with a little French chalk and gum arabic.

The result shows that such pigments can be prepared with no great difficulty, and would doubtless give soft and pleasing tints.

Eraclius gives also another method of preparing lake by allowing ivy juice to slowly evaporate in a porous jar till thick enough to use as a colour.

DE EDERA ET LACCA.

"Propositis rebus edere satis utile robur.
* * * * * *
Vere novo, reduci cum gaudent omnia succo,
Arboribusque repert humor, ...
* * * * * *
Nam subula rami, loca per deserta forati,
Emittunt viscum, quem qui sibi sumpserit illum,
Transferet in rubeam coctum prurigine formam;
Sanguineumque sibi leviter capit ille colorem,
Hunc sibi pictor amat et scriptor diligit eque.
Hinc etiam roses fit parcia tincta colore.
Quæ quoque caprinas, quæ pelles tingit ovinas."

The preparation of a lake from ivy is also described by S. Audemar.* He advises the addition of madder straining through a cloth, and then evaporating over a fire. "And while it is on the fire, put it frequently with a twig upon your rod to try it. If it is thick enough, let it cool and harden, so that you may be able to make it into cakes."

In this recipe he says take lac, that is, the gum of ivy; and in other recipes the month of March is mentioned as the right time to collect the gum from the young twigs. This gum is referred to in Balfour's "Manual of Botany," and is stated to have certain medicinal properties, but it is not mentioned in the "Pharmacopœia," and the wholesale druggists know nothing of it. I have not been successful in preparing such a lake from the young twigs of English ivy—the expressed

* Supposed to be not later than the end of the 13th century. Contains some recipes from Clavicula. A 12th century MS.

juice merely drying up into a dark green—but I have obtained a yellow gum from the ivy in Italy, which, on exposure to air, darkens gradually to a ruby colour on the outside. Apparently, however, to get a fine colour from it, the Italian sun is necessary.

We soon find, however, that these methods are replaced by more scientific ones, derived from the art of dyeing, which, of course, reached great perfection in very early times. In the MS. of Jehan le Begue we find several recipes for the preparation of lakes in the modern method, which, as they were compiled by him from the MSS. of Alcherius, belong to the 14th century.*

We find in these recipes the substance from which the colouring matter is to be obtained is, first to be boiled in a ley, made from wood ashes or with a stale urine, and then the colour precipitated by the addition of alum. Traces of the older method, however, are to be found, as frequently the addition of gypsum as well as alum is mentioned. Some of these recipes indicate considerable knowledge of the properties of alum basic salts, and their tendency to form a precipitate under certain conditions. The following quotations from Mrs. Merrifield's translation of the manuscripts of Jehan le Begue will serve to illustrate the methods used in the 14th century:—

"*To make a rose colour.*—Take brixillium scraped very fine with a knife or with glass, and tie it in a fine piece of linen, not tight, but loose and easy. And put it, tied up in that manner, into a new glazed earthen jar, to soak in ley or in urine; and if the urine is stale, so much the better. If you cannot have any such, take very strong ley and put with the said piece of linen containing the brixillium, some of the white chalk of three or four times the weight of the brixillium, more or less, as by looking at it you may think fit, according to the goodness of the brixillium. Afterwards add some pulverized raw alum, in quantity about one-fourth of the chalk or thereabouts, more or less, and mix all the things together, always leaving the said brixillium tied up in the said piece of linen, and leave it so for about one hour. Next place the jar upon a fire, not of wood, but of charcoal, and let it boil, but not too fast for the space of a quarter of an hour or less, so as just to melt the alum. Then take the said bag of brixillium out of the vase, and press it and screw it out well, in order that the whole of the colour may run out of it in the said vase; and then remove the colour, hot as it is, from the fire, and put it on a hollow lump of chalk or upon a brick of baked clay, in order that the urine or ley may be immediately absorbed into the stone, and the colour itself remained thickened and half dry. Afterwards let it dry completely in the sun, and then remove the colour, which is of a rose colour, from the stone or brick with a knife, and put it by for use. When you wish to use it take as much as you require and powder it, that is, grind it upon a hard and smooth stone with gum water, which must be made of two-third parts of gum arabic dissolved in so small a quantity of water as barely to cover the colour when the water is added and strained through a linen cloth, and one-third part of clear water mixed with the said gum so dissolved and strained. And with the gum water, thus made, temper your rose colour to a proper consistence, and use for whatever you please."

* For instance, we find "Continentur hoc volumine de coloribus ad pingendum capitula scripta et notata a Johanne Archerio seu Alcherio, Anno Domine 1398, ut accepit a Jacobo Cona, flamingo pictore Commorante tunc Parisiis," and so on, from Jehan le Begue.

As a further example of the methods employed, the following recipe from a MS., not later than the middle of the 15th century, may be taken:—*

To make good and fine lake.—"Take 1 lb. of clippings of rosato, and put them into very strong ley made of ashes, such as the dyers use, in a new glazed jar, and set it on the fire to boil, and boil it slowly for the space of two paternosters, then pass the ley and the shavings through a clean linen strainer, and press it strongly with the hand so that all the ley may pass out; then put back the ley to boil again without the clippings, and when it is boiled, throw it on the shavings which are in the strainer, and press the strainer hard with the hand, so that all the ley may run out, and put it by. Throw away the shavings and wash the strainer well, so that there may not remain in it any of the hairs of the shavings. Next take 5 ozs. of roche alum in fine powder, and put it a little at a time into the ley, until the ley begins to settle, which you may know by its turning almost entirely to a thick scum, from top to bottom, and you must keep on mixing the ley with a clean spoon until it becomes cool, and settles; then put the ley into the clean strainer and strain it all off, and the lake will remain on the strainer. Let it remain on the strainer until quite dry, and then put it into a small basin of glazed earth full of clear and cold water, and stir and rub it up well with the hand until it diffuses itself; all the scum which rises to the top at first must be thrown away with a feather; then wash the strainer well and pour into it the water in which you have put the lake, and the clear water will pass out along with the alum, and this is called purifying it from the alum. And when the lake is nearly dry, remove it from the strainer, and spread it out with a broad knife on a new tile, let it dry in the shade, and before it has done drying, cut it into pieces according to your

* This manuscript was found by Mrs. Merrifield in the library of RR. Canonici Regolari Convent of S. Salvatore in Bologna.

fancy, and let it dry, and it is done. And know that the more it is purified from the alum, the more beautiful, and lively, and the better it is. And observe this secret, that if you wish to have the lake a brighter colour and one which will never change, when the shavings are boiling, add a lump of assafetida as large as a chestnut."

These two recipes give in some detail the general methods in use during the 15th, 16th, and 17th centuries for the preparation of lakes. There are, however, certain variations in detail that are worth noting. The introduction of assafetida is not again suggested, but in a receipt of later date the substance is boiled with fennel seed. This recipe is worth quoting in full, as it shows that they were aware that under certain conditions the colour would carry down alumina without the addition of an alkali.

"*To make a most beautiful purple lake.*—Take an ounce of fine grana or cochineal, a quarter of an ounce of roche alum, and about a bocale full of common water. Boil the water with a quarter of an ounce of fennel seed until it is diminished one-third; then add the grana or cochineal finely pulverized, and boil the whole over a slow fire for a quarter of an hour; then add the pulverized roche alum, and let it boil for another quarter of an hour. After this, take it from the fire, strain it through a linen cloth into a new and unglazed earthen porringer, and leave it there for eight days. You must then decant the water, or take it up gently with a sponge, evaporating the little which remains, until the colour is condensed, which you must afterwards keep in shells, adding to it a little lemon juice."*

I have tested this recipe, and find that a precipitate is thrown down of a purple colour. The addition of lemon juice referred to here, and in some other recipes, causes the lake to become more of a crimson and less of a purple.

Occasionally lime is to be added to the ley, prepared from wood ashes, thus making it into caustic potash; and in one recipe we are told that the urine must be kept 20 days, then boiled, skimmed, and filtered. Occasionally lime water alone is proposed instead of ley. Alum is usually called roche alum, but occasionally an alum zuccarino is mentioned. The addition of tartar is mentioned in a recipe in the Padua MS., and the addition of salisgeme, or pure rock salt, is once or twice referred to. Occasionally the addition of powdered travertine, egg shells, or fish bones is advised; and directions are frequently given for filtering the ley through the wood ashes several times with a view to obtaining a saturated solution. In a recipe given by Alcherius, a little ley is added to the alum before adding the alum solution to the coloured liquid, thus preparing a basic salt. In more than one recipe the lake is to be strained through linen, after the addition of the alum. Apparently, this would stop the pieces of dyewood or the grana from passing through while allowing the passage of the alumina. To understand this, we must remember the loose weaving of linen at that time. When the lake itself is to be filtered, a woollen bag is usually prescribed, shaped like the hood of a Capuchin friar. In some recipes we are told to dry the lake in the shade, and not in the sunlight, and occasionally the directions for filtering are omitted. The washing of the lake is hardly ever referred to.

In conclusion, we may sum up the methods used by saying that they consisted in boiling the dye-stuff with an alkaline solution, and precipitating the colouring matter with alum.

Passing from the methods of preparation, the substances usually used to prepare these lakes require next to be considered. A very large number of substances seem to have been used at different times for the preparation not only of rose colours but also of blue, green, and yellow lakes. For instance, Eastlake (p. 441, "Materials for a History of Oil Painting") mentions Graines d'Avignon weld, broom, curcuma, saffron, aloes, and the inner bark of various trees, as used for the preparation of yellow lakes. De Mayerne (1573-1655), a friend of Rubens, mentions a green lake prepared from buckthorn (Rhamnus Catharticus) and Hoogstraten says, "With us lakes are in use not only the purple, but the blue, green, brown, or tints of yellow lakes." These quotations are sufficient alone to show the large number of lakes in use at various periods in the history of art, and effectually disposes of those who imagine the old masters to have been confined to using a few colours only. Anyone who holds this view need only study the Tabula de Vocabulis Sinonimis et Equivocis colorum, at the beginning of the MSS. of Jehan le Begue, to abandon it at once. Nevertheless though so many lakes were known, those of most importance seem to have been the rose-coloured lakes. I shall therefore pass over my experiments on lakes from broom and from saffron, and consider only the substances used for the preparation of rose-coloured lakes, but I shall also include the preparation of lake from madder.

* From a MS. in the library of the University of Padua, date probably, the middle of the 17th century.

The rose-coloured lake prepared from ivy gum has already been considered. In the later recipes we find Indian lac, Brazil wood, and kermes repeatedly referred to. I shall begin by considering the lakes prepared from Indian lac.

It is sometimes doubtful whether the word lac or lacca refers to the red resin from India, or to ivy-juice, which is occasionally called lac, but it is evidently the Indian resin in the later manuscripts, and we find that it was imported for dyeing by the Catalans and Provençals as early as 1220. The colouring matter in this resin is due to the coccus lacca, which lives on the twigs of trees of the species Butea, Ficus, and Croton. These insects become imbedded in the resin which exudes from the tree, thus forming a red resinous mass, which is imported under the name of stick lac, and probably corresponds to the substance known as Indian lac in olden times. It is customary now, however, to soften the resin in water, when it is removed from the tree, by which the colouring matter is largely extracted, and the resin known as shellac separated. The solution of the colouring matter is then evaporated down into cakes known as lac dye. Until quite recently a considerable quantity of lac dye was sent into England, and I had some difficulty in obtaining a pound of it. The sample I obtained has been, I should think, overheated during evaporation and the colour partly burnt. As showing the identity of stick lac with the Indian lac of olden times, I may mention that it is stated in the Padua MS. already referred to, that on separating the colouring matter a colourless resin would be left behind, which could be used for making varnishes. I have prepared—(1) Some of the lac dye ground with gum; (2) a lake prepared by boiling the lac dye with a solution of soda, filtering and precipitating filtrate with alum; (3) a lake prepared by boiling stick lac with soda, filtering, and precipitating with alum. This lake may be considered to correspond closely to that used by the old masters.

Another substance largely used for preparing lakes is a dye-wood known as Verzino, Berxillium, Brexillium, Brasillium, and Brazil wood. It has long been known as a dye-wood, being mentioned in the book of "Roots," by Rabbi David Kimchi, and was called by the Arabs *albakim* or *bacam*. According to Marco Polo, the best quality grew in Ceylon. It was afterwards discovered in, and imported from, South America, and it has been suggested that Brazil takes its name from the fact of this wood being found there. No wood of this name is now imported from the East, but similar dye-woods, known as Sapan wood, Saunders wood, and Buc wood, are imported from the East, while the name Brazil wood is confined to that sent from South America. The different dye-woods are all varieties of Caesalpinia and probably the dye-woods now sent from the East are the old Verzino or Brexillium. I have prepared a lake from Brazil wood by boiling it with soda and then precipitating with alum. This is probably very similar to the lakes obtained from this wood by the old recipes.

As a rule, we expect to find that substances in favour with the old masters for the preparation of colours would yield permanent pigments; but this is not so in the case of Brazil wood, all these dye-woods yielding fugitive dyes.

We shall have to consider the question of the use of fugitive lakes when we come to treat of the mediums with which the pigments were ground.

The most famous of all red dyes is that obtained from kermes, a small insect of the same genus as the cochineal insect, and known as the coccus ilicis, which is found on the prickly oak or ilex round the coasts of the Mediterranean, the best quality coming from Arcadia. The female coccus is collected from the trees, and, as collected, looks like small scarlet berries, which crush to powder in the hand. The first mention of this dye occurs in the directions for the curtains of the Temple (Exodus xxvi. i.); and it seems to have been used from the earliest times for the production of a red dye. Prof. Middleton has shown me some pieces of cloth from the tombs in middle Egypt, dating from 300 A.D., which he believes to be dyed with kermes, and in which the colour is perfectly bright and fresh. It can be traced as a dye through the Middle Ages in the south of Europe. It was mentioned in a commercial agreement between Bologna and Ferrara in 1193; and Florence and Venice were famous for stuffs dyed with it in the 15th century.

The Italian name for the dye was *grana*, from which comes the English phrase "to dye in grain;" and Shakespeare has given his testimony to the permanency of the dye, when he makes Olivia say of her complexion "'Tis in grain, sir; 'twill endure wind and weather."

Hellot, in his "L'Art de Teinture" (1701), pages 244 and 264, says that the figures in the old Brussels tapestries, 200 years old, and

dyed with this substance, are perfectly fresh, and Bertholet states the dye to be quite permanent in his work on dyeing. It continued to be used till the introduction of cochineal from America in the 16th century, by which it was gradually replaced. Apparently Cortes first sent reports of the cochineal insect to Europe in 1523, and we find that Matthioli mentions it as quite common in 1549, and in the Padua MS. already referred to a recipe for lake is given, in which either grana or cochineal is advised to be used, showing that at that time cochineal had partly but not entirely replaced kermes. It is still used in Persia as a dye, but is no longer an article of commerce. The samples I have obtained are kindly given me by Mr. William Morris, who imports it for dyeing his finest reds for tapestry weaving. Lake prepared from it was known as "lacca di cimatura dé grana da rosato," and was almost always prepared from the clippings of the cloth dyed with kermes. In the recipe quoted we are directed to take these clippings, which apparently were the loose pieces of wool trimmed off the cloth before it left the dyer's hands, and could apparently be obtained by the painters in sufficient quantity from the dyers. I therefore asked Mr. Morris to dye a piece of cloth for me with kermes in order that I might test this method of preparing the lake.

The process of dyeing it was very simple. The cloth being mordanted with alum containing a little tartar, and then dyed in a water solution of the kermes, the whole of the kermes was absorbed by the cloth. I have boiled a piece of this cloth with soda, strained off the solution, and precipitated it with alum. The lake thus prepared does not differ appreciably from the lakes prepared from kermes direct.

The first recipe for the preparation of the lake directly from kermes that we find occurs in the "Arte Vetraria," by Neri (1612). This book, though mainly confined to the preparation of colours for staining glass, contains some recipes in the 7th book for the preparation of lakes, and in chapter 19 Neri states that, finding in Pisa, "non occorre Cimatura, non Maestra," he prepared kermes lake by boiling the kermes with a solution of alum, allowing it to stand for some days, and filtering. I find that if kermes is boiled with alum in this way, and allowed to stand, the precipitate of a rose-coloured lake is gradually formed. Some recipes also occur in the Padua MS. for the preparation of a lake direct from kermes. I have made a lake prepared by boiling kermes with soda, filtering, and precipitating with alum.

As already stated, few references to lakes prepared from madder occur. It was largely used for dyeing, and was therefore probably used for the preparation of lakes. Besides the reference to it in the MS. of S. Audemar, Theophilus refers to a substance called "menesch," which seems to be a corruption of the Indian name of the root *mnitsch*, and Neri gives a madder lake recipe in the "Arte Vetraria," book 7, chapter 118.

It is hardly necessary to collect examples for its use as a dye, but, in passing, we may mention that some of the cloth from the Egyptian tombs, already referred to, is evidently dyed with madder, the colour being perfectly preserved. That it is mentioned in the statutes of Marseilles (1287), that its cultivation was much encouraged by the Emperor, Charles V., in Holland, and that the curious regulations as to its use by the greater dyers only, show in how much esteem it was held.

In my experiments on madder lakes, I have made use of the preparation known as alizarine.

In conclusion, I would like to point out that, with the exception of madder, the lakes described are all very similar in tone of colour. I have described them as rose-coloured lakes, translating by this word the words roseli, roxita, roxeum, roxaceum, roseo, rosa, and so on. A recipe given in the Padua MS. helps us to settle what was meant by the description rose-coloured, and to confirm my belief that the lakes I have made closely resemble those made during the best period of art. The recipe is as follows:—

"*To make Brazil wood of four colours.*—Take Brazil wood, and steep any quantity you please (so that it is more than a third part) in clear water, until the colour is very red (rosso). Then divide this colour into four parts. If you wish to make a rose colour (rosato), use it pure; if you wish it purple (pavonazzo), use lime water, but the water must be tepid; if you wish a violet colour (violato), add a ley to it; and if you desire that it should be of a mulberry colour (morello), add tartar."

I have stained (1) a piece of paper with Brazil wood water, and therefore the rosato colour, which is a purplish red; (2) a piece of paper stained with Brazil wood water, rendered alkaline with soda, and therefore of the violato colour.

Even if we include madder amongst the lakes they used, they had evidently nothing which corresponded in tint to the cochineal

lakes, or so-called madder lakes used by modern artists. This, doubtless, accounts for the fact which I have been told by experts, that modern lakes cannot be used in copying the old masters.

It may be asked how the magnificent reds were produced by means of these lakes. The following quotation from the Padua MS. throws some light upon this :—

"7. The mixtures of cinnabar. The colour of ripe strawberries is imitated with cinnabar and lake. Scarlet is made (scarlato) with cinnabar, lake, and white lead. Blood colour is made with cinnabar and lake. The red colour on the cheeks of beautiful flesh is represented with cinnabar, lake, and white lead."

I have tried some experiments on this point, and find that very rich crimsons can be obtained by glazing one of these rather dull purple-coloured lakes over vermilion, and many of the rich robes in the pictures at the National Gallery can be matched in this way very well, though usually somewhat browner in tone. An interesting example of a figure just ready for such glazing is the St. John in the "Entombment of Christ" (790), apparently painted in red lead.

Examples of the purple lakes themselves can also be found in many pictures, and in various states of preservation; some very bright (see angel's robe in the Botticelli, 275), some very much faded (see the Roger Van der Weyden, 664).

The combined red produced by glazing the lake over vermilion is less likely to alter seriously with time, because the dulling of the lake is compensated for by the fading of the lake, and therefore the shining through of the vermilion. I have found, for instance, that even Brazil-wood lake, used in this way, produced a fairly durable red.

With reference to the permanence or otherwise of the lakes described above, Brazil wood fades in a few weeks, or on exposure in a south window; lac lake is half gone in a couple of months; kermes is considerably faded in twelve months, while, under the same tests, madders are unchanged. None, therefore, of these old lakes, can be recommended for re-introduction; but if a lake is required for glazing vermilion, some shades of purple madders are probably better than even kermes.

The blacks mentioned by Cennino are three in number, black chalk, a chalk prepared by charring the young shoots of the vine; a black from almond skins or peach stones; and lamp black.

Ivory black was also known, though not mentioned by him. With reference to lamp black, Vasari says that it has a tendency to darken in time, and gives this as the cause of Raphael's "Transfiguration" in the Vatican. (Page 57, vol. iii., Bohn's translation.)

It will be noticed that he mentions no browns. Brown, however, such as umber and asphaltum, were known and used. The use of asphaltum is an interesting example of how a little care can make all the difference. Many modern pictures have been spoiled by it, and artists are afraid of it. In the old recipes, however, we are directed to roast it before grinding in oil. Prof. Church, in his recent book on pigments, gives his testimony that this is perfectly successful, and the pigment may then be ground in oil and used with impunity.

Besides these colours, Cennino mentions indigo, and states that a fine green can be made by mixing it with orpiment. He probably, however, only means it to be used in miniature painting.

Having thus gone through the list of pigments given by him, it is of some interest to collect those that he regarded as safe for use in fresco. These were sinopia, amatisto, yellow ochre, Naples yellow, verde terra, bianco sangiovanni, and black. No blue is mentioned, though elsewhere he talks of using indigo, which is difficult to understand. Of these colours one is wanting from the modern palette, namely, Naples yellow. How far as safe a palette can be selected from among modern pigments I do not know. I think, however, that if blue copper frits are introduced again, or cobalt, blue used, with cobalt green and oxide of chromium green, that a fairly safe palette could be made up along with the earths given above. I have already described and shown how the purple lakes can be effectively used by glazing over vermilion, how verdigris looks over yellow ochre, and how gold can be used as a pigment.

In conclusion, beyond perhaps the Egyptian blue, I do not know of any colour which we really require to introduce from these old palettes. Many of their finest pigments either will not permanently stand modern city air, or cannot be trusted in the hands of a modern artist. In the next lecture we have to deal more fully with the method used to protect certain pigments, but enough has been said already to show that care had to be and was taken to guard against the weakness of each pigment used. This cannot be done under modern conditions, and, consequently, while

gaining many hints and much that is suggestive and useful from their study, I do not think that we have to seriously attempt to re-introduce many of them into the modern palette. What is required to make the modern palette safe is exclusion, not inclusion. It is true that many pigments were known to the old masters, many more than I have described in these lectures, yet I do not doubt that the best painters rigidly excluded most of them, and carefully selected those thoroughly proved. When they had to use lake, verdigris, or orpiment, they took especial precautions to insure its durability. It will be noticed that out of the pigments known to him, Cennino Cennini only selects seven as suitable for fresco painting.

In the next lecture we shall treat of the medium with which these pigments were mixed.

Miscellaneous.

JOURNAL OF INDIAN ART.

In the numbers of the *Journal of Indian Art* for October last, and January, 1892, Mr. William Griggs published a continuous series of illustrations of the collections of Indian art belonging to his Royal Highness the Prince of Wales, and shown at Marlborough-house and Sandringham-hall. The examples illustrated have been selected either for their artistic merit, technical skill, or sumptuary splendour; and everyone of them is a masterpiece of Indian decorative work. Mr. W. Griggs has reproduced these works in photo-chromo lithography with great success. The plate of an Ahmedabad kincob is said to be the very finest mechanical facsimile of a textile fabric that has ever been executed.

Beside these illustrations, there are others of Marlborough-house, and Sandringham, and portraits of the Prince and Princess of Wales, and a graphic table of the pedigrees of their Royal Highnesses, compiled from Mr. Burdett's work entitled "The Prince, Princess, and People."

The descriptive text is by Sir George Birdwood, and the following three extracts are taken from this.

AN "ARGHA"-SHAPED "ATAR-DAN" OF JEYPORE ENAMEL.

The round dish in Jeypore enamel [No. 66] is the largest of its kind ever produced, and took four years in making. Like all other examples of this work, it is glorious in colouring. The next object [No. 67] is interesting, from its resemblance to the "Ciborium minus,"* or pyx, in which the "Host" is kept after consecration, as "the Blessed Sacrament;" and there can be little doubt of the Mediæval Christian church having borrowed both the design and purpose of this vessel from the lotus-form *argha* or *yoni* used in the religious services of the Hindus. Ordinarily, the *argha* is shaped like a beast [*argha-patra*, cf. Argo, and "patera"], after the manner of the *cymbium* of Isis, and used emblematically as a cornucopia [horn of Amalthea], in pouring libations of milk, honey, &c., and in making offerings of grain, fruits, flowers, perfumes, &c., to the gods and the Brahmans, and to bridegrooms and other worshipful persons. But when shaped as an 8, 12, or 16-petalled lotus, folded on an inner cup, just as the flowers of the *Nelumbium speciosum* are folded on their honeycombed seed-bearing "torus," it is meant to hold and enshrine the lapilliform *lingam* [to be distinguished from the *salagrama* of Vishnu] sacred to Siva, the "Lord of the *argha*" [Argha-natha], as Mahadeva, "the Great God" over all gods. The *argha* itself always symbolises *Parvati*, "the Mountaineer," the consort of Siva. In the "Tree of Life," with its affronted guardian beasts [cherubim], we have the ultimate poetical and artistic rendering of crude ideas suggested primarily by the same physiological phenomena; and the familiar "cone pattern" on Indian shawls, kincobs, chintzes, and carpets, of which so many absurd explanatians have been attempted, is but either a phalliform lotus bud, or, as in its ultimate evolution, the "Tree of Life" growing within "the Garden of Eden," the latter still being represented archaistically, as in the so-called "vesica piscis" of Christian art.

A "KINCOB."

The last illustration [No. 77] is of an Ahmedabad kincob [Persian *kinkhwab*, Mediæval "cammoca," French *mocade*, and English "mockado," this last form of the word having been used for a mock velvet!] or brocaded "cloth of gold" † [cf: Chinese *kim*, or *kin*, "gold."] Each end of it represents a "Paradise" [Persian *firdaus*, cf: Firdausi, "the Paradisaical," from the Sanscrit *para-desa*, literally "a far-country"] set with four pots [cf: the "Venus-Gardens" of the Greeks and Romans] of the celestial [*i.e.* planetary] "Tree of Life," enclosed within its "cone" shaped "mystical almond" ["vesica"], here derived directly from the sacred lotus-bud; the whole woven in silks of the gayest colours on a stiff ground of radiant gold. The four square "Paradise"

* See also "The Kennett Ciborium," by Mr. Archibald Constable, in *The Scottish National Memorials*, Glasgow, James MacLehose and Sons, 1890. This admirable monograph has since been reprinted, with additions by Mr. Constable.

† At first these brocades or broches, *i.e.*, "embossed" stuffs, were wholly of gold, but gradually silk was introduced in their manufacture, either as a ground for the raised charging of gold, or for the variegated patterning on a ground of intercurrent gold.

is bounded by a border of lotus flowers blooming on an angularly undulating stalk, along each side of which passes an unending procession of parakeets, inwrought of red and green with the most archaic conventionality, but every one alive, and rejoicing aloud in the unclouded sunshine of their life. There is no mistaking their voice of joy, which is the distinctive note of all the best Indian art. The body of the kincob is of tawny crimson, striped with bright gold, and diapered between the bright gold stripes with alternate lotus buds and flowers ["knop and flower pattern"] of dulled gold. It is worn as a robe by the women; and beholding a high-caste Hindu lady of the Mahratta country in such glorious apparel as this, floating about her in waves of gold like a lambent aureole, Homer's familiar line of Helen is instinctively recalled to one's lips:—

> "What winning grace! and what majestic mien!
> She moves a goddess, and she looks a queen!"*

On the Use and Abuse of Tradition in Decorative Art.

I have selected these illustrations, not to tempt our English manufacturers to copy them, but to enkindle their admiration, wonder, and imagination to nobler achievements in their own industrial arts. But in protesting against our designers slavishly plagiarising Indian patterns, I do not mean that they should not receive suggestions from them as to the general forms and disposition of the ornamentation of English manufactures. The general forms belong to all the world. They have probably originated spontaneously everywhere among the artistic races of the world; and it is not possible for man, with his limited powers of invention, to get away from them, nor, indeed, is it in the least degree desirable; for one of the greatest charms of human life is the essential unity which underlies the infinite variety of its manifestations, whether in nature or art. But what our designers should do is to give just this variety, derived from local conditions and circumstances, to the few really decorative types they have inherited, in common with all the rest of the world, from the dateless past. The details, therefore, should all be of pure English origin. We rarely find the lotus flower and bud in modern Persian art, but we always find the same knop and flower pattern, which was represented in ancient Persian art, either by the lotus flower and bud, or by the leafy head of the date tree and its cluster of fruit, these forms being replaced in modern Persian art by the rose, tulip, pink, narcissus, and other native flowers of the country. The knop and flower pattern, as represented by the lotus and its bud, probably originated in Egypt, and thence passed to Assyria, and it is from the latter country that the permutations of it seen on the Buddhistic sculptures of Bharhut, Sanchi, and Amaravati were obviously derived. From Assyria and Egypt it passed into Greece and Italy, and over all modern Europe. We have, therefore, not only a right to the use of the knop and flower pattern because in its crude shape it suggests itself, like the cross and key patterns, naturally to every one, as may be seen in the first efforts of clever children in designing, but because we have inherited it historically. But what we have to do for ourselves is to quicken the decorative forms we have received from other countries, with our own national, civic, and family, and, I would add, personal life; by adapting to them our own country fruits and flowers, and animals, and our own religious and state symbols, and civic and family arms and crests, and the emblems of our own personal lives. In this way every family in England might, as is the case with the handicraft families of the East, have its own designs in carpets, curtains, wall papers, lining papers for books, and in glass and crockery, as well as in family plate. The complete nationalisation of English art in this way, under the direction of the first masters of the age, would probably, in a generation, transform us into a finished artistic race, and give our manufactures a legitimate hold on the markets of the world we might then hope to never lose again. The knop and flower pattern is conspicuously represented on the Bharhut and Sanchi sculptures by a full-faced lotus flower, alternating with lotus buds, placed end to end, so as to fill up the space between the flowers with an hour-glass-like ornament. We find this arrangement of the knop and flower pattern constantly repeated with more or less of local character, in Greek, and Roman, and modern European art. It occurs in the vestibule of Drury-lane Theatre, where its representation is almost identical with that found at Bharhut and Sanchi. It is seen on thousands of London houses, and often on London garden-walls, in which the "flower" is represented by a course of round holes in the wall, the parapet of which is supported by the hour-glass-like "knop" done in solid masonry. It is always interesting to observe these more or less literal representations of the same ancient forms. They please a learned man, and they may satisfy a cultivated man's sense of academical propriety; but they never touch the heart of any man, simple or cunning. When, however, Messrs. Wedgwood and Co. exhibited at Paris, in 1867, an earthenware dessert service, in which all the plates and dishes were ornamented with the red-tipped daisy flower and daisy bud, in the same knop and flower arrangement, every one who saw it was delighted. Nothing could be more fresh, attractive, and satisfactory in every way. The design pleased all the more because while it was of the simplest and the happiest originality, its direct historical descent from the art of Nineveh, Athens, and Rome was obvious. There is always a fascination in thus preserving our historical connection with the past; and its severance involves no less a loss in art than in social economy and politics.

* Literally:—"How awfully like she is to the immortal goddesses."

ROADS AND HIGHWAYS IN CHINA.

The United States Minister at Peking, in a recent report to his Government, says that road-making is an art which among the Chinese has never been brought to any great perfection. The explanation, probably, is that in the greater part of China proper there are waterways, natural and artificial, crossing the plains, while human labour has always been found preferable to pack-horses or other beasts of burden over narrow and circuitous mountain passes. In Southern China, at the centres of the tea trade, the long string of coolies bearing down from the hills the leaves, in deep baskets slung on poles, is a familiar sight. The transport of brick tea over the mountain roads of Syn-chuan into Thibet, a trade said to amount to £200,000 annually, is also effected by coolies, who here, on account of the steepness of the defiles, do not use carrying poles, but bear the tea on a wooden frame strapped to their shoulders. In this way they make a fifteen days' journey over mountain paths, bearing about 100 lbs. of tea each, for which service they receive about 14s. or 15s. The importance of military roads appears never to have been impressed upon the Chinese. In Northern China, where waterways are not so numerous as in the south, intercommunication has always presented serious difficulties, which no attempt has been made to overcome. Bridges have been built over some smaller streams, but are not kept in repair. The large rivers are to be crossed by ferries only, the smaller to be forded. In some places there are bridges, which are too narrow to be crossed by carts, where the mules are taken out and led singly, while the carts are carried over on men's shoulders. In times of flood there is frequently no way of crossing at all. The roads themselves, outside the cities, are merely a line of ruts across the fields. In winter, when free from rain, as they are for nine months in the year, they keep in very good condition. In summer, they are an impassable bog; and transit, except on foot, is suspended. Inside the cities some of the crowded thoroughfares are paved with massive blocks of stone. The importance of the rapid conveyance of intelligence to the centre of Government from the outside provinces has always been felt. In the days preceding the introduction of the telegraph this was accomplished by an elaborate system of post stations. These were placed some 30 miles apart, and relays of horses constantly kept in readiness for the Imperial courier. By these means despatches have been sent to distant prominent capitals at the rate of 250 miles a day. The following custom prevails with reference to the official courier service in Thibet:—The express courier from Gartok to Lhara, a distance of 800 miles, travels night and day. He is not relieved *en route*. His clothes are, says the United States minister, sealed on him, and can only be removed after the seal has been broken by the proper official. These messengers are lifted at the post station from one horse to another, and sometimes die on the way from exposure and fatigue. It is remarkable that the various systems of government and private posts should exist without leading to the construction of proper post roads and highways in China. Over some mountain roads, however, which would otherwise be impassable, considerable work has been done and money expended. In some places the paths over the passes have been simply paved for foot passengers, but in others provision has been made for the passage of carts. Most of these roads date from very remote periods, but there are occasional instances of recent construction and repair. The most important of recent improvements is the putting in order of the road through the Chü Yung Kuan, north of Peking. This is the pass leading into Mongolia from China, through the Great Wall, past the cities of Nankou and Kalgan. It is familiar to all travellers to Peking as the Nankou Pass. The work of repair here was undertaken by the Viceroy Li Kung-chang some years ago, and the road itself is said to be of the most creditable character. Drains have been made, substantial bridges built, inequalities levelled, and obstructing rocks hewn away. This new road, says the American Minister, will be of great benefit to local traffic, but particularly for the transport of the immense quantities of tea sent by Russian merchants, on camels, from Tungchou to Kiachta, *viâ* this pass.

Obituary.

Sir George Airy, K.C.B.—Sir George Biddell Airy, K.C.B., F.R.S., who died at Greenwich on Saturday, 2nd inst., in the ninety-first year of his age, was awarded the Albert Medal in 1876, "for eminent services rendered to commerce by his researches in nautical astronomy and in magnetism, and by his improvements in the applications of the mariner's compass to the navigation of iron ships." Mr. Airy entered Trinity College, Cambridge, in 1819, and was Senior Wrangler in 1823. During his tenure of the Plumian Professorship of Astronomy, to which he was elected in 1828, he acted as director of the Cambridge Observatory. He held the office of Astronomer-Royal from 1835 to 1881, and that of President of the Royal Society from 1871 to 1872. It is not necessary to register here the particulars of the late Astronomer-Royal's active and distinguished career, but it may be mentioned that on several occasions he attended the meetings of the Society and joined in the discussions. On February 11th, 1855, he presided at a meeting, when the question of the expediency of the decimalisation of British money and weights and measures were discussed.

General Notes.

CHICAGO EXHIBITION.—A communication on the participation of the Republic of Ecuador in the Chicago Exhibition, from Mr. Alfred St. John, H.B.M.'s Minister at Quito, addressed to the Marquis of Salisbury, has been forwarded from the Foreign-office to the Secretary of the Royal Commission. It is expected that the Republic of Ecuador will make a very varied and interesting exhibit. It has been allotted 3,000 feet of space, and the building to be erected will be upon the model of her building at Paris in 1889, in representation of an Inca Temple. As many of the Equatorian Exhibits at the Paris Exhibition of 1889 as can be secured will be sent to Chicago. Most of the exhibits at the National Exhibition to be held at Quito in 1892 will be sent to Madrid in 1892, and thence to Chicago in 1893.

PARIS EXHIBITION.—The *Economiste Français* publishes a detailed analysis of the receipts and expenditure connected with the Universal Exhibition of 1889, the net financial outcome of the Exhibition being a balance of about £400,000 to the good. The receipts were made up of the money paid for admission, the produce of different concessions and lettings of space, the sale of materials afterwards, the subsidy of the city of Paris, and the amount contributed by the State. There were no fewer than 125 concessions of various kinds for cafés and restaurants, which produced about £90,000, while a sum of nearly £9,000 was received for concerts, subscriptions to water and gas, the total receipts amounting to £2,000,000, or £280,000 more than the estimate for them. The receipts of the 1867 Exhibition were £1,050,000, while those for the Exhibition of 1878 did not amount to more than £927,000, including a subsidy of £248,000 from the city of Paris. Upon the other hand, the expenses of the 1889 Exhibition, which had been estimated at £1,860,000, did not amount to more than £1,600,000, while for the 1867 Exhibition they were £936,800, and for that of 1878, £2,216,000, including a sum of £560,000 spent upon the Palace of the Trocadéro. In other words, while the 1889 Exhibition left a profit of £400,000, that of 1867 gave one of only £112,000, and that of 1878, organised at the cost of the State, left a deficit of £1,268,000. It should be pointed out, however, that in 1878 there was no subsidy from the State, whereas in 1889 the State contributed £680,000, and in 1867 £240,000. —*The Times*.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock:—

JANUARY 20.—Prof. VIVIAN B. LEWES, "Spontaneous Ignition of Coal, and its Prevention." Sir FREDERICK BRAMWELL, Bart., D.C.L., F.R.S., will preside.

JANUARY 27.—F. W. EDRIDGE-GREEN, M.D., "The Scientific Value of Lovibond's Tintometer." R. BRUDENELL CARTER, F.R.C.S., will preside.

FEBRUARY 3.—T. PRIDGIN TEALE, "Dust, and How to Shut it Out." Dr. T. E. THORPE, F.R.S. will preside.

FEBRUARY 10.—E. PRICE EDWARDS, "Burning Oils for Lighthouses and Lightships." Sir LYON PLAYFAIR, K.C.B., F.R.S., will preside.

Papers, the dates of reading of which are not yet fixed:—

"The Pamirs." By Capt. F. E. YOUNGHUSBAND.

"Iceland." By TEMPEST ANDERSON, M.D.

"Ancient and Modern Art Pottery of Japan." By ERNEST HART.

"The Fisheries Department: its Position and Prospects." By J. W. WILLIS BUND.

"The Congo State." By Captain V. LOVETT CAMERON, R.N., C.B.

FOREIGN AND COLONIAL SECTION.

Tuesdays, at Half-past Four or Eight o'clock; due notice of the hour will be given:—

JANUARY 12.—ERNEST SATOW, C.M.G., "The Laos States of Upper Siam." 4.30 p.m.

FEBRUARY 16.—LEWIS ATKINSON, "The Kimberley Exhibition."

MARCH 15.—F. A. PEZET (Peruvian Consul General), "Peru."

Papers, the dates of reading of which are not yet fixed:—

"Australasia." By Sir EDWARD BRADDON, K.C.M.G.

"Newfoundland." By Sir WILLIAM WHITEWAY, K.C.M.G.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

JANUARY 21.—HERBERT JONES, "From Tien-Shan to the Pamirs—experiences on the Russo-Chinese Frontier." The paper will be illustrated by lantern slides.

FEBRUARY 11.—LORD LAMINGTON, "Recent Travels in Indo-China." Lieut.-General Sir ANDREW CLARKE, G.C.M.G., C.B., C.I.E., will preside.

MARCH 3.—Surgeon-General Sir WILLIAM JAMES MOORE, K.C.I.E., "Indian Sanitation and the International Congress of Hygiene." Major-General Sir OWEN TUDOR BURNE, K.C.S.I., C.I.E., will preside.

MARCH 24.—G. H. M. BATTEN, formerly of the Bengal Civil Service, "The Opium Question." Sir JOHN STRACHEY, G.C.S.I., C.I.E., will preside.

APRIL 7.—Dr. J. AUGUSTUS VOELCKER, "The Agricultural Needs of India."

APRIL 28.—Sir WILLIAM WEDDERBURN, Bart., "Reorganisation of Agricultural Credit in India." The Right Hon. Sir JAMES CAIRD, K.C.B., will preside.

MAY 19.—JERVOISE ATHELSTANE BAINES, C.S.I., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock :—

JANUARY 26.—WILLIAM MORRIS, M.A., "The Woodcuts of Gothic Books." Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., LL.D., M.D., will preside. The paper will be illustrated by lantern slides.

FEBRUARY 23.—J. WILLIAM TONKS, "Artistic Treatment of Jewellery: Jewel and Address Caskets."

MARCH 8.—

MARCH 29.—E. ROSCOE MULLINS, "The Decorative Uses of Sculpture." ALFRED GILBERT, A.R.A., will preside.

APRIL 12.—C. PURDON CLARKE, C.I.E., "English Brocades and Figured Silks."

MAY 17.—GEORGE T. ROBINSON, "Decorative Plaster Work" (II.). J. HUNGERFORD POLLEN will preside.

CANTOR LECTURES.

The following courses of Cantor lectures will be delivered on Monday evenings, at Eight o'clock :—

PROF. GEORGE FORBES, F.R.S., "Developments of Electrical Distribution." Four Lectures.
January 25, February 1, 8, 15.

PROF. WILLIAM ROBINSON, M.E., Assoc-M.Inst.C.E., "The Uses of Petroleum in Prime Movers." Four Lectures.
February 29, March 7, 14, 21.

BENNETT H. BROUGH, "Mine Surveying." Three Lectures.
March 28, April, 4, 11.

DR. PERCY FRANKLAND, F.C.S., "Recent Contributions to the Chemistry and Bateriolology of the Fermentation Industries." Four Lectures.
May 2, 9, 16, 23.

HOWARD LECTURES.

A Special Course of Six Lectures, under the Howard Bequest, will be delivered on the following Friday evenings, at Eight o'clock, by PROF. W. CAWTHORNE UNWIN, F.R.S., "The Development and Transmission of Power from Central Stations."
February 5, 12, 19, 26, March 4, 11.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 11 ... London Institution, Finsbury-circus, E.C., 5 p.m. Prof. Silvanus Thompson, "Complimentary and Supplementary Colours."
Medical, 11, Chandos-street, W., 8½ p.m.

TUESDAY, JAN. 12.....SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Foreign and Colonial Section.) Mr. Ernest Satow, "The Laos States of Upper Siam."
Medical and Chirurgical, 20, Hanover-square. W., 8½ p.m.
Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Wilfrid Airy, "Weighing Machines."
Photographic, 5A, Pall-mall East, S.W., 8 p.m.
Anthropological, 3, Hanover-square, W., 8½ p.m. Mrs. French-Sheldon, "Customs among the Natives of East Africa from Teita to Kilimegalia, with special reference to their Women and Children."
Biblical Archæology, 9, Conduit-street, W., 8 p.m. Annual Meeting.
Colonial Institute, Whitehall Rooms, Northumberland-avenue, W.C., 8 p.m. Profcssor Anderson Stuart, "University Education in Australia."

WEDNESDAY, JAN. 13...SOCIETY OF ARTS, John-street, Adelphi, W.C., 7 p.m. Juvenile Lecture. Prof. J. M. Thomson, "The Three States of Matter—Solid, Liquid, and Gaseous." (Lecture II.)
Manchester Geographical Society, 44, Brown-street, Manchester, Prof. T. H. Core, "Meteorology in Relation to Geography."
Photographic Club, Anderton's Hotel, Fleet-street, E.C., 8 p.m. Mr. H. E. Davis, "Glass among the Ancients."
Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m.

THURSDAY, JAN. 14...Royal, Burlington-house, W., 4½ p.m.
Antiquaries, Burlington-house, W., 8½ p.m.
London Institution, Finsbury-circus, E.C., 6 p.m. Mr. C. T. Knaus, "Some Aspects of the Reign of Terror."
Imperial Institute, University College, Gower-street, W.C., 5 p.m. Major-Gen. Sir Frederick Goldsmid, "Persia: its Language and Literature."
Electrical Engineers, 25, Great George-street, S.W., 8 p.m.
Mathematical, 22, Albemarle-street, W., 8 p.m.

FRIDAY, JAN. 15...United Service Institution, Whitehall-yard, 3 p.m. Mr. E. A. Cazalet, "The Russian Language and Literature." Part II.
Civil Engineers, 25, Great George-street, S.W., 7½ p.m. (Students' Meeting.) Mr. J. Roxburgh Sharman, "Testing and Inspecting for Commercial Purposes."
Junior Engineering Association, Westminster-palace-hotel, S.W., 8 p.m. Mr. G. V. C. Holmes, "Modern Applications of Electricity to Metallurgy."
Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.
Physical, Science Schools, South Kensington, S.W., 5 p.m.

Journal of the Society of Arts.

No. 2,043. Vol. XL.

FRIDAY, JANUARY 15, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

JUVENILE LECTURES.

On Wednesday evening, 13th inst., Professor J. M. THOMSON delivered the second of his course of Juvenile Lectures on the "Three States of Matter," in which the relation of the solid, liquid, and gaseous states to each other, and the different changes which may be observed in the action of various material substances on each other when in the different states, were fully dealt with. Professor Thomson divided his subject into the changes produced between solids and solids, solids and liquids, solids and gases, liquids and liquids, liquids and gases, gases and gases. In the first section he spoke of the mechanical adhesion of solids, passing to the physical and chemical changes which may be produced between solid substances.

Professor Thomson then demonstrated the phenomena of solution and crystallisation of solids from liquids, pointing out the variety of solvents and their action on various substances. In connection with solids and gases, he showed the phenomena of the absorption and of the occlusion of gases by solids, the last being illustrated by the occlusion of hydrogen by palladium. He demonstrated the chemical action produced between solids and certain gases.

In demonstrating the changes produced by liquids on liquids, Professor Thomson showed the phenomena of contraction, and of the production of heat on the mixing of certain liquids, and then pointed out the questions dealing with the absorption of gases by liquids, and the circumstances of temperature and pressure regulating such absorptions. The lecturer concluded by showing the various changes which are produced between gases, passing from the formation of mere mixtures of gases to the formation of new forms of gaseous matter, and finally to the formation of liquid and solid bodies by the combination of gaseous matter.

The lecture was fully illustrated by experiments.

On the motion of the CHAIRMAN (Mr. Francis Cobb), the cordial thanks of the meeting were voted to Professor Thomson for his interesting and beautifully illustrated lectures.

Professor THOMSON, in acknowledging the vote, referred to the assistance he had received from Mr. Jackson, demonstrator of chemistry at King's College, in the preparation and exhibition of the experiments.

Chicago Exhibition, 1893.

CEYLON COMMISSIONER.

The Secretary of the Royal Commission has received from the Secretary of State for the Colonies information that Mr. J. J. Grinlinton, an unofficial member of the Ceylon Legislative Council, has been appointed by the Governor Special Commissioner for the Colony.

LIVERPOOL CHAMBER OF COMMERCE.

The Liverpool Chamber of Commerce have reconsidered the decision they arrived at last month, not to act as a local committee for the Chicago Exhibition, and the Secretary has informed the Secretary of the Royal Commission, that the Chamber having rescinded their previous resolution, are now prepared to serve as a local committee for Liverpool, and to distribute information about the Exhibition in their district.

TRANSPORTATION DEPARTMENT.

The authorities of the World's Columbian Exposition have issued a pamphlet on the classification of the Department of Transportation exhibits—railways, vessels, vehicles, &c.—from which the following information is extracted:—

For the first time in the history of world's fairs, has been decided to give the science of transportation, in its broadest meaning, that attention to which its importance entitles it. The development of modern transportation has been so recent and so rapid that its significance has hardly been understood. Already its early history is, in many instances, fading away or utterly lost. Judged by their relations to the every-

day life of the world, no other industry surpasses it in utility, or equals it as a power in the progress of civilisation. Considered from the standpoint of the amount of capital invested, it overshadows every other industry. Prof. Arthur T. Hadley, of Yale College, says:—"The railroads of the world are to-day worth from 25,000 to 30,000 millions of dollars. This probably represents one-tenth of the total wealth of civilised nations, and one-quarter, if not one third, of their invested capital. It is doubtful whether the aggregate plant used in all manufacturing industries can equal it in value. The capital engaged in banking is a trifle beside it. The world's whole stock of money of every kind—gold, silver and paper—would purchase only a third of its railroads." If to the railroads we add the shipping of the world and all means of conveyance on common roads, the magnitude of the interests represented in this department of the World's Columbian Exposition may be fairly estimated.

Plan and Scope.—It is the intent of this department that it shall fully and fairly present the origin, growth, and development of the various methods of transportation used in all ages and in all parts of the world. As far as possible, the means and appliances of barbarous and semi-civilised tribes will be shown by specimen vehicles, trappings, and craft. Past history will be illustrated by relics of the earlier days. It is hoped that in the interest of historical accuracy and the preservation of important relics which are now daily passing away, the attention of the Department of Transportation Exhibits may be called, by its friends in all parts of the world, to exhibits of this kind which may and ought to be secured. The development of water craft from the crudest forms to the modern ocean steamship; of wheeled vehicles, from the first inception of the idea of the wheel to the present seeming perfection; and of that greatest of all means of transportation—the railway—will also be further illustrated by accurate models, drawings, plans, and designs in cases where the actual apparatus, appliance, or machine itself cannot be exhibited. It is the desire of this department to keep the historical feature clearly in view, and even to magnify it. By so doing, the greatest exhibition of the actual means of transportation employed throughout the world to-day will stand out in high relief by contrast; and the wonderful achievements of recent years will bear more weighty testimony to the genius of the age in which we live. The classification is intended to be reasonably full and complete, but not to enumerate by name all possible or probable kinds of exhibits. A careful perusal of it will prove suggestive and helpful to intending exhibitors. It may seem to include some things which it is difficult to show in an exhibition of this kind, but the object kept in view is to make so complete an exposition of the methods and means employed in every branch of the business of transportation, that the earnest student of the science may here find everything at his hand, without encountering the difficulties which now beset and environ such study and investigation. A grand object-lesson will be presented so clearly and impressively that a child may learn in hours and days what would otherwise require months and years. But in addition to the object-lesson, there will be a gathering of plans, designs, blanks, reports, monographs, literature, and everything appertaining in any way to "methods of abridging distance," such as has never been made before, and such as must have an appreciable effect upon future growth and development. The tendency of such collections, and the inevitable comparisons resulting, is to bring the lowest up to the level of the best, and to stimulate to an extraordinary degree both the adoption of the most improved methods, and the invention of new means.

The Building.—The building for the display of transportation exhibits is eligibly located on the western bank of the large lagoon surrounding the beautiful wooded island, which occupies nearly the centre of the Exposition. It is near the main entrance to the grounds, and convenient of access for those arriving by all routes. The building is surmounted by a cupola reaching a height of 165 feet. Eight elevators will run from the centre of the main floor to balconies surrounding the cupola at heights of 115 and 128 feet. The view from this observatory will be beautiful in the extreme, and will give visitors an excellent comprehension of the whole plan of the Exposition grounds at a glance. The architects of the building are Messrs. Adler and Sullivan, of Chicago, who are well known as the architects of the Auditorium and other great buildings. Its general architectural treatment is simple, but with exceedingly rich and elegant details. The main entrance will consist of an immense arch, decorated with carvings, bas-reliefs, and mural paintings. It will be treated entirely in gold leaf, and will be known as "the golden door." Numerous minor entrances are provided, as shown in the plans, and with them are grouped terraces, seats, drinking fountains, and statues. The interior of the building is treated much after the manner of a Roman basilica, with broad nave and aisles. The roof is in three divisions; the middle one rising much higher than the others, and its walls pierced to form a most beautiful arcaded clerestory. The main building covers a space of 960 feet in length, by 256 feet deep—but as shown in the plans, the main floor includes nearly nine acres of additional space under roof. The total floor space, including the *entre sol*, is nearly seventeen acres. A 75 feet transfer table will travel the annex, along the western line of the main building. Railway tracks will be laid in the annex at right angles to the transfer table. The heaviest locomotives and cars can be run direct from the installaton track, which runs alongside the southern end of the building, upon the transfer table which will take them to their proper tracks inside the building. The length of these tracks is such that an entire train can be

shown connected as when in actual use. When installation of heavy exhibits has been completed, the pit of the transfer table will be floored over. The annexe will open into the main building in such a manner as to afford long and striking vistas down the main avenues and aisles.

The Railway Exhibit.—A space of over eight acres is devoted to this interest. The plan adopted provides for the best possible utilisation of space. Exhibitors will have every opportunity for showing their appliances and devices to the best advantage. As far as possible, arrangements should be made by joint agreement for showing everything in its proper place and relations. Locomotive appliances can best be shown on locomotives, and the appurtenances and furnishings of cars, on cars. Specimens of standard permanent way will afford opportunity for showing track materials, tools, and all that appertains thereto in the best possible manner. It is believed that nearly all of the establishments engaged in locomotive, car, and bridge building, will be represented. A large number of the leading railways of the world will also make exhibits of their standard roadbed, track, and equipment. The opportunity thus offered for joint action is almost unlimited, and by proper placarding where necessary, every exhibit may be given proper prominence. European railway appliances and machinery have never been exhibited on any large scale alongside those used in America. It is hoped that the undoubted influence of this Exposition upon railway development in the future great markets of the world for railway material will be sufficiently appreciated to bring out the desired comparison on a large scale. Abundant and choice space has been designated and reserved for foreign countries; and every possible facility will be afforded foreign exhibitors.

Intramural Transit.—Street railways—surface, underground, and elevated—are to be shown very completely in this department. Everything relating to their permanent way and equipment is here included, with the single exception that electric motors must be shown in the Department of Electricity. Cars and other supplies for electric roads belong in this department—a division which, while seeming to be arbitrary, is evidently necessary.

Carriages and Other Vehicles for Common Roads.—A large portion of the floor space of the transportation building proper will be devoted to this display. Included in it, it is hoped to show, with heretofore unequalled completeness, all of the characteristic forms and types of wheeled vehicles, except those used on railways. The classification is to be closely maintained, and exhibits of this nature from all countries are to be shown together, so that the most interesting and instructive comparisons may be made. Harness, saddlery, and horse trappings of all kinds are here provided for. Other vehicles and conveyances, such as those used on snow, and those employing human muscle as the motive power, are also included in this classification.

Bicycles.—This most recent of all road vehicles will receive the attention to which its unequalled popularity and rapidly increasing use entitles it. No maker of "cycles" of any importance in the world can afford to miss the greatest opportunity ever offered to place his wares advantageously before millions of possible purchasers.

Aerial, Pneumatic, &c.—Transportation through the air and by means of air is yet in a comparatively undeveloped condition. Whatever is worthy in past achievements may here appear, and whatever there is of present success or future promise. Whether or not this realm is ever conquered by human ingenuity, the subject will always be a fascinating one.

Marine Transportation.—Every known method o transportation on water may be shown in this division. Small craft of all kinds may be exhibited in full size; vessels, from the nature of the case, must be shown by models. For fuller illustration, drawings, plans, and paintings will be shown. Principal attention will be given to the merchant marine. The navigation of the inland waters of the world, especially the great lakes and rivers, will doubtless be illustrated more fully than in any previous Exposition. The classification provides, also, for everything of interest connected in any way with the subject of navigation. The government of the United States will make its naval display in connection with its own building. Foreign governments, builders of vessels of war and defence, throughout the world, and manufacturers of naval supplies, are invited to exhibit in this department, and are assured of every consideration. The separate exhibit of the United States Government will not prevent a representation of its naval history and its present plans by means of models, &c., in this department.

Proceedings of the Society.

CANTOR LECTURES.

PIGMENTS AND VEHICLES OF THE OLD MASTERS.

By A. P. Laurie, M.A.
King's College, Cambridge.

Lecture III.—Delivered December 14th, 1891.

MEDIUMS.

The use of mediums can be divided into two groups, those used before and those used after the introduction of oil painting. It is a mistake, however, to suppose that oil and its properties were not known before the introduction of oil painting. Oil varnishes seem to have been known to the ancients, and are described by Theophilus. Cennini himself, a tempera

painter, describes the preparation of a drying oil and its use for painting. As we have already seen, he describes an oil varnish as a mordant for gilding, and he also states that pictures, after being painted, must be varnished.

Apparently the custom of the tempera painters was to paint with a medium of white of eggs, or yolk of eggs, or size (the paint size being made from parchment), and then varnish the finished picture.

There is one point, however, which seems to have been very generally overlooked in this connection, though it is certainly mentioned by Eastlake. It was a common practice to add the juice of the fig-tree to the white of egg. Now the fig-tree belongs to the same family as the India-rubber tree, and its juice contains caoutchouc. We are thus brought to recognise the interesting fact that caoutchouc was used as a medium for painting long before its properties were known. Doubtless the mixture of albumen and caoutchouc would make a very tough and protective medium.

Van Eyck is generally recognised as having introduced painting in oils, though he cannot have been said to have invented oil painting. Doubtless he made many little improvements which brought oil painting into general use.

The grinding of colours seems to have been done from very early times in the same way with the muller. The method is still used for small quantities of colour. It is interesting to note, however, that the Egyptians do not seem to have known of the muller. They seem to have rubbed lumps of the colour itself round the sides of a round stone basin moistened with water. The best mullers are made of porphyry.

The preparation of the linseed or walnut oil (the two oils used by the old masters) will shortly be dealt with. Besides these oils, the materials for making varnishes were juniper resin, sandarac, amber, the balsam of the silver pine, or oleo de abezzo, the balsam of the larch; and, later, mastic and other Eastern gums. I shall not trouble you with all the learned discussions as to the nature of the varnishes used. Recipes exist in plenty, and show that in the earlier varnishes these substances are dissolved in oil. Later on, in the 16th century, spirit varnishes were introduced—that is, the resins were dissolved in turpentine or natural naphtha. The main distinction between modern varnishes and the ancient varnishes is the abandonment of amber, juniper, and pine balsams, and resins, for the gums of the East. The peculiar properties of the balsam will be explained in the course of this lecture. I may say that what now follows is an investigation into the capacity of various oils and varnishes of resisting moisture, which brings us to some curious, and, I venture to think, new conclusions. Part of it has already been laid before the Society. I venture, however, to repeat it here, as it leads up to certain experiments which have been completed since the reading of that paper, and which, I think, throw further light on the methods of the old masters.

When we look at the Van Eyck, No. 186 in the National Gallery, we are at once struck with its wonderful state of preservation. The reds, probably produced by glazings of lac, or Brazil wood, or kermes lake, over a yellow or red ground, seem certainly to have slightly faded, and turned brown, when compared with fresh preparations of the same lakes made from the old recipes; but they are in a very fair condition, and the green on the wife's dress is marvellously brilliant. This green is worthy of special attention, as it seems to be agreed, among the authorities on these matters, that it can only have been produced by a glazing of verdigris, a pigment which we now know to be of a most dangerous character, turning black, and corroding and destroying other colours. The oranges in the corner are apparently painted with orpiment, another dangerous colour to use.

With reference to the reds, I have already mentioned the three lakes, which are most commonly referred to in old recipes, madder being hardly ever mentioned. Of these, Brazil wood is very fugitive, turning a dirty brownish red, and fading very much, if only exposed to sunshine for a few days. Lac lake, though better than the last, is not a permanent lake, and kermes, though better than lac, is not a permanent lake. Unfortunately these lakes, when prepared from the old recipes, are so much alike, that it is impossible to identify them on a picture. Judging, however, by these recipes, one lake is as likely to have been used as another.

In this picture, then, painted early in the 15th century, we probably have verdigris, a notoriously fugitive pigment, orpiment, a pigment very apt to change, and a lake which will fade with more or less rapidity, according to which of the three lakes above-mentioned has been used.

It cannot then be held, that the preservation

of the picture is due to the pigments used, and we must therefore look elsewhere for an explanation of its freshness.

If then the secret does not lie in the pigments it must be in the vehicle, and this leads us to consider what properties a vehicle must have to produce so remarkable an effect.

This question is very easily answered.

It has been again demonstrated by Prof. Russell and Captain Abney, in their report on water-colours (1888) that most fugitive pigments are permanent if protected from moisture, and a still larger number, if protected both from air and moisture. If, then, we can obtain a vehicle which will really protect the particles of the pigment from moisture, we may use with safety many pigments that are now regarded as fugitive.

At this point, one is apt to think that the inquiry is concluded, as we are accustomed to assume that ordinary varnishes and oils do preserve surfaces from the action of moisture; but, unfortunately, if a sufficiently delicate test is applied, this is not found to be so. The method I have devised for doing this is to use as a pigment ignited sulphate of copper, which is of course a very hygroscopic body. If we grind a little of the ignited sulphate with linseed oil, and paint it out on a glass slide, we get an enamel-like white surface, with sometimes a slight greenish tinge in it.

If this is placed in a dessicator to dry, it remains the same in appearance. If, however, when dry it is exposed to the air of a room, it gradually turns green and transparent; or, if it is exposed under a bell jar, beside a dish of water, the change takes place much more rapidly, twelve hours being often sufficient. If we now examine the slide under a microscope, we usually find that no definite crystalline formation is visible; but occasionally, here and there, are to be found complete crystals of sulphate of copper, due apparently to a slow aggregation of molecules in the colloid linseed oil.

I shall begin by describing the experiments I have made on linseed oil alone.

Linseed Oil.

The linseed oil of modern commerce differs in several important particulars from that used by the old masters. Hot pressed from adulterated seed, refined by the addition of sulphuric acid, and then probably further adulterated with other oils before it is put on the market, it is a very inferior product. The oil of the old masters seems to have been cold pressed from pure seed, and then refined by exposure to sunlight and washing with water.

In converting it into boiled oil, various substances and methods were used; such as exposure merely to the sun till it thickened; boiling with bone ashes and pumice; boiling it with ignited sulphate of zinc*; boiling it with litharge or with white lead, or with amber; or exposing it to the sun in leaden dishes, or mixed with white lead.

The modern practice is probably in many cases similar, salts of manganese having been added to the list, and such substances as sulphate of zinc having been abandoned.

My impression from the study of the old recipes is that, probably in most cases, litharge, or white lead, was used, just as it is most commonly used now. We have, then, to look rather to the earlier stages of the preparation of the oil, to find any serious difference between ancient and modern practices.

With a view to finding whether the capacity of linseed oil for resisting moisture would be improved by following any of the old methods, I tried the following experiments. I obtained—

1. A sample of ordinary pale drying oil of the best quality.

2. A bottle of drying oil from one of the leading firms of artists' colourmen.

3. A sample of Bell's medium from Messrs. Bell and Co., of Oxford-street. This medium is prepared by cold pressing carefully sifted seed, and then keeping the raw oil at a temperature of about 100° C. for some weeks, until it becomes thick and viscous. This "fat oil" is then thinned with oil of spike for use.

4. I obtained some raw oil, cold pressed from sifted English seed, which I then refined in the following manner:—A bottle was filled one-third full with salt water and sand, and one-third full of oil, and was placed in the sun, with a loose cap over the top, for four weeks. By the end of that time no more precipitate was formed, and the oil was drawn off, filtered, and converted into boiled oil by heating to 100° C. for 120 hours with borate of manganese.

Another portion, after refining, was converted into boiled oil, by heating strongly for three hours with bone ashes, adding ignited sulphate of zinc, and allowing it to settle and stand in the sun, according to an old German recipe which is quoted by Eastlake in his "History of Oil

* The use of this substance is probably accounted for by the fact that the crude sulphate prepared from the ore often contains manganese. The pure sulphate has no effect on the oil.

Painting." Slides were painted out with these different oils mixed with sulphate of copper, and after having been dried in a dessicator were exposed to moisture. They all turned green at approximately the same rate, and repeated experiments did not show that one had much advantage over another. If a slide is varnished with oil after being dry, it of course resists a little longer; but four layers of such varnishing only protect the slide for three days instead of one.

As far, then, as these experiments are concerned, there seems to be no reason to suppose that the pure oil, sun-refined, has much advantage over the commercial oil, or that the different methods of converting it into boiled oil exercise an appreciable effect. Only one point seemed to remain unsettled. It seemed possible that the old oil, imperfectly pressed, might be superior to that obtained by the hydraulic press. In order to test this, I had some fresh seed pressed, and took samples during the pressing, dividing the oil into three parts. Taking the first of these, I refined it, boiled it with borate of manganese, and tested it. The moisture penetrated through it as before.

These experiments seem to show, then, pretty conclusively, that linseed oil, no matter how pure, or how carefully refined, or in what way it is converted into boiled oil, cannot be depended upon to protect a surface from moisture. In the course of these experiments, I was struck with the fact that linseed oil which had been kept for some time, after it was dry in the dessicator, seemed to resist better than lately-dried oil, when exposed to moisture. Three weeks was found to make a considerable improvement, and two months still further improvement. These experiments are being continued, with a view to finding at what point the improvement will cease.

When we consider the nature and constitution of linseed oil, I do not think we need be surprised at its permeability to moisture. Besides containing linoleine, it also contains considerable quantities of non-drying fatty acids, which, being unaltered during the oxidation of the linoleine, must tend to produce a spongy and porous surface. According to Allen, the dried film contains free glycerine, which must not only tend to increase its porosity, but also to act as a carrier of moisture. Taking these different facts into consideration, the passage of moisture through linseed oil is not surprising.

I should like to refer here to a theory which has been recently advanced, that lead driers are injurious in pictures, on account of the formation of lead soaps. As far as these experiments are concerned, we have no confirmation of this; and I confess that the theory seems to me a very startling one, in the light of the fact that the white lead used by the old masters was prepared by the Dutch process, and therefore contained large quantities of lead hydrate, and of the fact that the oldest recipe I am familiar with for preparing drying oil, advises that this should be done by boiling with oxide of lead.

When Mr. Scott Taylor tells us that the Venetian painters were accustomed to grind their white lead repeatedly in vinegar, I can only suppose that chemists, like poets, are sometimes caught nodding. It seems to me more probable that treatment with lead salts may remove some of the fatty acids other than linoleic acid as lead soaps. I do not find, however, that the oil which rises to the surface of ground white lead protects from moisture any better than ordinary oil.

Walnut Oil.

Walnut oil is frequently referred to in the old recipes, and seems to have been largely used by the old masters for painting. It can be prepared by pressing the kernels of walnuts after slightly warming them. The walnuts should be about three months old. The oil obtained is very pale, and dissolves white lead freely on boiling, becoming darker in colour. I prepared a little by boiling the kernels of the walnuts with water, after pounding them in a mortar, roughly separating the oil which rose to the top, dissolving the oil in ether, filtering, and evaporating off the ether. I then converted this oil into a boiled oil, by heating it with white lead. On testing it with the sulphate of copper, I found that moisture rapidly penetrated, showing that it is no better in this respect than linseed oil. As these were the two oils which were used by the old masters, the protection of their pigments cannot have depended upon the nature of the oil used.

Resins.

In order to test how far pure resins will protect the sulphate of copper from moisture, I dissolved them either in spirits of turpentine or in benzole, ground the sulphate of copper with the solution, and painted it out on a glass slide. I have not attempted an exhaustive examination of resins, but have contended myself with a few typical ones, namely, colophony, mastic, Sierra Leone copal, and amber. The

varnishes were all prepared by first fusing the resin, and then gradually adding the spirits of turpentine to the fused mass.

The change of appearance on exposing one of the slides thus prepared to moisture was quite different to the appearance in the case of oil. The surface became an opaque greenish blue in the course of a few hours in the case of colophony, mastic and Sierra Leone copal, but after that there was no further change. On then examining these slides under the microscope this appearance was explained. The whole surface was rough and covered with blue cones of sulphate of copper with unaltered white plains between. Apparently the varnish on drying became full of small cracks or holes, through which moisture penetrated, but in itself resisted the passage of moisture. These holes were so close together as to give the whole surface a blue appearance when examined with the naked eye. The one exception to this was the amber varnish. It resisted the attacks of moisture for weeks without change. I think, however, that we may consider that such solutions of resins protect a surface from moisture sufficiently well for all practical purposes. The slight change taking place in the sulphate of copper does not go any further, and would, I think, be imperceptible in the case of a fugitive pigment.

I need hardly point out, however, that such solutions are quite unfit to be used as mediums in place of oil, and that the surface formed is brittle and not very durable.

Oleoresinous Vehicles.

Eastlake, in his "History of Oil Painting," devotes himself principally to trying to determine what medium was used by Van Eyck and his immediate followers. As his book is the most important work on this subject, and he has devoted immense pains to investigating all the documentary evidence, the theory he advances requires specially careful examination.

Briefly, his theory is this, that the Flemish painters ground their colours in oil, that they prepared a varnish by dissolving a resin, preferably amber, in oil, and that they mixed a little of this with the colour. He claims that such a medium protects the pigments from moisture, and that it is only necessary in the case of specially fugitive pigments such as yellow lake, verdigris, &c., to increase the proportion of varnish, and diminish the proportion of oil, in order to effectually lock them up and protect them from the action of a moist climate. This he calls the oleoresinous vehicle, and while, undoubtedly, showing that this in all probability represents their usual practice for ordinary pigments, I think he fails to make out that they relied upon this method in the case of notoriously fugitive pigments. In fact, curiously enough, as I shall presently show, any evidence he brings forward points in quite a different direction. At the same time he quotes from a sufficient number of authorities to show that he correctly describes their general practice; a practice for which there are sufficient reasons, apart from the question of the preservation of specially fugitive pigments.

It has been shown by Professor Church that even so hard a resin as copal, when dissolved in a volatile medium, after a year becomes covered with minute cracks; that this is also true of copal dissolved in the usual quantity of oil necessary to make a varnish. But he finds that if a copal oil varnish is fixed with a certain proportion of oil, it forms a surface which is hard, and therefore preferable to oil alone, which is soft, but which does not crack. There seems to be no doubt, therefore, that, apart from other considerations, the mixture of a resin dissolved in oil, with oil, produces the most permanent surface. It remains to be seen whether such a medium has the quality claimed for it by Eastlake of protecting the pigments from moisture.

In order to experiment upon this matter, I obtained (1) a very fine sample of a genuine copal varnish from Messrs. Freeman. (2) Mander Brothers, Coburg varnish. (3) I dissolved Sierra Leone copal in my own pure linseed oil, and heated it till it became stringy, as directed in the old recipes. (4) I dissolved amber in the same way in the pure oil. (5) I boiled some of the amber varnish, mixed with white lead till almost solid, and then diluted it with spirits of turpentine. I then prepared slides with these varnishes mixed with the sulphate of copper.

Comparing the slides painted with pure oil with slides painted with a mixture of oil and varnish, and slides painted with the varnish alone. In some cases, the slides, after drying, were varnished with the mixture that had been used in painting them out. In making these varnishes, I mixed about one-third resin with about two-thirds oil. None of these preparations resisted the attacks of moisture. Those containing varnish resisted a little longer than those merely containing oil; but the difference

was probably due to the greater thickness of the protecting layer.

As far, then, as we can judge, by the sulphate of copper test, Eastlake's theory that an oleoresinous vehicle will protect a fugitive pigment is not correct. It seemed to me necessary, however, to check these results by some experiments made in another way, and I therefore determined to try whether such mediums would protect a fugitive pigment.

In order to reproduce, as near as possible, the conditions necessary in the case of one of the old masters, I prepared some Brazil wood lake according to one of the old recipes, and, after careful washing and drying, ground it with the following mediums :—

1. Commercial pale boiled oil.
2. Rowney's boiled oil.
3. My pure oil.
4. The pure oil mixed with amber varnish.
5. The pure oil mixed with copal varnish.

All of these faded when exposed to sunlight, and apparently faded at the same rate.

To confirm this result, I next rubbed out on two glass plates carmine ground in pure oil. After the two plates were dry, I put one away in the dark and exposed the other to light. At the same time, I rubbed out on two other plates, carmine ground with pure oil and a little amber varnish, and exposed one of these to light. The two plates kept in the dark retained their brilliancy, while the two exposed to light quickly turned brown at the same rate.

I think that these experiments show pretty conclusively that whatever method may have been used to preserve fugitive pigments by the old masters, it cannot have been that of grinding colours with oil, and then mixing in a little oil-varnish, as supposed by Eastlake.

In order, then, to solve this problem as to the nature of the vehicle used to preserve fugitive colours, it is necessary to lay aside the theories of such writers as Eastlake, and examine carefully such old recipes as are available. This is all the more necessary as the word varnish is used so carelessly by writers on this subject, for they seem to think that all varnishes have similar properties, and therefore it does not matter whether the nature of the varnish is stated or not. To begin with, the oldest recipes we find—the varnishes—three mentioned are all oil varnishes. Besides oil, they contain amber, or sandarac, and a balsam, such as Venice turpentine (the balsam of the larch), or oleo de abezzo (the balsam of the silver pine). Very large quantities of these balsams were sometimes used. For instance, in one old recipe a varnish is recommended consisting of three parts Venice turpentine, three parts of oil, and one part of mastic; while in another recipe two parts of Venice turpentine to one part of oil is given. Such varnishes must be considered simply as balsams, slightly diluted with oil to make them flow better and give greater toughness to the surface. In other cases the varnishes do not contain these balsams.

Apparently the first spirit varnishes, by which I mean in this case varnishes formed by dissolving a resin or a balsam, or both, in spirits of turpentine or natural naphtha, were invented in Italy, and thence found their way back to Flanders, the first home of oil painting; but the records that have been left of the methods used by Van Eyck and his followers are so scanty, that we cannot speak with certainty on this point.

The first detailed account that we get of the methods of the Flemish painters is that given by De Mayerne, physician at the Court of Charles I., and a friend of Rubens and Vandyke. In the recipes given by him, Venice turpentine is frequently mentioned as a suitable substance for the preparation of varnishes, and he advises that it should be dissolved either in naphtha or spirits of turpentine, with the occasional addition of mastic, or with the addition of a few drops of oil to give it toughness.

Perhaps the most interesting of his recipes is the one in which he tells how verdigris can be preserved for ever without changing by heating it with Venice turpentine and spirits of turpentine.

The Italian painters seem to have preferred oleo de abezzo, as lighter in colour and quicker in drying, and in one of the recipes given in the Paduan MS. it is stated that amber can be dissolved in such a balsam. Apparently, in the time of Rubens, the custom had grown up in Flanders of varnishing pictures after they were finished, which was not done in the days of Van Eyck. Doubtless, therefore, the varnishes mentioned by De Mayerne in many cases are meant for covering finished pictures, but the recipe for preserving verdigris looks as if they were sometimes used for mediums. To carry down the tradition as to the use of Venice turpentine, it is only necessary to refer to the canvas of Sir Joshua Reynolds, in the possession of the Royal Academy, where the dab of paint labelled

gamboge, plus Venice turpentine, is perfectly fresh, while the dab labelled gamboge plus oil has completely faded. Many other examples as to the use of balsams might be quoted, but sufficient has been said to show the necessity of investigating the properties of such substances.

I have experimented upon three balsams, Venice turpentine*, Canada balsam, and the balsam of the silver pine. On testing with sulphate of copper, I found that Venice turpentine completely secluded moisture. Canada balsam did so for a long time, several weeks, but seemed to slowly yield. I have not tested oleo de abezzo in this way. When used as mediums, the addition of a very little oil, about quarter of the weight of the balsam, suffices to make it thin enough to grind colours in. Hard resins, such as amber and copal, readily dissolve in them, thus forming compound varnishes. The best picture varnish I have been able to make is copal dissolved in Venice turpentine and diluted with turps or with naphtha.

The oleo de abezzo is a beautiful pale yellow balsam, and forms a varnish quite equal to mastic, with, however, a slight tendency to bloom. They are all brittle when dry, but a very small admixture of oil gives the necessary toughness.

I find that carmine, ground in Venice turpentine or in oleo, with a few drops of oil, preserves its freshness wonderfully. On exposure to sunlight the purple bloom quickly goes, but after that the colour remains strong and good, while becoming a dirty brown and fading in oil or an oil varnish. I find that if verdigris in oil be exposed to sulphuretted hydrogen gas it turns black in a few minutes, while verdigris in balsam is only very slightly affected after some hours.

There is another important property revealed by these balsams which requires some explanation. I find that certain pigments dissolve more or less readily in linseed oil. For instance, emerald green dissolves slightly, and diffuses through the oil even after it is dry. If, for instance, emerald green is painted over dry cadmium yellow with a layer of dry oil between, it gradually passes through, and after a few months attacks the cadmium yellow and turns it black.

* I obtained a sample of genuine Venice turpentine with some difficulty in London. Through the kindness of the Curator of the Cambridge Botanical-gardens I obtained some larch balsams from trees there, and some balsam of the silver pine from the Black Forest.

Verdigris is still more soluble. If warmed with linseed oil it gives a green solution. If verdigris in oil and cadmium yellow are mixed together, the action of the verdigris is so rapid that in a few hours the whole thing has turned black. Now, if instead of oil these pigments are ground in a balsam, even though a few drops of oil are mixed with it, this does not happen. A light green can be made with them perfectly well, which, as far as I have tested it, is durable.

I hold then that both the historical and experimental evidence shows that these balsams were used for varnish and mediums, in some cases being used pure or almost pure. The point to be noted is that the harder the resin, the more oil is required to dissolve it and make a fluid varnish. Consequently amber was unsuitable for the preservation of pigments such as verdigris. On the other hand, for other purposes, amber may have been used. With amber, sandarac, and the balsams, a whole range of varnishes could be easily prepared, suitable for different purposes, the first of the series containing a great deal of oil, the last being nearly pure resin. In fact, in some recipes I find the hot balsams recommended as a varnish by itself; and in one old recipe balsams are mentioned by themselves, as the right tempera for colours. The evidence of Dr. Mayerne is also very conclusive on this point, especially in his recipe for the preparation of verdigris; and this theory is certainly borne out by the appearance of the old Dutch and Flemish pictures. Probably the use of balsam was more excessive in the Flemish pictures than in the Italian pictures meant for a drier climate.

You will ask, if this theory of mine is correct, how does it apply to modern painting?

I do not, as yet, see how to apply it. These balsam vehicles are sticky, and quite unsuitable therefore for modern work. I think, however, that it indicates to us very clearly the direction in which to work, to improve our present oil mediums. I shall, at present, continue my experiments on varnishes prepared from fine resins and balsams. The varnish I have used for the gilding of the tinfoil has been prepared on these lines. I find that the melted balsam not only dissolves amber, but also dragon's blood, saffron, and aloes, and, I do not doubt, will protect them from change. Much, however, requires to be done before a satisfactory varnish can be prepared from them.

In the course of these three lectures I have

said something on panels, on pigments, and on vehicles. I have purposely said nothing on canvases, as I do not feel competent at present to discourse about them. Nor have I exhausted the list of ancient pigments. I have confined myself to those of most importance.

I think you will feel with me that no royal road has been discovered by which durable pictures can be painted. On the other hand, I think you must have been impressed by the marvellous amount of ingenuity expended on this question by the old masters, and the skill with which they handled it.

Many hints, useful practical hints, may be derived from their practice, but it cannot be applied directly to modern work. The conditions are entirely different. The artist of to-day must have his pigments ground so that they are perfectly free under the brush, and he must be able to mix them without a thought as to how far they are compatible one with another. His picture is an inspiration, it is not slowly and carefully built up, he refuses to be trammeled by the traditions of the house painter. Consequently, he throws upon the chemist the burden of solving a problem much more difficult than the one of the past.

The first step is, I believe, rigid exclusion of dangerous pigments, and careful preparation of those retained. The next is careful preparation of the oil and the varnish used.

I find oil properly prepared stands wind and weather better than that usually sold. Exposure for twelve months, without varnish, outside, and to all the sun and rain, &c., does not seem to hurt it. The oil with which pigments are usually ground does not stand such a test. In this oil a suitable resin should be dissolved to make a varnish.

So much decided on, we can begin our search for an improved medium. A medium that will isolate the pigments one from another, and protect them from external influence, as the balsams do, and at the same time work freely beneath the brush. This is, I think, the main problem before us.

FOREIGN & COLONIAL SECTION.

Tuesday, January 12, 1892; Sir THOMAS WADE, G.C.M.G., K.C.B., in the chair. The paper read was "The Laos States of Upper Siam," by Ernest Satow, C.M.G.

The paper and discussion will be printed in the next number of the *Journal*.

Obituary.

EARL OF LICHFIELD.—Thomas George Anson, second Earl of Lichfield, died at his town house on Thursday, 7th inst., aged 67. He was, for a time, Member of Parliament for the city of Lichfield, and succeeded to the Earldom on the death of his father in 1854. In the early stages of the reformatory movement, originated in Birmingham by the late Matthew Davenport Hill, Lord Lichfield took an active part in the formation of public opinion on the question. He was the first chairman of the Society for the Reformation of Juvenile Offenders, and took part with Lord Norton (then Sir Charles Adderley) and others in establishing the reformatory at Saltley. Lord Lichfield was elected a Member of the Society of Arts in 1867, and held the office of Vice-President in 1871.

General Notes.

CHICAGO EXHIBITION.—The New Year's number of the *Chicago Herald* (Friday, Jan. 1) contains a paragraph on the Columbian Exposition in all living languages, including Persian, Arabic, Turkish, Armenian, modern Greek, Chinese, Japanese, Hindostani, Syriac, &c. This number also contains illustrations of the condition of the various buildings in the grounds as they appeared on December 22, 1891.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock:—

JANUARY 20.—Prof. VIVIAN B. LEWES, "Spontaneous Ignition of Coal, and its Prevention." Sir FREDERICK BRAMWELL, Bart., D.C.L., F.R.S., will preside.

JANUARY 27.—F. W. EDRIDGE-GREEN, M.D., "The Scientific Value of Lovibond's Tintometer." R. BRUDENELL CARTER, F.R.C.S., will preside.

FEBRUARY 3.—T. PRIDGIN TEALE, "Dust, and How to Shut it Out." Dr. T. E. THORPE, F.R.S., will preside.

FEBRUARY 10.—E. PRICE EDWARDS, "Burning Oils for Lighthouses and Lightships." Sir LYON PLAYFAIR, K.C.B., F.R.S., will preside.

FEBRUARY 17.—Capt. F. E. YOUNGHUSBAND, "The Pamirs."

Papers, the dates of reading of which are not yet fixed:—

"Iceland." By TEMPEST ANDERSON, M.D.

"Ancient and Modern Art Pottery of Japan." By ERNEST HART.

"The Fisheries Department: its Position and Prospects." By J. W. WILLIS BUND.

"The Congo State." By Captain V. LOVETT CAMERON, R.N., C.B.

"Durability of Pigments Ground in Oil and other Vehicles." By A. P. LAURIE, M.A.

"Manufacture and Industrial Application of Flexible Tubing." By GILBERT R. REDGRAVE.

FOREIGN AND COLONIAL SECTION.

Tuesdays, at Half-past Four or Eight o'clock; due notice of the hour will be given:—

FEBRUARY 16—LEWIS ATKINSON, "The Kimberley Exhibition." 8 p.m. The paper will be illustrated by lantern slides.

MARCH 15.—F. A. PEZET (Peruvian Consul General), "Peru."

Papers, the dates of reading of which are not yet fixed:—

"Australasia." By Sir EDWARD BRADDON, K.C.M.G.

"Newfoundland." By Sir WILLIAM WHITEWAY, K.C.M.G.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

JANUARY 21.—HERBERT JONES, "From Tien-Shan to the Pamirs—experiences on the Russo-Chinese Frontier." Sir WILLIAM W. HUNTER, K.C.S.I., C.I.E., LL.D., will preside. The paper will be illustrated by lantern slides.

FEBRUARY 11.—LORD LAMINGTON, "Recent Travels in Indo-China." Lieut.-General Sir ANDREW CLARKE, G.C.M.G., C.B., C.I.E., will preside.

MARCH 3.—Surgeon-General Sir WILLIAM JAMES MOORE, K.C.I.E., "Indian Sanitation and the International Congress of Hygiene." Major-General Sir OWEN TUDOR BURNE, K.C.S.I., C.I.E., will preside.

MARCH 24.—G. H. M. BATTEN, formerly of the Bengal Civil Service, "The Opium Question." Sir JOHN STRACHEY, G.C.S.I., C.I.E., will preside.

APRIL 7.—Dr. J. AUGUSTUS VOELCKER, "The Agricultural Needs of India."

APRIL 28.—Sir WILLIAM WEDDERBURN, Bart., "Reorganisation of Agricultural Credit in India." The Right Hon. Sir JAMES CAIRD, K.C.B., will preside.

MAY 19.—JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock:—

JANUARY 26.—WILLIAM MORRIS, M.A., "The Woodcuts of Gothic Books." Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., LL.D., M.D., will preside. The paper will be illustrated by lantern slides.

FEBRUARY 23.—J. WILLIAM TONKS, "Artistic Treatment of Jewellery: Jewel and Address Caskets."

MARCH 8.—

MARCH 29.—E. ROSCOE MULLINS, "The Decorative Uses of Sculpture." ALFRED GILBERT, A.R.A., will preside.

APRIL 12.—C. PURDON CLARKE, C.I.E., "English Brocades and Figured Silks."

MAY 17.—GEORGE T. ROBINSON, "Decorative Plaster Work" (II.). J. HUNGERFORD POLLEN will preside.

CANTOR LECTURES.

The following courses of Cantor lectures will be delivered on Monday evenings, at Eight o'clock:—

PROF. GEORGE FORBES, F.R.S., "Developments of Electrical Distribution." Four Lectures.

LECTURE I.—JANUARY 25.—Low pressure supply—Comparison between 1885 and 1892—Central stations *versus* isolated plants—Electricity *versus* gas—Cost of feeders and distributing mains—Management of feeders—Use of recording apparatus—House wiring—Three-wire system—Five wires—Use of motor-dynamos as compensators—Batteries—Conductors.

LECTURE II.—FEBRUARY 1.—High-pressure supply—Old attempts—Alternate currents—Transformers—Feeders—Sub-stations—Overhead and underground conductors—Generation of electricity by power obtained at a distance from (1) electricity, (2) gas, (3) compressed air, (4) water under pressure—Load factor—Waste products.

LECTURE III.—FEBRUARY 8.—Transmission and distribution of electricity derived from lighting circuits—Effect on load factor—Separate circuits for power—Distribution for street and other railways—Utilisation of water-power by electric transmission to a distance.

LECTURE IV.—FEBRUARY 15.—Generators of electricity by water-power and by steam obtained from destructors—General account of destructors—Hydraulic accumulators—Utilisation of local circumstances—Probable developments of electric distribution in the immediate future.

PROF. WILLIAM ROBINSON, M.E., Assoc-M.Inst.C.E., "The Uses of Petroleum in Prime Movers." Four Lectures.
February 29, March 7, 14, 21.

BENNETT H. BROUGH, "Mine Surveying." Three Lectures.
March 28, April, 4, 11.

DR. PERCY FRANKLAND, F.C.S., "Recent Contributions to the Chemistry and Bateriology of the Fermentation Industries." Four Lectures.
May 2, 9, 16, 23.

HOWARD LECTURES.

A Special Course of Six Lectures, under the Howard Bequest, will be delivered on the following Friday evenings, at Eight o'clock, by PROF. W. CAWTHORNE UNWIN, F.R.S., "The Development and Transmission of Power from Central Stations."

February 5, 12, 19, 26, March 4, 11.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 18...Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. E. H. Morris, "The Four-Course System, with desirable Variations."

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

British Architects, 9, Conduit-street, W., 8 p.m. 1. Discussion on "Amended Suggestions for the Conduct of Architectural Competitions." 2. Address to Students, by Mr. J. Macvicar Anderson, President.

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 1A, Adelphi-terrace, W.C., 8 p.m. Mr. W. J. Slater, "The Weak Side of Natural Selection."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. E. B. Tylor, "Recent Information as to the Lower Races of Man."

TUESDAY, JAN. 19....Royal Institution, Albemarle-street, W., 3 p.m. Professor V. Horsley, "The Brain." (Lecture I.)

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. Wilfrid Airy's paper, "Weighing Machines."

Statistical, Geological Museum, Jermyn-street, S.W., 7¾ p.m. Mr. L. L. Price and Dr. J. C. Steel, "The Recent Agricultural Depression, as exhibited in the rental of an Oxford College, and the financial position of a leading London Hospital."

Pathological, 20, Hanover-square, W., 8½ p.m.

WEDNESDAY, JAN. 20...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Prof. Vivian B. Lewes, "Spontaneous Ignition of Coal, and its Prevention."

Meteorological, 25, Great George-street, S.W., 7 p.m. Annual Meeting.

Geological, Burlington-house, 8 p.m. 1. Rev. Edwin Hill and Prof. T. G. Bonney, "The Hornblende-schist, Gneisses, and other Crystalline Rocks of Sark." 2. Arthur Wm. Walters, "North Italian Bryozoa.—Part II. Cyclostomata."

Microscopical, 20, Hanover-square, W., 8 p.m. Annual Meeting. Address by the President, Dr. R. Braithwaite.

Photographic Club, Anderton's Hotel, Fleet-street, E.C., 8 p.m. Mr. J. Nesbit, "Stereoscopic Photography."

Entomological, 11, Chandos-street, W., 7 p.m. Annual Meeting. Address by the President, Mr F. D. Godman.

Archælogical Association, 32, Sackville-street, W., 8 p.m.

Patent Agents, 55, Chancery-lane, W.C., 7½ p.m. 1. Discussion on Mr. Abel's and Mr. Loubier's papers. 2. Mr. A. V. Newton, "Patent Agency: its Origin and Uses." 3. Mr. G. B. Ellis, "Compulsory Licenses."

Civil and Mechanical Engineers, 7, Westminster Palace Hotel, S.W., 7 p.m. Mr. H. Coward, "Forced Ventilation by Compressed Air."

Inventors' Institute, 27, Chancery-lane, W.C., 8 p.m.

THURSDAY, JAN. 21 ... SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Mr. Herbert Jones, "From Tien-Shan to the Pamirs: Experiences on the Russo-Chinese Frontier."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8 p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. D. Morris, "Additional Notes on the Tick Pest in Jamaica." 2. Mr. F. E. Weiss, "The Development of Caoutchouc-containing Cells of Eucommia Ulmoides, Oliver." 3. Dr. Jean Muller, "The Lichens of Manipur."

Chemical, Burlington-house, W., 8 p.m. 1. Mr. M. A. Adams, "The Estimation of Oxygen in Water." 2. Messrs. P. F. Frankland and W. Frew, "A Pure Fermentation of Manitol and Dulcitol." 3. Prof. V. B. Lewes, "The Luminosity of Coal-gas Flames." 4. Mr. W. Ostwald, "The Magnetic Rotation of Dissolved Salts." 5. Mr. W. Ostwald, "The Dissociation of Liquid Nitrogen Peroxide."

London Institution, Finsbury-circus, E.C., 7 p.m. Mr. Carl Armbruster, "The Wagner Festival Performances at Bayreuth." (With illustrations.)

Royal Institution, Albemarle-street, W., 3 p.m. Dr. A. S. Murray, "Some Aspects of Greek Sculpture in Relief." (Lecture I.)

Numismatic, 22, Albemarle-street, W., 7 p.m.

FRIDAY, JAN. 22 . United Service Institution, Whitehall-yard, 3 p.m. Colonel Gouraud, "The Phonograph for Naval and Military Purposes."

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m. Lord Rayleigh, "The Composition of Water."

Philological, University College, W.C., 8 p.m.

Physical, Science Schools, South Kensington, S.W., 5 p.m. 1. Prof. G. T. FitzGerald, "The driving of Electromagnetic Vibration by Electromagnetic and Electrostatic Engines." 2. Prof. S. P. Thompson, "Supplementary Colours."

SATURDAY, JAN. 23 ... Saturday Lecture Society, Lecture Theatre, South Kensington Museum, S.W., 3 p.m. Prof. A. W. Rücker, "Electricity and Light." (Lecture II.)

Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.

Royal Institution, Albemarle-street, W., 3 p.m Prof. J. R. Fleming, "The Induction Coil and Alternate Current Transformer."

Journal of the Society of Arts.

No. 2,044. Vol. XL.

FRIDAY, JANUARY 22, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

H.R.H. THE DUKE OF CLARENCE AND AVONDALE, K.G.

At their meeting on Monday, the 18th inst., the Council of the Society resolved that the following letter be addressed to H.R.H. the Prince of Wales, the President of the Society:—

To H.R.H. The Prince of Wales, K.G.,
President of the Society.

Sir,—The Council of the Society of Arts desire on their own behalf, and on behalf of the Society over which you have presided now for twenty-eight years, to express to your Royal Highness the feeling of profound sorrow with which they have received the sad news of the death of His Royal Highness the Duke of Clarence and Avondale.

His Royal Highness had been, since 1885, a Vice-President of the Society, and the Council had every reason to hope that, in years to come, he might have co-operated with them in carrying on the many works of public utility, for the promotion of which the Society was established, and that they might have received from him the same judicious guidance, the same wise counsel, that they have received from your revered father, and from yourself.

These hopes have been shattered by his sudden and untimely death, and there remains to the Council but the melancholy duty of offering to your Royal Highness, in your bereavement, this expression of their sincere and heartfelt sympathy, and this record of their sense of the special loss which the Society has suffered by the death of him for whom the whole nation is now mourning.

Sealed with the Seal of the Society for the Encouragement of Arts, Manufactures, and Commerce, this Eighteenth day of January, 1892, in the presence of (L.S)

Richard E. Webster,
Chairman of Council.

Henry Trueman Wood,
Secretary to the Society.

MUSICAL EXAMINATIONS.

Sir John Stainer has been appointed Examiner in Music to the Society, and Mr. W. G. M'Naught Assistant Examiner.

ORDINARY MEETING.

In consequence of the funeral of H.R.H. the Duke of Clarence, a Vice-President of the Society, the meeting announced for Wednesday, 20th inst., was not held.

The paper by Prof. Lewes, set down for that meeting, will be taken at the meeting on March 2nd.

Chicago Exhibition, 1893.

A meeting of the Royal Commission was held on Monday, 18th inst. Present:—The Attorney-General, M.P., in the chair; W. Anderson, D.C.L., F.R.S., Sir Frederick Abel, K.C.B., D.C.L., F.R.S., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Sir Edward Birkbeck, Bart., M.P., Sir Frederick Bramwell, Bart., D.C.L., F.R.S., Michael Carteighe, Lord Alfred S. Churchill, B. Francis Cobb, Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., C.I.E., Prof. James Dewar, M.A., F.R.S., Major-General J. F. D. Donnelly, C.B., James Dredge, Francis Elgar, LL.D., Sir Douglas Galton, K.C.B., D.C.L., F.R.S., C. Malcolm Kennedy, C.B., John Biddulph Martin, W. H. Preece, F.R.S., Sir Owen Roberts, M.A., F.S.A., Prof. W. C. Roberts-Austen, C.B., F.R.S., Sir Saul Samuel, K.C.M.G., C.B., with Sir Henry Trueman Wood, as Secretary.

METALLURGICAL COLLECTION.

The Royal Commission for the Chicago Exhibition are endeavouring to form a typical collection illustrating British Metallurgy for the British Section, and they are now applying to Owners and Managers of Metallurgical Works asking for specimens of each of the principal metallurgical products produced at the works, and also for specimens illustrating various processes.

Dr. E. J. Ball, the Instructor in Assaying at the Royal College of Science, South Kensington, has kindly undertaken to classify and arrange the Collection, and specimens may be addressed to him.

Specimens of special value or rarity are not expected, but samples are desired of Metals,

Regulus, Slags, Alloys, &c., so that the Collection when complete may be fully illustrative of the condition of metallurgy in the kingdom. Samples of metal sent should, where possible, be freshly fractured, and attention should be paid to any special unmanufactured products for which a market is desired.

At the close of the Exhibition the Collection will be presented to an American museum, so that it will have a permanent value.

Proceedings of the Society.

FOREIGN & COLONIAL SECTION.

Tuesday, January 12, 1892; Sir THOMAS WADE, G.C.M.G., K.C.B., in the chair.

The paper read was—

THE LAOS STATES, UPPER SIAM.

By ERNEST SATOW, C.M.G.

The northern and eastern portions of the dominions which acknowledge the sway of the Siamese king are known to geographers as the Laos, from the Siamese name of their inhabitants. Along the banks of the Mĕkhong, or Cambodia River, these populations, though governed by officials of their own race, are directly subject to Bangkok, but in the north they are divided into six States, ruled over by their hereditary chiefs, and thus are semi-independent. These six States are Chiengmai, Lamphun, Lakhon, Nan, Phrĕ and Luang Phrabang. In the first five, Asiatic subjects of the Queen, chiefly natives of Burma, have for many years carried on an extensive trade in teak timber, taking leases of the forests from the chiefs and other owners. Almost from the very commencement of the diplomatic relations with Siam, which followed upon the conclusion in 1855 of Sir John Bowring's treaty of commerce, disputes and lawsuits began to arise in onnection with the rights thus obtained. In 1874, a treaty was negociated between the two kings of Siam and the Viceroy of India, which had for its principal object the establishment on the spot of tribunals for the determination of such disputes, but having failed in completely securing the objects aimed at, it was superseded in 1883 by a fresh treaty concluded between Great Britain and Siam. Under the new treaty a native court was created at Chiengmai for all cases, both civil and criminal, in which British subjects were either plaintiffs or defendants, and a Vice-Consul was appointed to reside there, to watch over the execution of its provisions and to protect the interests of her Majesty's subjects. The Judges of the Court were Siamese, and a Commissioner was in addition appointed by the King of Siam to discharge functions similar to those of the British Resident at a native court in India. At first the treaty applied only to Chiengmai, Lamphun, and Lakhon, but its operation was afterwards extended to Nan and Phrĕ. The arrangements looked well on paper, but owing to the vast amount of arrears which had accumulated in consequence of the failure of the Treaty of 1874, they did not work smoothly; so that it became advisable for me to pay a visit to Chiengmai, in order to make myself acquainted with the causes which impeded the settlement of the outstanding claims, and to gain personal insight into the circumstances and condition of the teak trade. Having obtained the sanction of her Majesty's Secretary of State for Foreign Affairs, I started on my journey towards the end of 1885, and spent nearly three months in travelling through regions which have seldom been traversed by Europeans, and still more seldom described.

The usual route to Chiengmai is up the western tributary of the Menam to Rahĕng, and thence by elephant through Lakhon, or by boat up the rapids. But I had been told, on what seemed to be excellent authority, that the voyage up the eastern branch to Utaradit, and thence by land through Phrĕ, Lakhon, and Lamphun, was really much shorter, which doubtless is true when there is plenty of water in the river and if one travels through without stopping. This year, however, the water had fallen below its usual level, or rather had never attained it during the rainy season, so that the launch could not get so far as Utaradit, and for the latter portion of the way we had to pole our heavy boat against the current.

Within a few hours after my arrival I received a visit from the King's Chief Commissioner, Phya Monkri by name, a man of about forty, strongly built, and with a pleasing countenance. During my stay, which lasted a whole month, I had frequently occasion to see him on business, but of that I shall say nothing in this journal. He goodnaturedly offered to do anything in his power to render my sojourn agreeable, and afterwards fulfilled his promise in a way that proved his words to be more than a mere compliment. Of this official I shall always retain a most agreeable memory.

On the following morning a son of the Chief

and one of his nephews, the latter an extremely intelligent young fellow, named Chao Landokmai, came to call, and after they were gone I went to return the Chief Commissioner's visit at his official residence, a large native building not far from the Vice-Consulate. Here I made the acquaintance of Phra Uphai, the principal judge of the Court established by the Treaty of 1883 for trying cases between British subjects and those of the King of Siam, among whom the Laos are naturally included. He turned out afterwards to be a very amusing fellow, full of legal stories, and I regretted very much to be unable to converse with him in his own language. In the afternoon I called on Dr. McGilvary and Mr. Martin, two American missionaries, the former of whom has been established here a long time, and on Dr. Cheek, who, originally a medical missionary, has now gone into the timber business. He speaks Lao like a native, and is a very cultivated man into the bargain. I took a great liking to him, which was increased by a four days' tour we took together among the mountains, and we ultimately made the journey down the Mĕ Ping to Bangkok in company.

I had now only to make the Chief's acquaintance, which I did on the following afternoon. He lives in a fine house built in semi-European style, and is a jolly-looking old fellow of sixty-seven, not without a certain measure of native cunning, but intensely ignorant. The furniture was European, and on the floor were spread a number of gaudy Brussels carpets. The conversation turned upon the obstruction to navigation caused by the rapids in the river on the southern boundary of his territory. He would not believe that dynamite could be used to destroy rocks. Small boulders could be removed, but the bigger ones—never. There is no doubt that he looks upon the rapids as a heaven-bestowed barrier against aggression from the South, and it is certain that but for their existence the independence of the three Lao States would long ago have become a mere tradition. But some day a railway may be constructed up the Mĕnam valley, and then we shall witness the complete incorporation of Chiengmai with Siam.

On the next day he returned my call at the Vice-Consulate, arriving there in a sort of shabby victoria drawn by one pony. This is one of the two carriages that Chiengmai boasts of, and it is in constant use for official visits. On this occasion I puzzled the Chief very much by asking the name of a tree we have in the Legation grounds at Bangkok, which tradition says was brought from Chiengmai by Sir Robert Schomburgk about twenty-five years ago. I described through the interpreter the flower and leaf, but he would not recognise it, and at last became quite angry at being asked what he evidently thought was a most foolish question. "Why," said he, "all trees have flowers; how should I know." Then we got upon the subject of orchids, which seemed to interest him very much more. There are perhaps a hundred and fifty species found in the Chiengmai woods, and the women are very fond of wearing them as ornaments for their hair; the same practice is common in Burmah. Many of the better-known species have their distinctive native names. There is one which is brought every year from Muang Yuom by the Lawas who inhabit the mountains, and presented to the Chief as tribute. It has an insignificant greenish white flower, but is much esteemed for its fine odour, which the Chief asserted could be recognised in the city while the tribute-bearers were still several miles off. But the specimens I saw had a very faint scent. I asked him what there was in his dominions particularly worth visiting. Well, there was an ancient temple at a place called Chom-tong, distant about two days journey on elephants, that I ought certainly to see. I could take it on my way down to Bangkok. Then there were some hot springs at the village of Ban Punkum, near Doi Saket, some distance to the north-east. Until within a few years ago the water used to leap into the air with a loud noise. Then I ought to visit the pagoda halfway up Doi Su-thĕp. I asked him about Doi Chieng-dao. Well, the people used formerly to ascend it, but it is now inaccessible. He did not know why, but the Laos could not go up any longer. The *Phi* (spirits) would prevent them.

Of all unlikely places in the world where an evening suit could be needed, I had thought Chiengmai was one of the most improbable. Great was my horror, then, when I received a formal invitation to dine with Phya Monkri, and learnt that as the Chief would be there, a tail-coat was expected of me. Luckily, I had a black morning coat amongst my baggage, and my host was induced to accept it as a substitute for the garment prescribed by our etiquette. He has a pleasant private residence in the city, built of teak, and surrounded by a pretty garden. The drawing-room and dining-room were completely furnished in simple European style, and the dinner was provided

by a Chinese cook. One of the best dishes was Siamese curry, which I prefer to all others that I have tasted. The predominant flavour is derived from lime peel, and it is very pungent, owing to the free use of chilies, but there is nothing in the world that comes up to it, not even the prawn curry of Ceylon. Phya Monkri is a man of taste, and his verandah was hung round with ferns and orchids. He is fond of bric-a-brac, and had already collected some fine Buddhist bronze statuettes, several of which were extremely ancient. His spittoons of silver repoussé work, eighteen or twenty inches in height, were magnificent, and cigars were handed round in a gold box such as the Chinese workmen of Canton are famous for.

The city of Chiengmai covers a considerable area, and consists of two portions, the original city being square, enclosed by a high wall and a moat, round two sides of which a more modern extension has been added.

By far the most remarkable sight which Chiengmai affords is the early morning market. To this between two and three thousand women flock in every day from the surrounding country, each bringing her small supply of goods for sale, and coming in some cases from long distances, even as far as from Lamphun itself. They line both sides of the road leading up to the outer western gate, the first part of the main street to the second gate, and from the cross roads in the centre of the city they spread right and left for a long distance. Their wares are laid out on mats spread on the ground, behind which they squat in little groups of twos and threes. No shouting or loud-voiced chaffering over sales, as is the case with the Siamese market women in Bangkok. The stock-in-trade of a group seems to be of no great value; a few half-dried chilies, some bundles of cut tobacco, three or four pieces of petticoat cloth, a pile of buffalo-hide wafers sprinkled with sesame seed, or a few pounds of pork, would furnish out half-a-dozen of them. It is seldom that you see either fish or rice exposed for sale, and I have no idea where the people who deal in these principal articles of food are to be found. The only shops in the town are small booths, which line the street between the first and second gates, and here you may buy English cotton goods, yarns, and lacquered boxes from Burmah. In the cross street outside, which runs northwards and parallel to the river, you can procure a few vegetables and miscellaneous European goods from Chinamen or their native wives. The shops inside the walls seem to be mostly in the hands of the Burmese men and women. There are two European stores outside the town, one kept by an Italian, the other by a German, the latter having his place of business on the left bank of the river. Rupees are the universal currency. The city is laid out on the same principle as Phrĕ, Lakhon, and Lamphun. You can hardly see the houses for the trees. Each dwelling stands in its own garden of fruit trees, including a fair proportion of areca palms. A Lao city is like an assemblage of rural suburbs turned outside-in, and intersected by green lanes. The best theory is that the walls are intended solely as a refuge for the population of the province in time of war, and not as its usual place of habitation. The Chief's palace is naturally inside, as are also the houses of his numerous relatives, many, if not most, of whom occupy official posts. Artisans of merit have no freedom. As soon as a man becomes noted for skill in silver *repoussé* work or the manufacture of lacquered boxes, he is overwhelmed with commands from the Chief and his relations, who pay little or nothing for the labour they thus monopolise. Consequently, anything like a healthy development of the natural artistic capacity of the people is not to be expected, and there are no shops where you can buy their productions. You must supply a silversmith with rupees, and wait your turn until he can find time to work the silver up into the cup or basin you require.

One morning I went out riding with Phya Monkri, to visit an old temple in the centre of the town, and to inspect the process of lacquering. The Wat Phra Sing stands almost in the centre of the town, in a line with the eastern and western gates. The story goes that the principal image here enshrined was being carried, soon after its completion, across the town to be deposited in a temple that had been built to receive it on the opposite side, but on reaching this spot apparently declined to proceed any further. No efforts of the porters were sufficient to move it a single inch beyond. They left it for the night, and next morning it was found with its face towards the street by which it had come. This was looked upon as an interposition of the Buddha himself, and no further attempt was made to resist his will. A temple was consequently built over the image, and the main street was deflected so as to pass round it. There are signs that laterite was largely employed in the original construction. On entering the enclosure, the gateway of which is obstructed, as is usual in the Lao

States, by a solid log supported on two posts (something like the wooden horse of a gymnasium), you see before you a low wooden building, the gable of which, fronting towards the entrance, is decorated with tinsel. Its uprights and cross-beams are much out of line. It has the usual arrangement of several graduated roofs succeeding each other along its length, but the sides are enclosed by walls pierced for windows, which is not general. The doorway is guarded by two five-headed nagas in chunam. The pillars which support the roof are decorated with tinsel and stucco mouldings. This building is said to have been at one period the audience-hall of a chief; if so, it would seem to be a reasonable supposition that in earlier times the architecture of temples was the same as that of palaces. I was told that formerly it was the custom, on the death of a chief, to present his house to a temple. No doubt it had to be removed and re-erected in the temple grounds, otherwise the priests would, in the course of ages, have come to possess all the land in the city. Under the caves were some excellent carved triangular wooden brackets, the upper part of which was occupied by one, two, or three nagas, the involution of the serpents being cleverly managed, while the lower part was filled in with open work carving having a conventional design. This building is the *wihan*. Behind and at right angles to it stands a chapel containing an elaborately modelled brick and chunam shrine open on its four sides, having a sitting Buddha in the centre. The interior walls are decorated with paintings in monochrome, depicting scenes in heaven and hell.

The third chapel, in which is enshrined the Phra Sing, has been but recently restored. Its exterior is decorated with heavily gilded carvings, while the interior walls are covered with paintings on plaster, representing a variety of lively scenes, both architectural and landscape. The precious image whose obstinacy led to the foundation of this temple, is contained in a solid *dagoba*-like vaulted brick building in close connection with the chapel. This is entered from what is usually the seat of the Buddha's effigy in other sacred buildings, and is closed by an iron door. The walls and ceilings are thickly covered with gold leaf, as is also the image itself, which represents the Founder, sitting cross-legged with the left arm folded across the lap, while the right hand hangs over the knee. The countenance is more characteristic and individual than is usually the case with Buddhist images in Siam. On the base is an inscription in incised characters of the early type, found at several other temples in Northern Siam, rendered almost indecipherable by the excess of gilding. The image, which is between three and four feet in height, reposes on a square pedestal of stuccoed brick, painted black. Its age was said to be about three centuries, but, in the absence of any trustworthy chronology amongst these people, it might be of any period previous to the resettlement of Chiengmai by the Lakhon princes. The superior type of face, however, is in itself an argument in favour of a considerable antiquity. Close by this chapel stands a ruined *phra-chedi*, the base of which is surrounded by figures of elephants, presenting the front towards the spectator, in style similar to one which exists at Sawankhalôk. To the right of the *wihan*, just described, is the *hô-tam*, or library of sacred books, a small but comparatively lofty building, to which access is obtained by two flights of steps. Its lower story is adorned with lifesize chunam figures of *Thepha-phanom*, or angels.

We also visited the residence of the late Uparat, or heir-apparent. Part of the buildings have been pulled down since his death, but the principal one still remains. It is the largest house in Chiengmai, probably not even excepting the palace of the Chief. Bands of carving in geometrical patterns run round both exterior and interior. The beams and side brackets are all carved. Gigantic pillars of teak wood, smoothed with the native knife-sword, support the roof of the audience-hall, and here, as elsewhere, the use of saw and plane seems to have been unknown at the date of its erection. At the further end of the hall, on feet modelled as elephants and tigers, stands a handsome wooden screen; its front has a peacock in low relief facing towards us with its tail spread, while other animals, as dogs and tigers, very small in proportion, play about its feet. Behind the screen is a doorway, affording access to the other portion of the building, which is entirely without windows. At the near end of it stands a huge wooden cupboard several feet higher than the floor, which formed the state bedroom of the Uparat; being entirely covered in with planks, there was no provision for the admission of air or light. Its occupant must have felt it possible to sleep securely and soundly. This is said to be the normal style of construction for

Lao bedrooms. The eaves of the roof, which come down very low and render the interior extremely obscure, are supported by wooden brackets, carved in the form of the fabulous bird *Krut*, the Indian Garuda.

We rode along the southern street through the market, where women were engaged in cutting up and selling the carcases of pigs, and out by the Chiengmai Gate to a village occupied by Chieng-tung Shans, engaged in the lacquer manufacture. These people, or their forefathers, were taken prisoners in war, and in accordance with the custom of Indo-China were forced to migrate into the dominions of their conquerors. Men, not territory, are the prize of successful warfare in these countries. In appearance, costume and language, they do not differ from the Laos, but their accent is said to be unlike that of the Lao inhabitants of Chiengmai.

The form of the lacquered articles produced by these people is either cylindrical or cup shaped. The core is of fine bamboo basket-work, coated with lac, or with lac mixed with the ashes of straw. When the lac is dry, the basket is turned on a very simple lathe, the wheel of which revolves backwards and forwards, the principle of the crank being apparently unknown. In place of the more scientific appliance, the workman uses a treadle, which turns the wheel one way, and it is brought back in the opposite direction by a long bamboo which acts as a spring. The tool employed for smoothing is a bent chisel, sharpened at the end and sides of the bend. After the process of shaving has once been performed, fresh lac is applied, and it is shaved again; for the finest work this is repeated as many as twenty times. After being turned, the surface is polished with a piece of fine grained reddish stone of a sandy texture. The natural colour of the lac when dried is black. After the coating has reached a sufficient thickness, the required design is drawn on it by means of an ordinary double-ended tool, and lac, coloured red with vermilion, is rubbed into the pattern thus obtained. Finally, the completed article is polished by covering it with a mixture of lac and vegetable oil; the polish is simply smeared over with the finger and left to dry. The drying takes place on a shelf closed by a curtain, and the vapour of water is not, as in Japan, considered necessary. The lac is obtained from a tree which is certainly not the *Rhus vernicifera*, and I am inclined to believe that the process and the materials employed do not differ from those used in the similar manufacture which is carried on in Burmah. For my own part, I consider the Burmese article to be superior to what is produced in Chiengmai. One of the workmen who was engaged on a cylindrical box about 8 inches diameter and 3½ inches high, said that he would receive a rupee and a half for his labour, but that the completed article would fetch ten rupees in the bazaar. The designs are drawn from memory, and consist mainly of conventional flowers and leafage, with sometimes a bird introduced, the peacock appearing to be a favourite.

I am sorry that I could not find time to visit the silversmiths who live in the same part of the city. Their work is of two sorts, incised and *repoussé*. The latter is said to be produced by hammering on the outside of a thin sheet of metal formed into the required shape, and filled with resin, and the pattern is thus brought out by a process of indentation. But it will be better not to accept this, without reservation, as a correct account.

On the 15th of January I dined with the Chief, who had courteously allowed me to fix the hour; I chose seven o'clock, but as the word had previously been passed to the cook to have everything ready by six, we found all the dishes cold when we sat down, except the soup and Siamese curry. The other guests were Mr. Gould and Mr. Archer, of H.M. Consular Service, the Siamese Commissioner and Luang Suriya, the Judge of the International Court, and some younger members of the Chief's family. We sat on chairs at a long table, arranged in the European style, and were provided with knives and forks. The natives eat with their fingers as a general rule, but this was a special occasion. Fried wafers of cow and of buffalo hide were served with a sauce composed of fermented tea leaves, pork fat, onions, and a fourth ingredient which I do not recollect. A pile of these wafers was placed between the Chief and myself, and we dipped by turns into the same sauce-bowl. He was evidently pleased to find that I could eat them. You can offer no more delicate flattery to an Oriental than to partake of his native food. Though rather greasy, these preparations of skin were not unpalatable, especially a spongy variety which was well toasted. The conversation was heavy, until someone started the subject of Burma, and the Chief's eyes glittered with delight as he called to mind how his people had pursued a Burmese pretender, who appeared in Chiengmai some years ago, and killed one or two of the impostor's

followers. The old man would not believe that the British forces had taken Mandalay; the whole story was too incredible. As if any European could have conquered the great kingdom of Burma, which had been too much for the Laos themselves a hundred years ago, with so little difficulty. Moreover, our own Burmese subjects in Chiengmai disbelieved the rumour. It had been invented in Chiengmai itself by the foreigner who sat in a hut at the end of a wire and pretended to be in communication with Bangkok. Everyone knew that it was impossible. After dinner we admired his collection of gold boxes and basins of *repoussé* work, kept in a series of glazed cupboards at the back of the room, many of them very large and heavy, and probably ancient. They are the handsomest things of the kind I have seen in Siam, and the intrinsic value of the mere metal must be several thousand pounds. His crown, a gift from the King of Siam, was also produced. It is a pyramidal arrangement, like that of the king, only wanting (I was told) certain feathers, and is covered with small rubies and other precious stones.

Another day I rode out with the Chief Commissioner to the woods at the base of Doi Suthĕp, in search of orchids. Passing through the town, we issued from the Patu Suen-dok on its western side. This gate is named after a pleasure garden of the Chief of Chiengmai, situated about a mile from the walls, which has been allowed to run to waste. As we emerged from the gate, the great mountain, which had hitherto been concealed by trees, appeared close at hand, almost overhanging our heads. The road leads in the direction of a pagoda built half way up the mountain side, and is broad and grassy as far as a small *salâ*, where we branched away to the right across the now dry terraced rice-fields. At the edge of the woods we were met by a hale old man, who is the "governor" of the mountain, accompanied by four or five men carrying baskets to hold the plants we expected to collect. The path ascended over the sparsely wooded spurs, and wound along to a beautifully cool and romantic spot on the banks of a torrent called Huei Mĕ-chang-khien. Here we found a white clematis, *doh niŭ*. Our luck was pretty good, and we succeeded in obtaining a dozen or more varieties of orchids, which seem to prefer trees that are more or less decrepit and decayed. One of these has a pretty white flower, touched with mauve and pink, and giving forth a pleasant fragrance. It is not much admired by the Laos, who have given it the name *dok-üang ki mâ*, which, in English, has such a malodorous sound, that I will leave it untranslated. On our way back we crossed the fields in a different direction, to the north-west angle of the city, and then along the north wall to the river side wall. Some of the fields were being broken up for a winter crop of rice.

One morning we received a summons to the Chief's house to be present at the presentation of the tribute orchids already mentioned. The ceremony took place in the audience-hall. We all sat on chairs, ranged in a semicircle, the Chief wearing his everyday dress. The Lawas from Mu'ang Yoom were introduced by an old Lao, who has served under seven successive chiefs of Chiengmai. They brought with them a tazza full of amaranths, which this old man handed to the Chief, repeating first a long exorcism, during which the Chief held up his hands, as if in prayer. Next, a long joint of bamboo, full of arrow poison, and a few skeins of cotton yarn were offered to him. Then a small stone mortar, full of powdered ginger, was handed to the Chief, who put some in his mouth, chewed it, and spat it out, to symbolise the fertilisation of the ground for the reception f the rice seed. The orchids were there, stuck into two sections of a tree, but apparently no reference was made to them. The whole business was got over very quickly, and was of the simplest possible character. I should mention that, at the end, the Chief lifted up his voice, and delivered himself of a short oration, of which I cannot give the contents, as no one thought it worth translating; but what impressed me most was the informal and "fine-old-English-gentleman, all-of-the-olden-style" manner he assumed. The Chief stuck an orchid through the hole in his left ear lobe, and gave us each a sprig to do likewise, but not being provided with those useful apertures, we had to put them behind our ears, which is, after all, quite as elegant as the native manner of wearing a flower. We then adjourned to a raised shed, to hear some music performed by women on a sort of three-stringed lute, having three frets, which was placed on the floor in front of the player. An ivory pencil is used for striking the strings. The performers were two women, who played in unison, and the music was of simple monotonous character. There were a number of bamboo harmonicons and sets of small gongs lying about the room, which seemed to be of Burmese origin. The native Lao instrument is the bamboo flageolet.

During the whole of my stay in Chiengmai, I constantly longed to ascend Doi Suthĕp, and ascertain its height, but business at first, and afterwards an unseasonable period of three days persistent rain, frustrated my hopes. I managed, however, to get as far as the pagoda, which is approximately 2,200 feet above the city. Leaving the Vice-Consulate one day about a quarter-past nine, I walked my pony through the city, and out by the Patu Suen-dok, reaching the deserted garden by ten. This place is supposed by some of the foreign residents to be the site of an earlier town. But it is much smaller, by ten or twelve times, than the present city, and if it were ever surrounded by a wall, nothing now remains but an earthen mound. Immediately opposite, on the south side of the road, are the remains of a Buddhist temple, standing in a square enclosure, pierced on the north, south, and east sides by arched pyramidal gateways, nineteen feet thick. Inside of this is a smaller enclosure, at the west end of which rises a lofty circular *phra-chedi* on a square base, having a smaller *phra-chedi* at each corner, and a steep flight of laterite steps on each side, at the top of which is an arched gateway. These eight structures on the outer edge of the base have sharp pyramidal pinnacles, while the coping of each flight of steps is formed by a five-headed *naga*. The *wihan*, which fronts towards the east, has four graduated roofs, the highest end being next the *phra-chedi*, its interior consisting of a nave and two aisles. At the west end is a colossal sitting Buddha, some twenty-four feet high, of brick and mortar, freshly gilt. Back to back with the *wihan* stands a small but massively constructed shrine, decorated with stucco ornaments, and containing a small sitting Buddha, apparently quite new. The doorway of this shrine is curious, being a mere longitudinal slit, as it were, in the wall of the building; or, rather, it looks as if the wall, with all its mouldings and other ornamentations, had been divided vertically in the centre and then pulled apart to show the image in the interior. Gateways on this principle, which look as if a small *phra-chedi* had been cut in two, and its parts set up on either side of the passage-way, are, however, not unfrequent.

Between the city and this garden are dotted here and there several tall *phra-chedi*, of which scarcely anything now remains but their brickwork core. Nothing, however, can be inferred as to their having been included within the walls of an earlier city.

A quarter of an hour's ride beyond the *salá*, where we had diverged from the road on a previous occasion, brought me to the foot of the mountain. Here I left the ponies, as the path was too rough for them, and began to ascend the foothills, which are covered with scrubby trees, now almost denuded of their foliage. Further on the path divided, on the right ascending a sunburnt, clayey spur, through sparse forest; the left, following a purling stream through densely-growing umbrageous trees, and over damp, black soil. This contrast would seem to suggest that it is want of moisture, and not cold, that causes most of the trees in the Laos to shed their leaves during the winter. Close to this spot a delicate dwarf bamboo, having stems no thicker than ordinary grass, and reaching a height of about two feet, was pretty abundant. At a height of about 2,100 feet above the sea, acorns were lying in the pathway. They had fallen from large trees with lanceolate leaves of rather thin texture. There was also what I took at first to be the fruit of an oak, but may, perhaps, have been a diminutive chestnut; it was covered with prickles, and most specimens had only one kernel. The shell split naturally into three parts. It is certain, however, to judge from acorns which were afterwards shown to me in Chiengmai, that there are five, if not six, distinct species of oak on Doi Suthĕp. Ten minutes below the summit was a green swampy glade, where a party of men and women were gathering the flower *dok un*, which the latter wear in their hair. To represent the pronunciation of the second syllable to the eye, it should be printed half a letter higher than the first. Such a system of noting the tones of these monosyllabic languages would, if practicable, be far more effectual than the use of accents or other diacritical marks, which are so easy to forget. For in Lao, as well as in Siamese, it makes all the difference in the world whether you pronounce a syllable with a rising or falling inflection of the voice, with a combination of both, or with no inflection at all.

The pagoda stands at the top of a detached knoll, and is approached by a long flight of steps at the back, on either side of which stands a row of lofty pines, evidently planted there, for although the tree can be seen in abundance on the summit of the mountain, there are none growing in the woods which surround this knoll. The leaves are three in a sheath, and the cone is from 2½ to 3 inches long. It is possibly the *Pinus* known in

Burma. On the slopes, *Pardanthus sinensis*, an irid sometimes met with in the neighbourhood of certain mountains in Japan about 1,000 feet above the sea, is common enough.

At 12 o'clock I reached the temple, which stands 3,600 feet above the sea, and 2,200 feet above Chiengmai, according to my calculations. On the south side of the hill there were bushes of a large white bauhinia, which sent forth a delicious fragrance. The plain was almost enveloped in mist at this hour, so that the mountains on its further side were indistinguishable. Down below, the thermometer was probably 85°, while at this elevation it marked only 72°. I sat patiently waiting for my luncheon to arrive, and enjoying the fresh air till a quarter to two, when the pangs of hunger began at last to make themselves felt, and, as there were no signs of the basket's approach, I resolved on descending in search of it. About halfway down I met one of my men slowly toiling up the steep path, and no doubt he would have explained the delay to his own satisfaction, at least, if I could have understood what he said. But all I could make out was, that somebody else was to blame. Just below was the junction of the two paths, so I hastened down, and enjoyed my meal in the cool shade, while the servants hunted for orchids. From this spot it took me half an hour more to the places where the ponies were waiting, and I got back to Chiengmai about the hour that it was expected I should have reached the pagoda.

On the 21st January, after many pros and cons as to the best excursion to be made in the neighbourhood, I started to make the circuit of Doi Suthĕp, if it should be found feasible, with elephants. Dr. Cheek, of the American Mission, the Rev. Mr. Webster, who is a missionary to the Karens, and belongs to the Mission in Burma, and Mr. Archer were my companions. We started on ponies, the baggage being carried on nine or ten elephants, including a few spare ones for riding on in case it should turn out impossible to take the ponies across the ridge at the back of the mountain. Leaving the Patu Suendok about eleven, we struck at once into a track leading across the parched rice fields to the south-west, and in about half an hour's time reached the village of Phông Noi, on a streamlet called the Huei Sai. Beyond this, we crossed undulating stony ground, covered with thin forest, and came down upon the Huei Mĕ-hia. Across the stream rises precipitously a pretty wooded hill, named Doi Kham, on which the sun shone brilliantly, lighting up the scarlet tints of the dead foliage. Following this stream for some distance, we at last began to ascend a long horizontal spur, that runs out from Doi Suthĕp in a southerly direction, descending on the other side to Ban Phông, on the right bank of the Mĕ Thachang, a swiftly flowing rivulet several yards wide and about a foot deep. Siamese and Laos are alike averse from long journeys, and the Chief's people, in conjunction with the king's Commissioner, when settling the itinerary, had fixed upon this place for our first encampment; but as it was only one o'clock when we got to Ban Phông, the more active Western blood rebelled against the arrangement, and we determined to go on a bit further after having our lunch. Besides, the *wat* which was destined for my accommodation was by no means a comfortable building to pass the night in. I forgot to mention that the Chief had lent me his best elephant to ride, besides several others, and had, moreover, sent with me a *Chao*, or prince, to act as chief of the escort, and make things generally comfortable. Dr. Cheek had four of his own elephants, if not more, and we should have made an imposing cavalcade altogether, but for the dislike of the elephant for his cousin the horse, which forced us to travel in two separate bodies. There were, of course, a crowd of followers on foot, besides the cook, servants, grooms, and mahouts.

We left again at half-past three, and followed the bed of the stream for about a mile through a shaded rocky gorge, fording it pretty frequently until we emerged into a flat-bottomed little valley cut up into terraced rice-fields. The scenery here is soft and friendly, and recalls many a bit of Japan; on every side rose steep knolls covered with trees, whose brilliantly red foliage was lighted up by the sun now sinking in the West.

Keeping slightly away to the right, in full view of the long ridge which extends westwards from Doi Suthĕp, we climbed a steep hill, which we supposed to be a spur dividing the side valleys of the great mountain, but, to our great surprise, came down again on the same stream, to ascend once more to the top of a still higher hill on its right bank. Crossing this, we descended once more, and, passing through a tract of forest, found ourselves, at five o'clock, still on the right bank of the stream, where we waited for the ponies to convey us across the muddy ford. The general character of the country hereabouts is that of open cultivated valleys divided from each other

by constrictions of the hills through which the stream has cut its way. After another half-hour's ride, the valley opened out into a huge amphitheatre, with rice-fields rising one above the other, like broad rows of seats, in the centre of which stands the hamlet of Mu'ang Ha. We got here at half-past five, and found the *wihan* of a little *wat* prepared for the occupation of Mr. Archer and myself. Dr. Cheek and Mr. Webster, the latter of whom now caught us up after having been behind all day, pitched their tents on the opposite side of the stream.

Howdahs were taken off, and the elephants turned out to feed, while the natives lighted fires all round to cook their rice and to lie by during the night. I imagine that they mostly slept in the open air, wrapped up in their cotton blankets, and at this season of the year there was probably no danger in their lying on the ground. Height above the sea 1,660 feet. The southern summit of Doi Suthĕp bore E.N.E., so that we had already performed more than a quarter of the circumference, since from the Vice-Consulate it bears W.N.W.½W.

On January 22nd the thermometer at half-past six indicated 56°. We started on foot at half-past eight, and traversing the terraced rice fields quitted the valley at its further end. After crossing a steep hill covered with forest, we again descended to the stream which we had followed all the previous afternoon, and after crossing and re-crossing several times finally left it behind us. Its source is evidently somewhere on the southern flank of Doi Suthĕp. We now climbed a steep ascent over stiff red clay to the top of a knoll, called Doi Nyung, which we reached at twenty past nine. From the rising ground to the right of the path we took bearings of the principal points. The southern summit of Doi Suthĕp bore nearly due east, while the *wat* where we had passed the night lay to the south-east. Beyond it we could see a portion of the Chiengmai plain and of the range of mountains which borders its eastern side. The northern summit of Doi Suthĕp bore east by north. A long pine-clad ridge running towards our left was seen extending like the sharp back of some emaciated animal, from a point about 600 feet below the summit. So clear was the atmosphere that with the naked eye we could easily distinguish the form which is distinctive of the coniferous order. The altitude of this spot was approximately 2,000 feet. It would, perhaps, not be impossible to reach the nearer summit of Doi Suthĕp from here in one day, but the ascent would be long and toilsome, as there is no path, and finding one's way up a mountain side by the mere aid of the compass is no easy task.

We waited for the elephants and ponies to overtake us, and continued our journey at half-past ten. The path lay through undulating forest for three-quarters of an hour, till we reached a small open space that seemed conveniently situated for luncheon. On our right were the spurs which stretch down north-westwards from the mountain, while to our left the country seemed to consist of hills and valleys extending in the direction of a plain that was, however, invisible, and perhaps may exist only in our imagination. We had walked a good deal faster than our baggage animals, and it was more than an hour before they came up. Then we had to lunch and smoke a cigar, so that it was one o'clock before we were again under way. By this time every one of the party had walked quite enough for one day, and we got into our howdahs, the sole merit of which, in my opinion at least, is that they make you so uncomfortable that in a short time you feel going on foot to be less fatiguing.

The track ascended first to a height of 2,150 feet, and then wound for a couple of hours round the deep ravines on the steep flank of a lesser mountain, descending rather rapidly at last to a teak forest, where a party of men were working under Dr. Cheek's Burmese contractor. Probably it would be more exact to say Peguan, but this is a distinction that is seldom observed in Siam, although it is not without its significance. The forest occupied a tract of almost level ground, and the timber that was still standing or lying about, ready to be dragged, was consequently not of first-rate quality. Leaving this valley, we crossed a low ridge, and a few minutes after four o'clock reached the hamlet of Ban Samöng, where we put up, as usual, at the *wat*, but not this time in the *wihan*, as there were some long open sheds outside that promised more light and air than the dark and unventilated church. This village, which lies at about the same altitude as Mu'ang Ha, contains eighty-seven houses, indicating a population of about 500 persons. They belong by descent to a people named Lü, that is to say, to the Shans of Chieng-tung, whence their forefathers were probably transported some few generations ago, after a successful raid made on that place by the Chiengmai Laos. They have by this time

become completely naturalised, the only difference between them and the pure Laos being in their intonation of the language.

The real object of our trip was to visit a teak forest, in order to get an idea, from actual inspection, of the manner in which the timber business is carried on. These forests exist all over the five northern Lao provinces, and many of them are worked by Asiatic British subjects, under contract with the chiefs and other owners, in some cases by lease for a period of years, in others upon annual agreements, the usual terms being a royalty of three or four rupees a log, besides the presents in the nature of a premium that are given in order to obtain a lease. The lessees seldom or hardly ever are men of capital, but obtain funds at a high rate of interest (generally 3 per cent. a month) from the Indian money lenders at Maulmein. A lessee will work part of a forest himself, another part will be sublet, and a third part will be handed over to contractors, who undertake to deliver logs at a fixed price at the bank of the stream by which they are to be floated down. The original lessee is bound to pay the royalty on each log before it leaves the limits of the forest on its way down to Maulmein or Bangkok, and to him the owner is entitled to look for payment. But sometimes he recognizes the sub-lessee by consenting to receive the royalty from him direct. The foresters, being mostly men of straw, as a rule, do not pay the royalty on taking away the timber, and in order to remove it have to give a promissory note for the amount due, with interest again at 3 per cent. a month, and they often assign by way of collateral security some indefinite number of logs still lying in the forest, or so many elephants, which are not in any way identified; this sort of document they are in the habit of styling a mortgage. Everything goes smoothly enough if rain falls annually in sufficient quantity to float out into the rivers the logs which have been dragged into the mountain stream. The forester then sells them at Maulmein or Bangkok, or, perhaps, on the way to either of those places, and having got his money is in a position to redeem the note he has given for the royalty. If he is honest he gets on all right, but many of these men have extravagant habits and prefer spending the cash on women, or temple building, the two kinds of luxury to which the Burman or Peguan is chiefly addicted. He gives fresh notes to the lessor, and the debt continues to grow at compound interest until all hope of its ever being discharged is given up by the parties. Then the owner tries to come down upon the lessee, sub-lessees, and contractors; he lays violent hands upon all the logs lying in the forest and upon all the elephants he can find, no matter whose they are, and in entire disregard of the rights of the men who have by their labour given to the timber nine-tenths of the value which it now possesses. And a pretty crop of lawsuits is the result. Another source of dispute in past times has been the practice indulged in by some of the chiefs of granting away the same forest to two different individuals, or of giving the lease of a forest to one man after he has already accorded to another the right of cutting timber, in spite of a special treaty dating so far back as 1874, by which the Siamese Government undertook to put a stop to these proceedings. In another article of the same treaty it was provided that a court should be established to try all cases between British subjects and Siamese or Laos, but it never heard or decided a single action. A fresh treaty was therefore concluded in 1883 which, as far as can at present be seen, promises to produce better results under the constant supervision of the Vice-Consul, stationed at Chiengmai to look after the interests of the numerous British subjects scattered over the Northern Lao States.

The teak from the western part of Nan, the State of Phrĕ, and from part of Lakhon, comes down the Mĕ Yom past Sawankhalôk, while a certain quantity descends from Eastern Nan and the provinces of Phichai and Phitsanulôk by the Menam Phô. A small quantity of inferior timber is obtained from the provinces of Sawankhalôk and Sukkhothai also. The two rivers unite a short way above Paknamphô, from which place the rafts pass down the Mĕnam. That of Western Lakhon, Northern and Eastern Chiengmai and Lamphun finds its way by the Mĕ Ping to Paknamphô and so to Bangkok. The Siamese provinces of Mu'ang Thön (Tern) and Rahĕng also yield a certain amount. On the west of the State of Chiengmai is the well known forest of Mu'ang Yuom, the produce of which finds its way to Maulmein by the River Salween, as does likewise that of the Thoungyeen Valley, the opposite sides of which belong respectively to Burma and to the Siamese province of Rahĕng. Further north, contributions are received from Mĕhong-son, which belongs to Chiengmai, the valley of the Mĕ Hang, and even from the banks of streams which lie in the western districts of the State of Chiengtung. A curious circumstance is the

great difference in the prices obtained at Maulmein and Bangkok. At the former port the rates for the finest logs are from 80 to 100 rupees, while at the latter they sell for no more than for 35. One explanation I heard offered is that in Maulmein there is a considerable market for shingles cut out of the "slabs" or outsides of the logs, while in Bangkok these are almost of no value, and hence the exporter cannot afford to pay as high a price for the rough logs as the teak buyers of Burma are ready to give. Logs at Chiengmai, on which the royalty of 3 to 4 rupees has been paid, are worth, say, about 15 rupees, and the average cost of transit thence to Bangkok is 8 rupees, half of which is for elephants "ounding" them over shallow places down to the rapids and thence to Rahĕng, where they are made up into rafts, the balance of the 35 rupees representing the cost for rafting to Bangkok. At Chhainat a duty has to be paid to the Siamese Government which averages another 4 rupees. So that with the high interest on the capital embarked in this trade, the profit to the forester is a very uncertain thing. If he is lucky in getting his timber out quickly, he will make money, but if a succession of dry seasons intervenes he loses heavily. Three years is probably the least time in which a log can be cut and brought down. The fluctuations of the market at home, which of late years have been severe, must also be taken into account, and it is almost a matter for surprise that any man should think it worth his while to embark in such a business.

We spent the morning in visiting a teak forest about three miles up the valley. The walk thither was delightful, now alongside the clear fresh stream, now by a path over some projecting bluff, while a brilliant sky, a cool breeze, and the sight of tall pine trees fringing a hill about 300 feet above us, contributed to elate the spirits of the party. After a prolonged sojourn in a tropical country, the mere presence of vegetation which recalls more temperate climes, is in itself a source of joyousness. At last we came to a spot where some 800 massive logs, many of them over 3 feet in diameter and 35 feet in length, were lying densely packed in the narrow bed of the stream, their lower surfaces just wetted by the flowing current. Beyond this was the forest where they had been cut. Some elephants were brought round from the opposite bank where they were engaged in dragging timber, and we saw them harnessed to logs. The gear is made of twisted bark, and is of the roughest description, passing round the animals chest, and attached to the log behind by a chain passed through a hole cut at its thick end. Rough stems of young trees are placed underneath as rollers. The elephant, on being started by the mahout, moves forward during a few moments at what is a great pace for him, and then stops for an equal space to take breath, for the clumsy band across his chest impedes respiration, so that continuous effort is impossible. When urged forward again, he utters loud cries of indignation, but with a great effort soon renders obedience to the voice of his driver. In the forest of Ban Huei Samöng the teak trees are mostly near the stream, but in some parts of the Lao States the timber has to be dragged as much as ten miles, and the labour required to get it to the bank of the stream is enormously expensive. The elephant seems to do little work in proportion to his huge size; for three days he drags timber up to noon, and then has a five days rest.

The logs are felled during the rainy season, when they are less likely to be split by the fall, as the ground is then soft. One forester cuts a single log per diem, but three usually work together, and cut the same number of logs. They use a heavy long-handled axe, in preference to a saw. We saw several fine trees lying there which had been utterly ruined by splitting, for ropes are not employed to break the force of impact on the earth. The woodmen, no doubt, try to direct the fall of the tree so that it may come down clear of its neighbours, but they are not always successful, and then the trunk comes crashing down through the surrounding branches, damaging itself and sometimes seriously injuring the men who have miscalculated the effect of their blows. Before being felled, the trees are "girdled," that is to say, the bark is roughly hacked through with the axe at a height of about four feet from the ground, so that the tree dies, after which it is usually left standing for three years to dry. But sometimes the lessee has a larger number of trees "girdled" than he can cut during the term of his agreement, and they may then be left to dry for several years, which much impairs their value. A custom appears to exist of allowing the outgoing lessee to exact from his successor a rupee for each tree "girdled" and left standing. This right should not be recognised by the courts, as it leads to waste, and the price thus paid for "girdling" is far in excess of its value. There is no written law to regulate

this industry, and the judges have therefore the opportunity, by carefully considered decisions, of giving the stamp of legality to those forest customs which common sense approves, while refusing to recognise those which are detrimental to the public interest.

There are, of course, no laws or customs having the conservation of the forests for their object, and in a few years more all the timber that is worth cutting will have been exhausted. The teak tree is self-sown, and if the forests are allowed to lie fallow for twenty years or so, the business will again revive. A regulation has been proposed by which the foresters would be heavily fined for each log felled that is of less than a certain diameter, but regulations are of little use when the officials cannot be trusted to enforce them. The unpopular system of government reserves which exists in Burma would be even more difficult of application here.

On the morning of January 24th, about six o'clock, the thermometer marked 50°, an increase of 3° over the temperature of the preceding day at the same hour.

We left Ban Huei Samöng on elephants at about eight o'clock, and taking a path through the village to the right of that which leads to the teak forest we visited the previous day, were soon engaged in the narrow bed of a mountain torrent. Here for the first time I saw an elephant refuse a bank which his mahout ordered him to ascend. Although the track, steep as it was, had been passed by nearly all the other animals, mine could not be by any means be induced to take it, and I had therefore to go round by a longer but easier way. When the path at last quitted the gully we found ourselves on some steep hills, which we crossed into the valley of another small tributary of the Huei Samöng, and continuing to mount upwards, we reached, after travelling an hour and a half, a small clearing laid out in rice fields by a colony of Lü from Ban Samöng. We asked a middle-aged man when his forefathers first came to these parts, and received in answer the information that his parents had migrated from Chieng-tung into Chiengmai territory about twenty years ago, before he was born, displaying thus the utter disregard of dates which is characteristic of people who keep no records. According to his data, his age would be little more than eighteen, although he must have been at least forty-five years old. He said he knew nothing of the Lü language. The rice-fields which lay in the immediate neighbourhood of the cottages had just been prepared for sowing, and the soil seemed a rich black loam. Under a shed some of the women were engaged in weaving white cotton cloth in a loom which consisted of little more than four posts held together by a slight framework. The people here wear a sandal of thin bamboo strips plaited together, and it is worthy of notice that it is held on by a thong passing between the big toe and the next, exactly in the same manner as the foot-gear of the Japanese. I cannot help suspecting that this contrivance is of Chinese origin. The Lao name for this sandal is *kôp*. The position of this tiny isolated clearing, so far above the village, was extremely picturesque. Steep, densely-wooded hills surrounded it on every side, except at the narrow pass by which we had ascended, and seemed to shut it off from the outer world. Lower down we had passed one of the deserted clearings of the Karens. These people, who, in Siam at least, live together in small communities, have no settled villages. They constantly move about amongst the hills, and cut down the forests to plant their crops, migrating to some fresh site after a year or two, which time suffices, it would seem, to exhaust the capabilities of the soil. Height above the sea, about 1,600 feet.

After waiting here half an hour for the elephants, we proceeded on foot up a deep shaded dell, now by the side of the stream, now above it, along its bed, and crossing it frequently. I could have easily imagined myself in some remote part of the mountain districts of Japan. In forty minutes Mr. Webster and myself, who, though not entitled to claim rank as pedestrians, went better afoot than the rest of the party, had reached the last spot where water was attainable. The height here was 2,500. Another half hour's toil brought us to the summit of the pass. Just below grew at least two species of oak, and a tall lily, bearing large ripe berries. A knoll on the right seemed to invite us to climb a little further, and, in ten minutes more, we were rewarded by a magnificent view of mountains on every side, and of Doi Suthĕp, rising high above us, about E.S.E. But deep intervening densely-wooded ravines forbade any attempt to reach it. South-west, in the direction of Mu'ang Yuom, we saw the great mountain that is also visible from Chiengmai. Far away below us, almost due west, we perceived the rice fields of Ban Huei Samöng, while, through a gap on the opposite side, we could discern other fields in the Chiengmai plain, which the

guides seemed to think must lie near Ban Katsá, the hamlet we were to reach on the following day. The ridge we had attained was covered with tall pines, and a kind of dwarf palm was common on its steep, almost precipitous sides. It was just the spot for a picnic. A guide was sent back to stop the elephant which carried our lunch; and we waited there, enjoying the view, and otherwise idling the time away, till half-past one, when the beast at last appeared. This will give an idea of the slow rate at which elephants climb, as compared with a man on foot. Neither Mr. Webster nor myself were in proper training: he had only just recovered from a somewhat severe attack of malarial fever, and I had injured a knee by too much tennis. We had, however, taken only an hour and ten minutes to make the ascent which had occupied the elephant three hours.

My Japanese servant, who carried the aneroid, had unfortunately gone on, not knowing that we were on the knoll, and therefore I was unable to determine the height, but we may fairly add a thousand feet for the half hour's climbing, which would give 3,500 feet above the sea for the top of the pass.

We quitted this delightful spot at a quarter to three. The path at first winds round the top of a pine-clad spur stretching towards Doi Suthĕp, and then plunges down a declivity in a north-east direction, bringing us to the hamlet of Pong-yeng. Just at the bottom of the hill we passed a plantation of *mieng*, or Lao tea. The natives call these plantations *pa-mieng*, or tea-forest, if *pa* be rendered literally, this term causing it to be generally supposed that the *mieng* grows wild. Laos tell you that it is found growing in commixture with other trees, which are cut down, leaving the tea-tree to benefit by the additional air and sun. But this account seems doubtful. It is possible that the Laos of Chiengmai, when the country was resettled, found old tea-trees growing in this way, and cleared them from the jungle which enveloped them, but the arrangement of the trees is too regular to allow of our supposing that they were planted by the mere hand of nature. Many were twelve to fifteen feet high, with stems two-and-a-half to three inches in diameter, and they were evidently not pruned. Some were in bud or flower, and others bore the half-ripe berry. The leaf is longer and more pointed than that of the Japanese tea-plant, and the foliage is less dense, But of its being a species of tea there can be no doubt whatever. The Laos do not drink the infusion, but prepare the leaf for chewing by burying it in pits, and it is one of their indispensable luxuries. You see a man put a lump of the fermented leaves in one cheek, which he leaves there while he proceeds to chew betel or smoke a cigarette, looking for all the world as if his face were distorted by the mumps.

The village of Pong-yeng is situated in an extensive amphitheatre surrounded by hills, and having for its area a series of terraced rice-fields rising from the centre. Here three brooks unite to form the Mĕ Sa. Northwards, above the nearer hills, rises Doi Kwamlong, where a hero of local legend lies buried below a precipitous rock near the summit. He is said to have determined the site of Lamphun by shooting an arrow from the top of Doi Suthĕp, and on the spot where it fell the city was founded. He must have used a very long bow on this occasion, since the distance is about twelve miles as the crow flies. He afterwards removed his abode to a place on the west bank of the Salween and died there. His corpse was brought home to be buried either at Chiengmai or Lamphun, I forget which, but arriving at Pong-yeng, could not be got to pass the spot where it now lies, and the spot which is pointed out to you from Pong-yeng is "alive to this day to testify of it."

As usual, we put up at the village temple, and passed the evening sitting round a wood fire, smoking and drinking whiskey punch by moonlight, while the doctor, who speaks Lao like a native, entertained some of the guides and ourselves with an interchange of marvellous sporting stories of rare animals and fish bigger than whales that are believed to haunt the waters of the Mĕ Khong. The Laos take care to place the locality of these wonders as far away as their geographical knowledge permits, and if you doubt what they say, you can go there and see for yourself.

On January 25 the barometer showed the height of Pong-yeng to be about 2,000 feet above the sea, while the thermometer, at sunrise, marked the same as the previous morning, namely, 50°. We started at a quarter-past eight, and crossed the rice-fields to the point where the Mĕ Sa makes its exit through a narrow gorge. Here, in a shady spot, is a good-sized tea plantation. A little further on we were requested by the *chao* to dismount from our elephants, as we were approaching a dangerous precipice high above the left bank of the stream, where there was a possibility of

falling over. But the peril was much exaggerated, and the animals passed safely along. In fact, there was no danger at all, but if anything had happened, the *chao* would have been rendered responsible on his return to Chiengmai, and he did not like to run the risk of having his head taken off for allowing even the little finger of a "distinguished foreigner" to get scratched. It was a pleasant walk, continually descending by a rocky path, and generally in sight of the roaring torrent. We rested half-an-hour at a romantic spot where a fallen trunk formed a natural bridge, near a pool that filled us with regret at not having our towels with us. Shortly afterwards we forded the stream, which, having now descended to the level of the plain, was taking its ease under overhanging branches. Then we climbed again up a hillside, and, descending a second time, entered a teak-forest, where the direct path to Chiengmai seemed to diverge to the right among the trees. We were in no hurry to get back there, and so kept on our way to Ban Katsa. Mr. Webster and I were in advance, the others having returned to the discomfort of their howdahs. By twenty minutes to twelve we reached the edge of the cultivated plain, and lay down under a tree to wait for our companions, who came up just an hour later.

From here it was ten minutes' walk across the rice-fields to the village. Here the *chao* wanted to lodge me in the *wat*, but as there was a stream not far off, it seemed better to migrate to its banks and pitch our tents among the trees. A capital spot was found in a grove, and while we made ourselves comfortable in the shade, the Lao guides busied themselves with the construction of a bamboo bathing house out in the stream, so that we could enjoy a bath in the clear, cool, running water.

During the evening an alarm was raised in the camp by news of an elephant in "must," that was supposed to be about to make a rush upon us. When the male is in this state he is usually isolated, and the elephant in question, which belonged to the Chief, had been sent out to the neighbouring jungle to be kept quiet until the fit was over. Somehow or other he had got wind of our party, and was reported to be coming down. His mahout was not to be found. Our *chao*, who is the Chief's principal keeper of the elephants, had a double source of anxiety. If the infuriated beast were to charge the camp, one of us might be trodden under foot and killed; and it was possible that a fight would occur between the elephant and some of our animals, which would be equally productive of disaster to them. He begged earnestly that we would go back to the *wat* and place ourselves in safety within its walls. I consulted Luang Suriya, who was of the party, and found him by no means alarmed; he thought that it would be rather good fun if the elephant did make his appearance. My other companions were of the same opinion, and we united in resolving to run the risk. In the meantime a number of men crossed the stream with torches to drive the elephant back in case he should really attempt to get near our animals, while others went in search of the mahout, whom they luckily found at last. Tranquillity was therefore restored, and we congratulated ourselves in having stood firm. In such a matter a foreigner is bound almost to be guided by what a native, speaking with authority, tells him, and if the *chao* had been alone probably I should have taken his advice, but as Luang Suriya hinted pretty clearly that the *chao's* warning proceeded from the excessive caution of which an example had already been given during the morning, we were justified in disregarding it and in consulting our own inclinations.

We were now some ten or twelve miles from Chiengmai, and as ponies had been sent out by Mr. Gould to meet us, the doctor and Mr. Archer rode gaily in on the following morning. Mr. Webster, who felt his walking powers were completely restored, preferred to proceed on foot. Having hurt my side by falling over a log a couple of days before, I had to have recourse to my elephant, and, as it was a level road, and the mahout probably was willing to get home as quickly as possible, he urged the animal to its utmost speed, so that we actually covered the distance in three hours and a half. This, you will perceive, gives him a maximum rate of 2·857 or 3·428 miles an hour, according as you take the lesser or greater estimate of the distance; and he is one of the largest elephants owned by the Chief. Slow and steady should therefore be the motto of the traveller by this kind of conveyance.

My visit to Chiengmai terminated soon after this excursion. After somewhat vexatious delays, I started for Bangkok on the 10th February. With the exception of the first three days, the whole of the journey was spent on the Mĕnam River. The distance from Chiengmai to Bangkok has been accomplished in nine days; not, it is true, without risk in

descending the rapids, and travelling part of the way at least by night. But it all depends upon the depth of the water. It took me four weeks—from the 10th February to the 10th March—and as the river continues to fall until the beginning of May, the journey must frequently extend to even a longer time. The distance is about 300 miles, as the crow flies, and is probably not more than 450 miles, when a liberal allowance is made for the windings of its course.

DISCUSSION.

Mr. HOLT S. HALLETT said this paper had been of great interest to him, as it recalled to him scenes previously visited by him in the neighbourhood, although a portion of the ground covered by Mr. Satow was quite new to him. Tea was found in various places throughout the range of hills lying to the west of Chiengmai, from Rahëng, all the way up to China. As soon as he crossed the range from Burma into Siam, his mahout brought him branches of the tea plant, which he found was about 15 or 20 feet high. Unluckily, he did not take notice of the distance the plants were apart, or if they were regularly set out; but it was very interesting to hear that these tea plants on Doi Su-thëp had been regularly planted at some time or other. Similar hot springs to those mentioned by Mr. Satow were found throughout the whole of the region, at different places amongst the hills. He came across one in the bed of the River Meping, up above Chiengmai, and another one in the bed of the Melow; but wherever he went he heard of their existence; and, from the aspect of the country, it was evident that at one time it had been subject to great earth movements, and even at present earthquakes were not unknown. The people called Lu, whom Mr. Satow met with at two or three places on his journey, were inhabitants of the State of Chieng Hung, otherwise known as Kiang Hung. Through distubances at various times they had been scattered. Dr. Neis met with many of their villages in 1883, in the lower valley of the Me U. They were also found in other places between the Mekong and Chiengmai. The *repoussé* work which Mr. Satow saw in Chiengmai was carried out exactly as he had been informed: resin was put inside a plain silver cup, and it was then hammered into shape with a tool. He understood that the Lawas, who carried tribute to the Chief of Chiengmai, were under the State of Lamphun, not under Chiengmai, but that Lamphun itself was more or less under Chiengmai; and it was interesting, therefore, to learn that there was a tribute paid by the Lawas direct to Chiengmai. Chiengmai was still independent; but, since he was there, the King of Siam had been gradually endeavouring to turn it into a province. He had heard that the heavy taxation raised in Chiengmai in recent years had caused two insurrections, and that Siamese taxes were now levied there, in addition to the taxes levied by the Shan chiefs. With regard to the rate at which elephants travelled, he might say, as the result of very extensive journeys by elephant in that country, that the ordinary rate on fairly level ground was two miles an hour; but there were some especially rapid elephants which, on a good road, would walk faster than a man.

Mr. R. L. MORANT said it might interest people to know, in view of the shortcomings with regard to Government regulations, especially for forestry, to which Mr. Satow had referred, that centralisation, which was one of the great steps of progress in civilisation, was already making itself felt under the wise and enlightened Government of the present monarch of Siam, and that now the whole country was being divided into large provinces, over each of which there was a Royal Commissioner sent direct from Bangkok, with full powers given him from the Government. This arrangement of course would rapidly and surely remove many of the shortcomings referred to, as this Commissioner was specially sent to see that arrangements were made for the improvement of traffic and communication, and for smoothing over those difficult questions with regard to lawsuits which, as Mr. Satow had said, formed one of the great pleasures of the people, and at the same time one of the great obstacles to the increase of commerce. The poor elephant had come off rather badly in Mr. Satow's stories, but it must be remembered that if he was slow he could go through almost any country, in fact, through a country where few if any other animals could go, and he was, therefore, a very valuable beast of travel.

Mr. C. M. KENNEDY, C.B., desired, as a member of the Council of the Society, to express their thanks to Mr. Satow for this most interesting paper, which was a new contribution to the contents of the *Journal*. It was valuable as affording information with regard to a country little known, and papers of this kind were particularly useful when they gave trustworthy accounts of those little known regions in South-Eastern Asia. He might add a few remarks with respect to Siam. The trade is chiefly in British hands served from the colonies of Singapore and Hong Kong. The country is rich in minerals: it contains tin and gold, and likewise ruby and sapphire mines. There are no actual statistics to show the value of the trade, but that at Bangkok might be estimated at about £4,000,000 a year, and is therefore well worth cultivating, as the tariff is moderate, and there are opportunities for considerable extension. In late years good regulations have been adopted to check the sale of spirits by Chinese dealers, which was beginning to be a very serious evil in Siam. Looking to the future, it must be expected that new routes will be opened across Siam from the Malay Peninsula to the China Sea, which will open out the country, and be of use in shorten-

ing by several days the communication between Europe and the Far East. Further information respecting Siam may be found in two recent publications of the Foreign-office, viz., Nos. 771 and 938 of the series of annual reports.

The CHAIRMAN, in proposing a vote of thanks, said that Mr. Satow's chief claim to their attention was that he had represented the British Government in Siam for four years. Of the country itself, he might observe that it occupied a position of particular eminence in a category of States which was now becoming extinct—the tributaries of China. When English relations with China began, fifty years ago, China had tributary to it—beginning at its north-east corner—Corea, and at the south-west, Burmah, Siam, Annam, and Lewchew. Japan might be said to have absorbed Lewchew. Corea had passed into such a position that, although she made perhaps a nominal tender of tribute, her old relation to China was either annihilated, or about to be. Burmah had been absorbed by England, Annam by the French, to all intents and purposes. Siam, which was let alone by the foreign powers, took the almost unexampled step of deliberately withdrawing, little State as she was as compared to China, from her position of tributary, and had, within the last fifteen years, formally signified to China that she was an independent State. A very great compliment was due to Siam for her original advance, for it was almost entirely original, into civilisation. She had taken precedence of all those nations that surrounded China in the manifestation of her desire to adopt European civilisation as the one means of preserving her independence and developing her own powers. Still it was impossible to regard her position without a good deal of apprehension, quickened by the sympathy that it was impossible not to feel with her for the reasons he had stated. She was a small power which certainly could not extend her boundaries; she was alongside the protectorate of a great power which was certainly manifesting an intention, if not to absorb her, at all events to encroach on her limits; and she had, within herself, nothing to bear up against difficulties so tremendous. From the paper just read, it was evident that there was some slight danger of a difficulty at home, viz., that the means which civilisation would apply to the development of her resources, and to the maintenance of those means she still possessed, would hardly develop themselves with sufficient rapidity; and he could not contemplate the condition of the Laos without certain misgivings that they must be destined to disappear; and that, too, probably for want of greater readiness to adopt such resources as were relied on in India, the teak forests—now solely worked by them—would share the fate of the camphor forests in Formosa.

The vote of thanks having been unanimously passed,

Mr. SATOW, in acknowledging the compliment, said the paper might be somewhat dull, but that arose from the fact that it was simply a plain narrative of what had occurred; and there had been no attempt to dress up any incidents, so as to give them a picturesque or romantic character.

Miscellaneous.

MOSCOW ELECTRICAL EXHIBITION.

Information respecting an Electrical Exhibition, to be held at Moscow in the course of the present year, under the superintendence of the Moscow Section of the Imperial Russian Technical Society, has been received from the Foreign-office through the Science and Art Department. The Russian ambassador has communicated to the Marquis of Salisbury the invitation to exhibit of his Government, addressed to those interested in Electricity. The Exhibition will consist of the following groups:—

1. Electric light; Transmission of force.
2. Telegraphy and Telephony.
3. Electro-technology (Electro-Metallurgy, Electrolysis, the Galvanoplastic art, &c.); Electricity as applied in the railway service, the marine, the military science, in medicine, domestic economy, &c.
4. Electric Piles; Condensers; Static Machines; Thermo-Electric Batteries; Magneto and Dynamo Electric Machines; Transformers; Electro-Motors.
5. Motive power; various boilers; Motors used in Electro-Technics.
6. Measuring and precision instruments; scientific apparatus.
7. Novelties in whatever branch of industry.
8. Literature, plans, designs, diagrams, &c., referring to Electricity.

The Exhibition will be opened on the 14th April, and closed on the 14th October. Applications for space are now being received.

Foreign products destined for the Exhibition are imported Custom-free into Russia, provided they be sent back within a month after the close of the Exhibition, or in case of their being offered as gifts to the Imperial Russian Technical Society. The Custom-house charges must be paid when the exhibits are being sold at the Exhibition.

The gifts offered by exhibitors to the Moscow Section of the Imperial Russian Technical Society will serve to form a museum or an electro-technical laboratory.

Correspondence.

SERICULTURE IN ASIA MINOR.

In May, 1885, the writer was enabled, from personal observation on the spot, to report upon the silk

harvest of Bournabat, near Smyrna, Asia Minor, which report was printed in the *Journal* (vol. xxxiii., p. 852). The sericultural industry was then in a state of slow revival from a condition of almost utter collapse, caused by the deadly effects of the various silkworm diseases which had long devastated, and nearly ruined, the "magnaneries" of France and Italy. Subsequently, in 1887, in an extended and illustrated form, the report was reproduced, with additional sericultural and other information, in the volume entitled "Pen and Pencil in Asia Minor," published by Sampson Low & Co. On both these occasions the writer endeavoured to interest the public in the story of an effort, on the part of an English gentleman, to benefit the Turkish peasantry and revenue of the country, which had more of the romantic element in it than is usually to be found in ordinary industrial operations. For nearly half a century, Mr. John Griffitt, of Bournabat, a village near Smyrna, has devoted most of his leisure hours, well seconded by his accomplished Greek wife, to combatting the maladies of silkworms, experimenting with the various known races, and endeavouring to improve the quantity and quality of their silken produce. Long before M. Pasteur, the distinguished French physiologist, took the field, Mr. Griffitt had been working at the same problems, the solution of which brought the great Frenchman afterwards so much well-deserved honour; but while the one was rewarded, the other has hitherto been neglected. The first enjoyed the wealth and influence of his Government to encourage him in all his efforts; the second has had to struggle on unaided throughout his long career of philanthropic endeavour against the inertia of sluggish or hostile officials, the childishness of a prejudiced peasantry, and a horde of unscrupulous native and foreign parasites, ever ready to appropriate his methods without acknowledgment, to claim or dispute his discoveries, and to defraud him in every possible way. From the first, Mr. Griffitt welcomed and applauded the remarkable results of M. Pasteur's investigations, and became his acknowledged disciple; but, being himself a practical silk-farmer, which M. Pasteur was not, was soon in a position to shoot ahead of his master, to modify, supplement, and stamp with his own genius many of the suggestions of the great chemist, for which he never received either credit or reward. Probably in no other country in the world, except Turkey, could a native, or even a foreigner, accomplishing the revival of a staple industry as Mr. Griffitt has done, have escaped recognition, or being loaded with honours. He has rescued sericulture, upon which so many thousands, perhaps millions, depend in Turkey, from extinction, and been a means of replenishing the usually collapsed Ottoman exchequer, and enabling the Porte to offer British bond-holders—if it chooses to do so—substantial dividends, instead of mere polite excuses.

Still more recently the writer had a paper in the *Journal* of 23rd August, 1889 (vol. xxxvii., p. 772), when further information was given regarding Mr. Griffitt's continued successes, particularly in open-air sericulture. On the present occasion, he would add the latest facts, which are quite as interesting as those already communicated.

At the beginning of 1891 a report by the "Chambre des Deputés" was presented to the French Government, in which it was said that sericulture was not progressing in France in consequence of the re-appearance of the dreaded disease known as "flacherie," along with some minor maladies, and that the nurseries were being decimated. M. Pasteur's discoveries had enabled the silk-farmers to vanquish the other distemper "pebrine," but "flacherie" was working havoc everywhere, so a grant of several millions of francs was asked to be expended in trying to crush the disorder.

Meanwhile, Mr. John Griffitt, with no Government money or help of any kind, had thoughtfully built up a system of scientific silk farming at Bournabat, near Smyrna, in which he combined the most notable of M. Pasteur's discoveries with the invigorating method of M. Roland, of Switzerland, and his own experiences, with the result that his worms acquired such robustness that he had had no deaths among them for years, while all the races, subjected to the process, yielded a larger crop of better silk than before. So marked was this improvement that a comparison will show it at a glance. In the first report already alluded to, made in 1885, Mr. Griffitt's yield of cocoons—considered a splendid return at the time—was 78 kilogrammes (171 lb. avoird.) per ounce of eggs set to hatch, while in 1890 the harvest was 91 kilos. (200 lb.) per ounce of eggs. These figures have been vouched for by M. E. Charmand, chief of the Smyrna branch of the "Direction Générale de l'Administration de la Dette Publique Ottomane, à Constantinople," who reported his observations, gathered from time to time in Mr. Griffitt's factory at Bournabat, to his superiors at the Turkish capital.

Following up these efforts, and stimulated by the ill-success of the French sericulturists, Mr. Griffitt last year achieved an additional triumph, his latest crop showing an advance to 92 kilos. (202 lb.) of cocoons per ounce of eggs. This harvest had likewise been watched through all its stages, and reported upon to the Constantinople authorities by the same gentleman already named, who added that as the yield from foreign eggs had been *nil* at Bournabat, their importation into Turkey ought to be stopped.

It will be evident to the readers of the above and former communications that Mr. John Griffitt's single-handed and almost phenomenal success in sericulture, in the face of the utter failure of the best silk-farmers of France, point to Bournabat as the future sericultural school of the world, and as the *entrepôt* for robust graine. If further figures be required, they are to be found in the circumstance that during the last four or five years the finest French eggs hatched at Bournabat have only yielded

from 10 to 12 kilos. (22 to 26 lb.) of cocoons per ounce, as compared with Mr. Griffitt's 92 kilos. (202 lb.) per ounce of eggs; while last season, according to M. Charmand, the French eggs laid out at Bournabat did not hatch at all.

In a word, if this industry is an important financial consideration to Mr. Griffitt, it can be no less so to the Turkish Government; and the British bond holder of the Turkish debt ought to have every inducement in stirring up the sluggish officials of Constantinople to encourage and befriend a gentleman who is now, and has been so long, working for all their interests.

WILLIAM COCHRAN.

Overdale, Dunblane, Perthshire.

General Notes.

GERMANY AT THE CHICAGO EXHIBITION.—The Berlin correspondent of the *Standard* states that the Reichstag has discussed the proposed grant of 900,000 marks (£45,000 sterling), to assist German industry at the Chicago Exhibition. Almost all the members who spoke were in favour of the grant, as the object of it was to demonstrate to Americans, Eastern Asiatics, and Australians what German manufacturers can do, and thereby to increase, or at least maintain, Germany's export trade. The spokesman of the Government pointed out, that for German industry to remain reserved, would, in view of the strong competition of the Americans, be highly injudicious. It would be very disadvantageous for Germany to sulk in a corner. The only opposition to the grant came from the Protectionist iron manufacturer, Baron Stumm, but his opposition was in vain.

JAPAN AT THE CHICAGO EXHIBITION.—The Chicago *Inter-Ocean* states that the Japaneses Parliament has appropriated 631,000 yen (£125,000) for the purpose of placing the Japanese exhibit at the Chicago Exposition. This indorsement of Parliament has enabled the Government to map out the Japanese exhibit on the lines proposed, and has given confidence to future endeavours. The preparations for the exhibit have been very elaborate, and include the exhibition of the customs, habits, shops, and bazaars of the people. The Press, the officials, and others interested have kept the Exposition well before the people, and future exhibitors have been and are very active. The general result in the passage of the appropriation Bill for the Chicago Exposition meets with universal favour. The Japanese Press is enthusiastic, and the industrial and arts' societies are well pleased. The Bill, as passed by Parliament, anthorises the Government to expend the aggregate sum of 630,765 yen, covering a period of four years as follows:—1891, the sum of 51,495 yen; 1892, 313,098 yen; 1893, 241,536 yen; 1894, 24,635 yen. The expenditures of 1891 are for preliminary organisation, and that of 1892 for the preparation of exhibits; that of 1893 will be devoted largely to transportation, and that of 1894 is to be devoted to closing up affairs.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock:—

JANUARY 27.—F. W. EDRIDGE-GREEN, M.D., "The Scientific Value of Lovibond's Tintometer." R. BRUDENELL CARTER, F.R.C.S., will preside.

FEBRUARY 3.—T. PRIDGIN TEALE, "Dust, and How to Shut it Out." Dr. T. E. THORPE, F.R.S., will preside.

FEBRUARY 10.—E. PRICE EDWARDS, "Burning Oils for Lighthouses and Lightships." Sir LYON PLAYFAIR, K.C.B., F.R.S., will preside.

FEBRUARY 17.—Capt. F. E. YOUNGHUSBAND, "The Pamirs."

FEBRUARY 24.—Mr. ERNEST HART, "Ancient and Modern Art Pottery of Japan."

MARCH 2.—Prof. VIVIAN B. LEWES, "Spontaneous Ignition of Coal, and its Prevention."

Papers, the dates of reading of which are not yet fixed:—

"Iceland." By TEMPEST ANDERSON, M.D.

"The Fisheries Department: its Position and Prospects." By J. W. WILLIS BUND.

"The Congo State." By Captain V. LOVETT CAMERON, R.N., C.B.

"Durability of Pigments Ground in Oil and other Vehicles." By A. P. LAURIE, M.A.

"Manufacture and Industrial Application of Flexible Tubing." By GILBERT R. REDGRAVE.

FOREIGN AND COLONIAL SECTION.

Tuesdays, at Half-past Four or Eight o'clock; due notice of the hour will be given:—

FEBRUARY 16—LEWIS ATKINSON, "The Forthcoming Exhibition at Kimberley." 8 p.m. The paper will be illustrated by lantern slides.

MARCH 15.—F. A. PEZET (Peruvian Consul General), "Peru." 8 p.m.

APRIL 5.—The Rev. JOHN MCLEAN, D.D. "Manitoba and the North-West Provinces of the Dominion."

APRIL 26.—Sir EDWARD BRADDON, K.C.M.G., "The Progress of Australasia."

MAY 24.—Colonel HOWARD VINCENT, C.B., M.P., "The Extension of Colonial Trade."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

FEBRUARY 11.—LORD LAMINGTON, "Recent Travels in Indo-China." Lieut.-General Sir ANDREW CLARKE, G.C.M.G., C.B., C.I.E., will preside.

MARCH 3.—Surgeon-General Sir WILLIAM JAMES

MOORE, K.C.I.E., "Indian Sanitation and the International Congress of Hygiene." Major-Gen. Sir OWEN TUDOR BURNE, K.C.S.I., C.I.E., will preside.

MARCH 24.—G. H. M. BATTEN, formerly of the Bengal Civil Service, "The Opium Question." Sir JOHN STRACHEY, G.C.S.I., C.I.E., will preside.

APRIL 7.—Dr. J. AUGUSTUS VOELCKER, "The Agricultural Needs of India."

APRIL 28.—Sir WILLIAM WEDDERBURN, Bart., "Reorganisation of Agricultural Credit in India." The Right Hon. Sir JAMES CAIRD, K.C.B., will preside.

MAY 19. — JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock :—

JANUARY 26.—WILLIAM MORRIS, M.A., "The Woodcuts of Gothic Books." Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., LL.D., M.D., will preside. The paper will be illustrated by lantern slides.

FEBRUARY 23.—J. WILLIAM TONKS, "Artistic Treatment of Jewellery: Jewel and Address Caskets."

MARCH 29.—E. ROSCOE MULLINS, "The Decorative Uses of Sculpture." ALFRED GILBERT, A.R.A., will preside.

APRIL 12. — C. PURDON CLARKE, C.I.E., "English Brocades and Figured Silks."

MAY 17.—GEORGE J. ROBINSON, "Decorative Plaster Work" (II.). J. HUNGERFORD POLLEN will preside.

CANTOR LECTURES.

Monday evenings, at Eight o'clock :—

PROF. GEORGE FORBES, F.R.S., "Developments of Electrical Distribution." Four Lectures.

LECTURE I.—JANUARY 25.—Low pressure supply—Comparison between 1885 and 1892—Central stations *versus* isolated plants—Electricity *versus* gas—Cost of feeders and distributing mains—Management of feeders—Use of recording apparatus—House wiring—Three-wire system—Five wires—Use of motor-dynamos as compensators—Batteries—Conductors.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JAN. 25...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Prof. George Forbes, "Developments of Electrical Distribution." (Lecture I.)

Royal Scottish Society of Arts, George-street, Edinburgh, 8 p.m. 1. Mr. Wm. Bruce, "Improvements in Cement and Concrete Testing Apparatus." 2. Professor Blyth, "The Application of Wind Power to the Generating of Current Electricity."

British Architects, 9, Conduit-street, W., 8 p.m. Presidential Address to Students.

Actuaries, Staple-inn-hall, Holborn, 7 p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Arnold Mitchell, "The Vaulted Roofs of the Middle Ages."

TUESDAY, JAN. 26 ... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. William Morris, "The Woodcuts of Gothic Books."

Society of Architects, St. James's-hall, Piccadilly, W., 8 p.m. Professor J. Logan Lobley, "Building Stones; their Structure and Origin."

Royal Institution, Albemarle-street, W., 3 p.m. Professor Victor Horsley, "The Brain." (Lecture II.)

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. Wilfrid Airy's paper, "Weighing-Machines." 9 p.m. Reception by the President and Council.

Photographic, 5A, Pall-mall East, S.W., 8 p.m.

Anthropological, 3, Hanover-square, W., 8½ p.m. 1. Annual General Meeting. 2. Rev. Dr. John McLean, "The Blackfoot Indian Confederacy with adjacent Tribes at the Rocky Mountains."

WEDNESDAY, JAN. 27...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. F. W. Edridge-Green, "The Scientific Value of Lovibond's Tintometer."

Meteorological, 25, Great George-street, S.W., 7½ p.m. 1. Annual Meeting. 2. Address by the President (Mr. Baldwin Latham), "Evaporation and Condensation."

Patent Agents, 55, Chancery-lane, W.C., 7½ p.m. 1. Discussion on Mr. Abel's and Mr. Loubier's papers. 2. Mr. A. V. Newton, "Patent Agency: its Origin and Uses." 3. Mr. G. B. Ellis, "Compulsory Licenses."

Entomological, 11, Chandos-street, W., 7 p.m. Annual Meeting. Address by the President, Mr. F. D. Godman.

Royal Society of Literatnre, 21, Delahay-street, S.W., 1 p.m.

THURSDAY, JAN. 28...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury-circns, E.C., 6 p.m. Mr. E. B. Poulton, "The Methods by which Animals Conceal themselves."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. A. S. Murray, "Some Aspects of Greek Sculpture in Relief." (Lecture II.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Inaugural Address by the President, Prof. W. E. Ayrton.

FRIDAY, JAN. 29...United Service Institution, Whitehall-yard, 3 p.m. Rear-Admiral Samuel Long, "An Attempt to Estimate the Probable Effect of the Introduction of Quick Firing Guns on Naval Tactics and Construction."

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m. Sir George Douglas, "Tales of the Scottish Peasantry."

Civil Engineers, 25, Great George-street, S.W., 7½ p.m. (Students' Meeting.) 1. Mr. William H. D. Cleminson, "The Evolution of Rotating Projectiles." 2. Mr. D. Carnegie, "The Manufacture of Forged Steel Projectiles."

SATURDAY, JAN. 30 ... Frœbel Society, at the HOUSE OF THE SOCIETY OF ARTS, 2½ p.m.

Saturday Lecture Society, Lecture Theatre, South Kensington Museum, S.W., 3 p.m. Capt. W. de W. Abney, "The Action of Light on Pigments."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Fleming, "The Induction Coil and Alternate Current Transformer." (Lecture II.)

Journal of the Society of Arts.

No. 2,045. Vol. XL.

FRIDAY, JANUARY 29, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

HOWARD LECTURES.

Owing to the illness of Prof. W. C. Unwin, F.R.S., who is laid up with the influenza, the delivery of the course of lectures on "The Development and Transmission of Power from Central Stations," announced for February 5, 12, 19, 26, and March 4, 11, will be postponed.

CANTOR LECTURES.

Prof. George Forbes, F.R.S., delivered the first lecture of his course, on "Developments of Electrical Distribution," on Monday evening, 25th inst. The lectures will be printed in the *Journal* during the summer recess.

Chicago Exhibition, 1893.

ELECTRICITY COMMITTEE.

The first meeting of this Committee was held on Tuesday afternoon, 26th inst. Present: W. H. Preece, F.R.S., in the chair; Sir Frederick Abel, K.C.B., D.C.L., F.R.S., Colonel R. T. Armstrong, C.B., R.E., R. E. B. Crompton, Prof. James Dewar, M.A., F.R.S., Major-General E. R. Festing, F.R.S., Prof. George Forbes, M.A., F.R.S., Prof. G. Carey Foster, F.R.S., Edward Graves, Prof. D. E. Hughes, F.R.S., Gisbert Kapp, J. C. Lamb, C.M.G., W. M. Mordey, J. Fletcher Moulton, M.A., Q.C., F.R.S., Prof. John Perry, D.Sc., F.R.S., Alexander Siemens, Prof. Silvanus P. Thompson, D.Sc., F.R.S., with Sir Henry Trueman Wood, Secretary of the Royal Commission.

DEPARTMENT OF AGRICULTURE.

The following correspondence respecting the Cereal Exhibits has been forwarded to the Secretary of the Royal Commission :—

World's Columbian Exposition,
Department of Foreign Affairs,
Chicago,
January 11th, 1892.

To Sir Henry Trueman Wood,
Royal British Commisson,
London.

Sir,—I have the honour to transmit for your consideration a letter from the Chief of Department of Agriculture in regard to the character and importance of the cereal exhibits at the Exposition, which it is to be hoped will comprehend products of all the nations participating.

We hope to have your highly esteemed co-operation in this matter, and will take great pleasure in receiving any communication upon the subject which you may desire to make.

I am, sir,
Your most obedient servant,
(Signed) Walker Fearn.
Chief, Department Foreign Affairs.

Office of the Director-General,
World's Columbian Exposition,
Chicago, Ill., U.S.A.,
January 9th, 1892.

Hon. Walker Fearn,
Chief, Department of Foreign Affairs,
World's Columbian Exposition.

Dear Sir,—I have the honour to request that you call the attention of representatives of Governments who have accepted the invitation of this Government to participate in the Exposition to the character and importance of the cereal exhibit contemplated, and being arranged by this Department for the Exposition.

In order that the official classification relating to "cereals, grasses, and forage plants" may be comprehended, I beg to quote from said classification the classes comprising the same, as follows :—

Class 1. Wheat and its culture. Varieties of wheat grown in America and abroad; statistics of products and of prices.

Class 2. Indian corn—all varieties. Illustrations of methods of planting, tilling, and harvesting; statistics of products and of prices.

Class 3. Oats.

Class 4. Barley.

Class 5. Rye.

Class 6. Rice and its culture.

Class 7. Buckwheat and other grains.

Class 8. Grasses, various species; hay and hay-making.

Class 9. Forage plants—clover, alfalfa, cow-pea, cornstalks.

Class 10. Ensilage—silos, &c.

Class 11. Flours, meals, decorticated grains, grits, &c.

Class 28. Potatoes, sweet potatoes, yams, &c.

Class 29. Sugar, beets, mangel-wurzel.

Class 30. Carrots, turnips, beets, artichokes, &c.

Class 31. Peanuts; methods of cultivation, statistics, &c.

Class 32. Broom corn, pumpkins, squashes, pease, beans, as crops.

Class 17. Sugar-cane, its cultivation and treatment; manufacture of sugar.

Class 45. Tea, coffee, cocoa, chocolate, and substitutes.

Class 46. Hops; culture, statistics, &c.

Class 48. Tobacco in the leaf, and tobacco not manufactured.

Class 53. Cotton on the stalk—its several varieties; long and short staples, shown by living examples, by engravings, photographs, &c.

Class 54. Methods of planting and culture.

Class 59. Hemp, flax, jute, ramie, and other vegetable fibres not enumerated, in primitive forms and in all stages for spinning.

Class 60. Wool in the fleece, in sacks and in bales.

Class 61. Silkworms, silk in the cocoon; apparatus and appliances used in silk culture.

It is the desire of this Department that the exhibit of these products be as complete and exhaustive as it is possible to make it; in brief, that it shall include illustrations, with methods of culture, &c., of the leading varieties grown in every part of the civilised world. A very complete exhibit of this character will be made from all the States of the United States; and the co-operation of the various State Commissions in this work has been fully accorded this Department, and the work of preparing the same is now being carried on.

Among important features, it may be mentioned that there will be a special display of potatoes and other tubers during the two weeks beginning Monday, September 11, 1893, and a special display of sugar beets during the two weeks beginning October 9, 1893. These will be in addition to the regular exhibit, and will be of products grown during 1893. Illustrations of planting, harvesting, important processes connected with the manufacture of food products, systems of irrigation and drainage, and all subjects connected with farm work will be presented in proper form. In brief, there will be an exhibit from this country which will fully illustrate the progress made in agriculture, and the productive capacity of the soil of the different States.

It is the earnest desire of the Director-General, and of this Department, that an equally complete and comprehensive exhibit of farm products shall be made by all the nations which will take part in the Exposition. With the earnest and active co-operation of foreign Governments, an exhibit of farm products may be made which will give visitors a clear and definite idea of the world's progress in agriculture, and afford an instructive object lesson as to the best methods to be employed in cultivation, and other valuable information.

Exhibits of cereals should be accompanied by the following information:—(*a*) Name of object; (*b*) name of producer; (*c*) place where grown; (*d*) character of soil; (*e*) date of planting; (*f*) quantity of seed planted per acre; (*g*) method of cultivation; (*h*) date of harvesting; (*i*) yield per acre; (*j*) weight; (*k*) price of product at nearest home market; (*l*) average temperature, by months, for the time intervening between planting and harvesting; (*m*) average rain or snow fall, by months, for the time intervening between planting and harvesting; (*n*) was exhibit produced by irrigation?

May I request you to ask foreign countries to include in their exhibits specimens of farm crops in such quantities as they may decide upon, as indicated above, and thereby add to the general interest of the Exposition.

This Department will gladly furnish any information desired relative to such an exhibit, and will be obliged if you will request a reply to this letter.

I have the honour to be,

Very truly yours,

(Signed), W. I. BUCHANAN,

Chief, Department of Agriculture.

Proceedings of the Society.

INDIAN SECTION.

Thursday afternoon, January 21st, 1892; Sir W. W. HUNTER, K.C.S.I., in the chair.

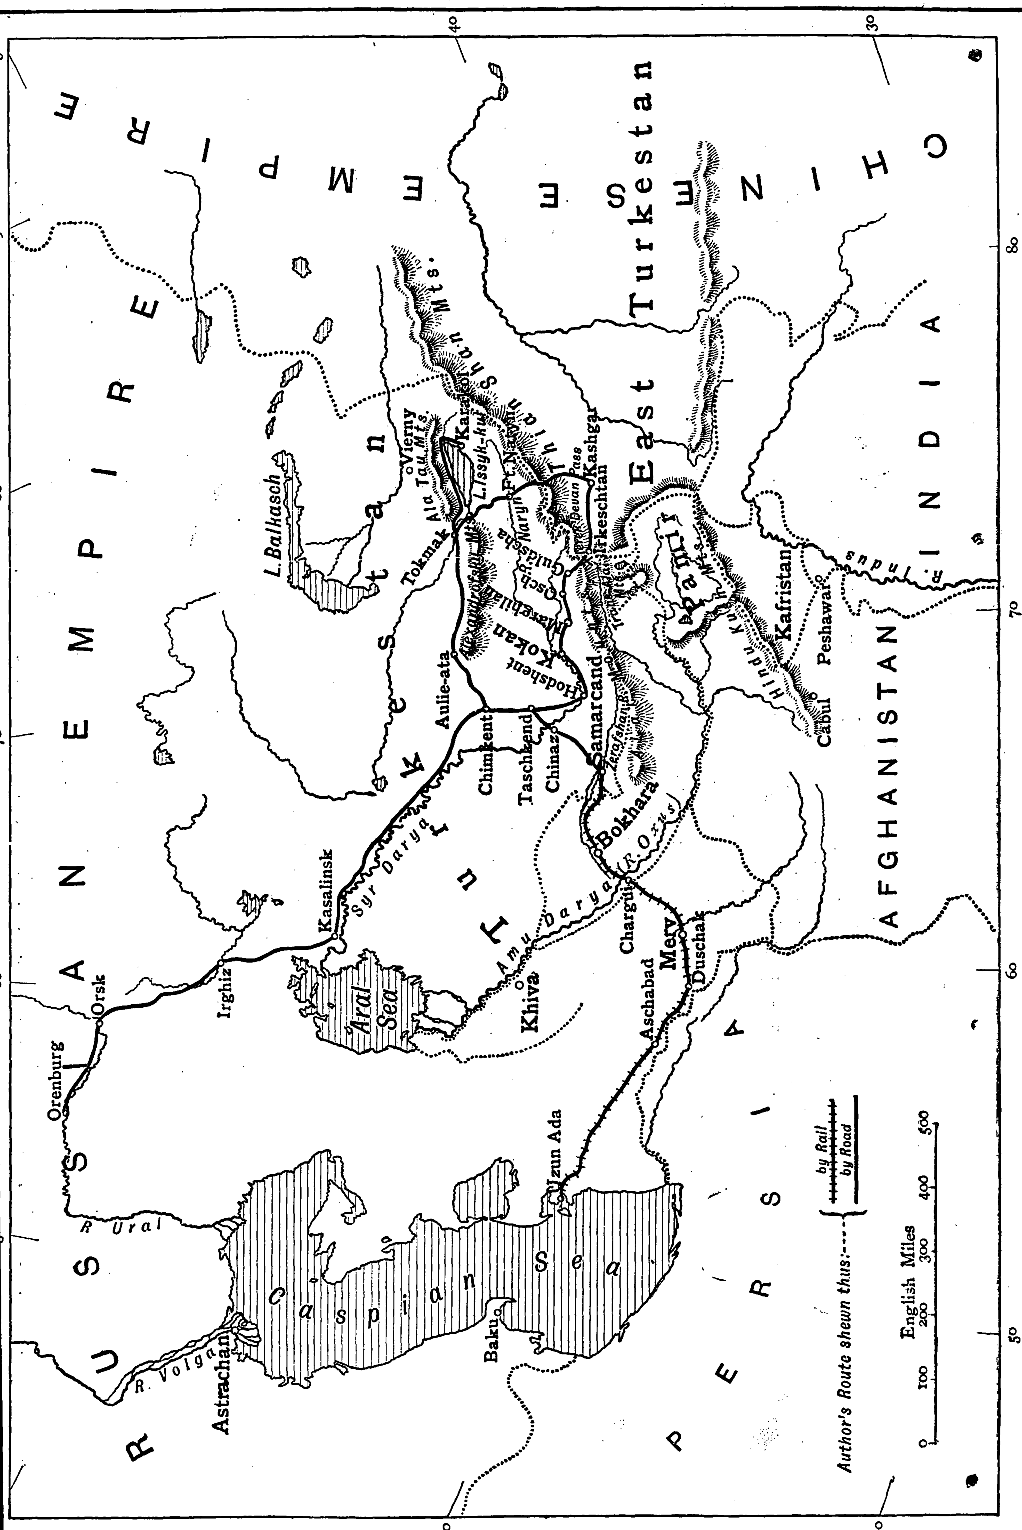
The paper read was—

FROM TIAN SHAN TO THE PAMIRS: EXPERIENCES ON THE RUSSO-CHINESE FRONTIER.

By HERBERT JONES.

Events sufficiently well known to the members of the Society of Arts have recently attracted the attention of the civilised world to the remote highlands of Central Asia, through whose solitudes are now traced the somewhat uncertain boundary lines of three great empires, the British, the Russian, and the Chinese.

To Englishmen the main points of interest are doubtless those connected with the frontier of our Indian Empire, and of the States immediately adjacent thereto. But this part of the Asian highlands did not come within the scope of my journey; it has, moreover, been recently treated of by some of our greatest living authorities. I propose, therefore, in the present



Walker & Boutall sc.

paper, briefly to describe my own impressions of that portion of the Russian Empire which abuts on the Chinese frontier, from the western slopes of the Tian Shan to the valleys of the Trans Alai, which form the approaches to the Pamirs from the north.

This portion of the Russo-Chinese frontier may be fairly described as a scientific one; excepting the comparatively level country up the valley of the Ili leading to Kuldscha, the frontier is traced along a line of practically inaccessible mountain peaks and ridges, intersected by a few passes such as the Narinkol Musart, Bedel, Turugart, &c., difficult not so much from their height (some 11,000 or 12,000 feet) as from the absence of roads and bridges on both sides of the frontier.

But further south the frontier lines between the Russian province of Ferghana and the Chinese one of Kashgar are drawn so that the important Terek Davan Pass (13,500 feet) is entirely within Russian territory; and the Cossack fort of Irkeschtam, which marks the Russian boundary on the road to Kashgar, is practically among the foothills which bound the Kashgar plain, and also commands the head waters of the Kizil Su. This river flows down the Alai valley, which is bounded on the south by the ranges of the Trans Alai and Mustagh Tau mountains, with the Kizilart and other passes leading up to the series of table lands and ravines known as the Pamirs. This Russian territory is divided into two portions by the River Naryn, as the upper reaches of the Syr Darya are called, into the province of Semerechia (in English, Seven Stream Land), to the north of the River Naryn, and the province of Ferghana, to the south of it, a country which, prior to the Russian occupation, formed the Khanate of Kokan.

Semerechia bas been described by Russian writers as an "Asiatic Switzerland;" it might with more accuracy be termed an "Asiatic Colorado."

The average temperature approximates to that of southern Germany; but the maxima of heat and cold exceed those of central Europe. Owing, however, to the elevation of the greater part of the country above the adjacent steppes of Turkestan, the extreme summer heat which afflicts the lowlands is not experienced in Semerechia; and the pure dry mountain air and bright sunshine cause the sharp frosts of the short winter season to be less felt.

Although the winter snowfall is sometimes considerable, the dryness of the atmosphere obviates the fearful discomfort of the spring thaw, which, in European Russia, converts roads into impassable quagmires, and town streets into rivers of liquid filth, laden with the accumulated refuse of a five months' frost.

Here, on the contrary, the sun evaporates rather than thaws the snow, and a couple of days' warm wind towards the middle of February causes the snow to vanish from the plains like the shadow of a cloud, leaving only a drift here and there in the hollows of the ground, through which the steppe crocuses are already pushing their impatient heads.

The snow on the foot hills disappears in March, causing a considerable rise in the rivers, which then subside to their normal depth until towards the end of May, when the thawing of the snow on the high alps and glaciers causes a second and still greater rush of water. The absence of bridges, and the fact that the approaches to many of the passes lead up ravines which form the bed of a mountain torrent, render this second flush a very troublesome obstacle to communication in summer, especially in some directions where, owing to the extreme steepness of the mountain slopes, the roads are closed altogether in winter by avalanches.

The mountains of Semerechia may be described as the western spurs of the Tian Shan, the chief of which are marked in our maps as the Ala Tau and Alexandrofsky ranges.

The Ala Tau ranges are divided by Lake Issik-kul into two divisions, known respectively as the Kungei (sunny) Ala Tau on the north of the lake, and the Ters (shady) Ala Tau to the south of it.

In this dry climate rain is almost unknown, and vegetation depends on the snow accumulated on the mountain slopes. Those slopes which are exposed to the sun soon lose their moisture, and they and the plains beneath are soon parched into absolute barrenness; but wherever the snow lies there trees can grow, which in turn afford further protection to the mountain stream.

Although Semerechia derives its name from its rivers, these are geographically less interesting than the lakes of fresh, brackish, and salt water with which the country abounds. First, in point of size, is the great lake Balchash, but its position far out in the barren steppe deprives it of any economic importance, in which respect by far the most important is Lake Issik-kul, a magnificent sheet of slightly brackish water, some 120 miles long by about 40 broad at its widest part. Issik-kul is about 5,500 feet, Lake Sairam Nor, in Kuldscha, 7,200,

and the lonely Son Kul, in the south of the province, 9,400 feet above sea level. The larger lakes are usually brackish, and small lakes of very salt water are found in various parts of the province.

A description of Semerechia would be incomplete without a reference to Kuldscha, a Chinese province on the upper waters of the Ili river.

This fertile oasis in the midst of the Mongolian wilderness of rocks and deserts presents a striking parallel to the position of Egypt in another continent. Like Egypt it is renowned for its climate; the traveller from Turkestan sees the last of the grapes which so abound in the southern provinces when he reaches Chimkent, and whilst Vierny, the capital of Semerechia, is famous for its apples, the Issik-kul valley has not yet succeeded in producing this fruit. But at Kuldscha, considerably further north than both of these places, both apples and grapes grow and ripen freely in the open air, owing to the protection of the mountain ranges of the northern Tian Shan.

Moreover, Kuldscha was the home of an industrious Mohamedan population, which drove out its rulers at the time of the Tæping revolt, and the subsequent disorders led to foreign intervention. Russian troops occupied for a series of years the province, the key and granary of Western Mongolia, and in reply to the protests of China, that power was assured that as soon as she could give satisfactory guarantees of the maintenance of order on the frontier Kuldscha would be restored to her. These conditions having been fulfilled, the Russian Government has honourably carried out its undertaking, and the Chinese have resumed possession of the revolted province.

In view of the criticisms of Russian earth-hunger, of which we hear so much at present, this retrocession of Kuldscha should not be overlooked as a fact on the other side.

The troubles in Kuldscha had considerable influence on the population of Semerechia, because the Chinese Mohamedans, known by the name of Dungans, mostly elected to follow the Russian troops, and quitted the country rather than submit again to the Chinese Mandarins. On the other hand, some nomad tribes of Kalmucks, who previously dwelt in the steppe around the north end of Lake Balkash, have transferred their allegiance to their Buddhist co-religionists in Kuldscha.

The aboriginal mountain population of Semerechia are Kara Kirghis, of the division called Diko-kammenye (Wild Mountain), but in the steppe beyond Vierny, there are many Kazak Kirghis. The mountain Kirghis are a more settled people than the nomads of the steppe, to whom they are distinctly superior, both physically and mentally; they are a good-tempered, indolent race of shepherds and cattle tenders, excellent riders, and fond of field sports, especially horse-racing and falconry. Although in many places they are sufficiently settled to house their stock in sheds in winter, they almost invariably retain the *yourt*, or felt tent, of the steppe for their own residence.

The native townspeople are of the mixed race, known throughout Turkestan as *Sart*, a people, doubtless, of Tajik (Iranian) origin, but so mixed with Tartar and Mongolian races, that the original type is often scarcely recognisable.

The Dungans—already alluded to—are a brave, honest, and industrious people, which has already made its influence felt as far as Taschkend and beyond. They have become the carriers of Central Asia, wherever wheeled transport is possible; and their trustworthiness is so much greater than that of the Russian peasants, or Sart Arabadgis, that they have almost monopolised the trade in the north.

The Russian colonists in Semerechia are a very heterogenous body, but are divisible into two main sections—one composed of peasants, chiefly from the Tomsk and other Siberian Governments; the other, military colonists, time-expired soldiers, and Cossacks.

The general appearance of these settlements is not creditable to the inhabitants. Surrounded with every advantage of fertile land, plenty of water, wood, and building material that a colonist could desire, the moujik remains precisely the same shiftless, slovenly, unprogressive creature as before. It would cost him next to nothing to build a decent house, but he and his family still herd together in one little room, like a litter of pigs; he has not a bed to sleep on, nor a chair to sit down upon; and the meanest Kirghis *yourt* is more artistically decorated than his grimy unventilated *izba*. His farmyard is kneedeep in dirt, and his cattle pens are built, if possible, beside a running stream, so that he can throw the manure into it and have it washed away without further trouble. The profits of his abundant harvests are spent in disgraceful orgies, the immediate excuse for which is usually a wedding in the village. The demoralisation induced by these Bacchanalian habits is spreading from the Christian to the

Mohamedan population, and is causing a serious increase in theft and other crimes on the part of the hitherto orderly Kirghis.

Considering that Russia has now been in undisturbed possession of this glorious country for well on to half a century, and has, moreover, the advantage of direct water and rail communication by the Volga and Kama to Perm, and the Ural railway to Tioumen, and thence by river right away to Semipalatinsk on the frontier of the province, its present backward condition seems scarcely commensurate with the resources of its possessor, or the general progress of the world. Did time permit, it would be interesting to compare the development of this land under Russian auspices, with that of another, whose settlement under British influence and not very dissimilar conditions, commenced about the same time—I refer to New Zealand. I will only remark that our colony has solved the question of the disposal of its surplus flocks and herds, whilst cuts of beef are still selling in Karakol for 1½ copecks per pound for which people in Moscow are paying over 50 copecks, whereas Russian cheese is retailed in the Central Asian shops at 60 copecks per pound, in a land where the value of a cow is 8 roubles or in other words less than the price of a single stone of cheese. The Russian government does all in its power to improve agriculture, but all efforts have failed to overcome the stolid apathy of the settlers.

My own acquaintance with the Semerechia province dates from November of 1890, at which time I arrived there along the post road, which runs from Samarcand and Taschkent to Vierny and Semipalatinsk, on the Irtish river. It was not an agreeable journey at that time of year. From motives of economy the supply of horses on the road has been reduced to the absolute minimum necessary to carry the mails, and the hopeless traveller is condemned to pass weary hours at wretched little desert stations waiting for a relay of horses. Passing at last the little town of Tokmak, I diverged from the north road and commenced the ascent of the ravine of the Chu river by a military road, made a few years ago by Russian engineers, and looked upon as one of the most difficult engineering feats in the country. This ravine is known as the Buamsky Uschelye, and is a deep gorge or canon, through which rushes the Chu, an eccentric stream, which is widest and deepest at its upper end, but which gradually dwindles lower down, until it disappears in a swamp in the desert. The view which presents itself to the traveller, as he emerges from the canon of the Chu into the broad Issik-kul valley, is one of the most striking in the world. Around him tower the bare rigid heights of absolutely barren mountains, grey, blue, yellow, and red, according to the rock of which they are composed, without a blade of grass to diminish the effect of their vivid colouring. Immense moraines of boulders and gravel slope down to the azure blue surface of the lake, whilst the snow-clad heights of the higher ranges on the Chinese frontier, cold and clear against the glowing Western sky, complete a landscape to which I am unable, in my own experience, to quote a parallel.

Continuing along the post-road eastward on the north shore of the lake, the traveller crosses a wide steppe tenanted by flocks of bustards and other wild birds, and a few Saiga antelope, with occasional Kirghis encampments. The first Russian village is located about midway from each end of the lake, from which point a series of settlements, at about 25 versts apart, are placed along the post-road to Karakol.

This town, now officially designated Prschevalsk, in honour of the celebrated Russian explorer, who died there, is a quiet little garrison town, with wide, straight streets and small one-story houses. However small its importance, politically or commercially, it is an interesting spot to the traveller, who sees here a meeting-point of three civilisations, existing amicably side by side without strife or fusion.

The lower end of the town is occupied by the spacious houses, with more or less elaborate wooden verandahs and pagoda-like roofs, of the Dungan merchants, Chinamen in everything but religion, who have a mosque of their own, and keep apart from the Sarts, whose squalid mud hovels occupy another part of the town. The whitewashed cottages of the Russians occupy the remaining streets. Contrary to the usual procedure in Russian towns, these houses show a reversion from brick and clay to wooden walls, all the newer houses being built of logs in the well-known Russian style. Even the church, dignified by the name of a cathedral, is now closed, and service is performed in a wooden chapel adjacent.

The ruinous state of the villages on the road will have prepared the traveller for this state of things. The one drawback of the country is the fear of earthquake, which is

perpetually before the inhabitants. The great shock three years ago, which laid every house in Vierny in ruins, did great damage in the Issik-kul valley; but Karakol, not being on the line of seismic disturbance, escaped with comparatively little injury; but the small village of the Ui Tal, near by, lost more than a dozen persons out of a population of some 200 souls.

The fruitful soil of the Issik-kul valley produces grain far beyond the requirements of the settlers, who live in hopes of military operations on the frontier, to give them a market for the contents of their overflowing granaries. Horses, sheep, and cattle are equally cheap. On the other hand, manufactured articles are usually about double the prices at which they are retailed in Samarcand, except the indispensible vodki, which is distilled in Vierny, and third-rate beer, brewed in Karakol. It is characteristic of Russian commercial insight that the only large factory visible on the north road is one at Chimkent, erected a few years ago for the production of santonine on a scale which speedily overstocked the whole civilised world with the drug, and the factory had to be closed for want of a market; whilst soap, candles, sugar, matches, cloth, and so forth, are still being imported from Moscow and Poland.

Among the natural products of the Issik-kul valley I may just mention two characteristic ones.

Honey of excellent flavour is obtainable in any quantity by those of the settlers who are sufficiently intelligent to keep bees. The price of the finest quality is about 10 copecks per lb., as against 25 copecks for sugar.

The valleys round about have long been noted as headquarters of the royal eagle, known locally as the "Berkut." These magnificent birds are caught and trained by the Kirghis to capture deer, foxes, and wolves, and are greatly valued by the natives; a good eagle is considered to be worth several horses, and they are in request all over the steppe, and even in Persia and the Caucasus.

In Karakol, as in most other places throughout my journey, the Russian officers, both civil and military, received me in the most friendly manner, and I passed three months there in shooting excursions into the surrounding country, a thoroughly enjoyable time despite the late season of the year.

Having resided in Russia for years, and travelled thousands of miles, unattended and unintroduced, in various parts of the empire, I have had considerable experience of Russian Tchinovinks. In no single instance have I been received otherwise than courteously, and I can recall many instances of friendly consideration quite beyond mere official politeness. The attacks of Jews and Nihilists on the Russian beaurocracy obtain such prominence in the English press, that I feel bound to state my experience in this respect.

Early in February, 1891, I set off on horseback, on my journey from Karakol to Kashgar. As there is a post-road as far as Fort Naryn, I did not take a guide, relying on getting one at the frontier. The road to the Naryn branches off the Karakol tract at the station of Kutemaldi, passes along the west end of Issik-kul, and winds through a series of bare rocky defiles and upland villages, inhabited only by Kirghis. The journey passed without special incident, except the unpleasant experience of a *buran*, what Americans call a blizzard, until I reached the Dolan Pass, not very high, but with a steep descent on the far side, one sheet of ice from top to bottom. Here my horse showed signs of giving out, but I succeeded at last in getting to the station. About 20 miles short of Fort Naryn, however, he stopped again, and I should have probably been all night on the road, had not an empty sledge come along and assisted me.

Fort Naryn is a bare, little place, inhabited by a small garrison and a few Russian and Sart traders. Owing to its height above the sea (some 7,000 feet), and the position of the surrounding hills, it has a very severe climate. When I was there the thermometer registered equal to 27° below zero, Fahrenheit.

I stayed at Fort Naryn for about a week, and obtained an escort of a couple of Cossacks, purchased a few provisions, and set out for Kashgar.

The first stage on the north road is to the village of At-Bashi, the last settlement on the Russian side. As the road is practicable for sledges so far, some of the officers accompanied me, and we had some duck shooting in the valley, which abounds in hot springs. About noon next day we took our leave, and rode up long sloping valleys, and over low hills till evening, where we halted at a rough Sart dwelling.

The station was crowded with a large camel caravan, of which we met several more further on, because all the camel caravans reach Kashgar by this north road, the southern track over the Terek Davan being only available for horses. These caravan camels are the best

and strongest animals obtainable; weak, half-fed beasts, such as you see on the lowlands, cannot stand the hardships of the road.

No beast of burden requires more care to keep it in condition than a camel, and if it once gets weak it requires months to get it into condition again. The drivers take great care of their beasts, and keep them warmly clad in thick felt; even the donkeys on which the merchants ride are jacketted to the tips of their ears—horses and cattle go unclad.

The caravan carries all supplies with it, down to hay and firewood.

It was curious to see the drivers dosing their camels with oil, to keep them in condition. One holds the animals head whilst the other pours the oil down its throat from a bottle, the patient meanwhile spluttering and roaring like a naughty child over a dose of cod-liver oil.

Next night we camped in a Kirghis *yourt*, erected in an old fort at the foot of the Tasch Rabat Pass. On the way we passed many parties of labourers with their few belongings loaded on a donkey, tramping to the Naryn. I learned they were bound for Vierny, where they would hire out to the Russian colonists for the summer. It shows the destitution amongst the poor in Kashgar when able-bodied men are willing to undertake a journey of nearly 500 miles over one of the worst roads in the world to work for strangers at six or seven roubles (12 to 14 shillings) per month.

Next day we climbed the Tasch Rabat Pass, about 11,000 feet high, with a lot of ice at the foot, and descended on to Lake Chatyr Kul, which we crossed on the ice, and beyond it we climbed another pass. At the top are visible two small cairns of stones, the boundary mark of the two empires. The view from this point was one I shall never forget. Far below us the valley of the Touyoun river stretched to the horizon; to the right lay a wilderness of wild bare mountains, whose rigid outlines looked as if they might have been turned out of a mould like an iron casting; whilst on the left, or north-east, rose range over range of the main Tian Shan chain. Passing over the further incidents of the journey, I may say I arrived in Kashgar on the 2nd (14th) March and dismounted at the Russian Consulate there, where I had the pleasure of making the acquaintance of Mr. Petrovsky, who has for many years represented not only Russia but the civilised world in what is, in more senses than one, one of the "dark places of the earth." Himself, one of the most successful of Russia's representatives abroad, Mr. Petrovsky's influence in Kashgar is popularly supposed to be not second to that of the Chinese Dao Tai himself; he, nevertheless, understands to maintain excellent relations not only with the Chinese authorities, but with the Englishmen who occasionally find their way there, and other Europeans have frequently been indebted to him for kindly assistance and advice in dealing with the local mandarins. Russian traders have the right to circulate freely in Kashgar, but other foreigners are not allowed in the country except by special passport from the Isumgli Yamen in Pekin.

This privilege, however, does not appear to have proved of as much practical use to the Russians as might be expected, and I was informed that the few Russian merchants who had attempted to open stores in the city had been compelled to give up the enterprise owing to the tacit agreement among the traders to boycott any European endeavouring to break their monopoly of the import trade. On the other hand, the bazaar contains a large number of Hindoo and Afghan merchants, and the Indian element appears to occupy itself more with actual trade than with money-lending, the main business of the Hindoos in the cities of Turkestan, where they appear to take the place generally occupied by the Jews in European cities. Russian roubles, Indian rupees, Chinese cash, and the native currency, "carcans," are all current in Kashgar.

The recent appointment of a British Consul in Kashgar is an excellent step, only too long delayed. At the time of my visit, the Britisher was made to feel, in various ways, that he must take a back seat, and although, of course, the English intercourse with the country is small, yet the total number of Indian subjects interested in the country is considerable. The poverty of the country is, however, so great that the internal trade does not amount to much, and the Chinese and Russian Governments have stopped the transport of goods from British India into Turkestan, which used to pass this way. The custom-house at Irkeschtam prohibits the import of Indian cotton goods, and the Chinese have stopped the tea caravans from Assam.

I found a small British colony established at Kashgar, two English sportsmen having come up from India in the autumn; Capt. Younghusband and Mr. Macartney were also in the country, but, at the time of my visit, only one gentleman was at home. Having been out of reach of news for some time, it was an unex-

pected treat to see English newspapers, only two months old, in this out-of-the-way place.

After a three days' stay in Kashgar, I resumed my journey. The courier who takes the mails to Osch twice a month was starting, so I took the opportunity of accompanying him. The road on Chinese territory to the frontier fort of Irkeschtam presents no special difficulty.

At the frontier I hired a couple of baggage ponies, to help us over the passes, and purchased various supplies, including a load of firewood, as we should have to camp out under the main pass. The road goes over two lower passes and up a long winding ravine, forming the bed of a frozen stream. The going was abominable; the ice lower down was flooded, and partly thawed, and the horses were constantly breaking through, whilst higher up it was firmer, but very slippery.

Thoroughly tired out, we arrived at length at this camping ground, a bare rock at the foot of the main pass, littered with bales of goods, which had been abandoned by some caravan, but without any protection against the weather. Violent snowstorms cause loss of life at this point nearly every year, but nothing is done. It is safe to say, that in no other Christian country would so important a road be left in such a neglected condition.

After supper we made up a good fire, and lay down to get what sleep we could. I dozed off, and dreamed a bear was biting my toe off, which I found, on waking, meant that I had put my feet too near the fire, and the soles of my felt boots were frizzling. About 3 a.m. I rose, as it was too cold to lie still any longer; and we crouched over the remains of the fire waiting for daylight. As soon as we could see our way, we drank some tea, saddled the horses, and resumed our journey, and about 10 o'clock stood on the top of Terek Davan, 13,500 feet high. The horses appeared to suffer from the thinness of the air, but the day was fine and fairly warm, and we dismounted and made our way down the steep slope on the other side on foot.

All the rest of the day we were descending from the ice-bound solitudes above into the warm springtime of the valley beneath, green with the new grass, and ringing with the songs of the birds. It was like passing in a single day from Christmas to Easter.

The Terek Davan Pass may be regarded as one of the approaches to the Pamir regions; From Irkeschtam there is an easy road down the valley of the Alai, at the upper end of which lies the Kizilart Pass through the Mustagh Tau range. This route, which skirts the Chinese frontier, passing lakes Kara Kul, Rang Rul, and Victoria, is one of the most important in the territory claimed as Russia, and the valley of the Alai can be reached from Marghilan direct by the Tenghis-Bai Pass, and from Samarcand, the railway terminus, up the valley of the Zerafshan.

Generally speaking, the Russian approaches to the Pamir present no especial difficulties in suitable weather; although not at present available for wheeled vehicles, they could doubtless be made so, and the rich provinces of Ferghana and Samarcand could furnish all the supplies which could be transported over them. On the other hand, to make roads adequate for heavy wheeled traffic from Osch Marghilan, and Pendschakent, the present termini of the post-roads, would require a large outlay and considerable time. The state of the Terek-Davan, the main pass into Kashgar, leads to the inference that the other passes, at present used practically only by the Kirghis shepherds, are still less improved, and all these routes are dangerous, if not impassable in bad weather; heavy snowstorms are liable to interrupt the communications for a considerable time

There is a small garrison at the fortified post of Guldscha, but the first Russian town on this road is called Osch. The native place is of considerable antiquity, but the Russian town is brand new, and provided with civilised shops, post-office, telegraph, and other appliances of civilisation. Here I took leave of my guide, the Tartar courier, and rode due west for two days to Marghilan, the Russian capital of the new province of Ferghana, formed out of the old Khanate of Kokan. The inhabitants regard it as a model city, and its wide streets are bordered by avenues of lofty poplars, of such a height that it seems incredible that all this luxuriance is the growth of some fourteen years.

After a week's stay in Marghilan, to rest my horse, I rode to Kokan, also a comparatively new city, but one of the most important trading centres in Central Asia. The activity in its large bazaar and in the caravanserais of the various European forwarding companies, indicate the prosperity to which it might attain were it connected by rail with Samarcand. At present, it costs nearly as much to forward a bale of cotton to Nijni Novgorod by the Trans-Caspian Railway and the Caspian, as to carry it to Orenburg, over 2,000 versts away, by camel caravan, and thence by rail and river.

Tobacco growing would have a great future before it in this country, if the excise regulations were less restrictive. The silk industry has received a good deal of attention of late; and the Government is trying to encourage improved methods of culture, and the introduction of Italian grain to replace the native sorts. But the apathy and ignorance of the Russian trading and agricultural classes wrecks the improvements introduced by intelligent Government officials, whose efforts appear of little avail in view of the low standard of comfort to which the lower class Russian is accustomed, and the absence of incentive to effort, due to the fertility of the land and the exclusion of foreign competition.

From Kokan I rode to Hodschent, and from there to Dschau Boulak, on the Taschkend road. My horse was now nearly worn out, and progress very slow, and, to add to my discomfort, it began to rain. So I disposed of my steed to the Starost (postmaster) at the next station, and completed my journey to Taschkent on wheels, having been 48 days, including stoppages, on the way from Karakol, and ridden nearly 1,000 miles over some of the worst roads in the world.

From Taschkent I travelled to Samarcand, and thence to the Caspian by the well-known Trans-Caspian Railway. Englishmen and Russians have not unnaturally regarded this great work chiefly from a political point of view, and indeed only an actual eye-witness can adequately realise what this great work, the one really new factor in Central Asian existence since the time of Tamerlane, is doing in arousing to new life this people, so long stagnating in isolation and tyranny. The awakening of the Sarts is slow: here, just as in the other alien provinces of the empire is visible the striking inability of the Slav race to impose its civilisation on others except by brute force; but when the present military government of these fertile lands, which at present strangles private initiative by official red-tape, is replaced by the freer conditions of the civil law, and the railroad extends its civilising influence to the other provinces of the State, this dark corner of the earth will commence to take its natural place in relation to the general progress of the world.

DISCUSSION.

Admiral Sir Erasmus Ommanney, C.B., F.R.S., said he had been extremely gratified with this very interesting paper, especially as it referred to a portion of country which had only lately been brought prominently to the public notice. Some parts of the description reminded him somewhat of the coast of Greenland, and he should like to know whether the roads over the tremendous elevations described were at all passable in the winter season, and, indeed if the villages were inhabited at that time of the year. It did not appear as if there had been much cultivation along the route of the Samarkand Railway.

The Rev. Dr. Lansdell said Mr. Jones had been over ground with which he was quite familiar, and he could confirm the accuracy of almost everything which had been said. He was not quite sure whether the eagle, locally called the *berkut*, and used for sporting purposes, was the *Aquila Imperialis*. He obtained in the Musart Pass a very fine specimen, which was now in the Museum of Natural History, South Kensington, where they termed it *Aquila Chrysaëtos*, or Golden Eagle. His impression was that it is the largest kind used for hunting, even such great animals as wolves and small deer. He was very glad to hear the tribute paid to the kindness shown by the Russian officials to English travellers, because there was abroad so much misrepresentation of Russia, so that those who could speak to the contrary ought to do so. Similar testimony had been borne by Mr. Littledale in his paper before the Royal Geographical Society. When he (Dr. Lansdell) was at Tashkent the Governor-General instructed the officials at Osh that if any telegrams came for him they were to be sent on. After passing Kashgar he went round to the Taxin valley, Karghalik, and there he received a letter and telegram which had been sent after him something like 300 miles. When Mr. Littledale was on the Pamir a postcard was sent on more than 100 miles after him. Unless he was greatly mistaken Mr. Jones was the first Englishman who had been over the Tian Shan mountains from Vierney to Kashgar, if not also the first who had gone over the mountains from Kashgar to Osh. Major Cumberland certainly crossed in that direction, but he passed up the Gez defile.

Mr. W. Martin Wood said the paper was so extremely full that there was very little left to say, but there was one incidental question he might ask, viz., the duration of the winter in that region, where Mr. Jones spoke of the melting of the snow in February. It was generally understood that in those regions the summer only extended to three or four months, and that the rest of the year was severe winter weather, and in some parts excessively stormy. The map which had been shown was not quite on as large a scale as those that Lord Salisbury advised people to study; but it was sufficiently large to remind those who examined it that this region was far beyond the frontiers of India, and had no necessary communication with that country; in fact, the intervening portions separated the two countries most effectually. We had, unfortunately, to some extent

ourselves broken down that natural protection, and, as it were, made a way for anyone who wished to come into India to do so; but, it should be remembered, that the regions between those Mr. Jones had described and the frontiers of India, when the impediments and difficulties were considered, were practically hundreds of miles from the Indian border.

Colonel GOURLEY, M.P., said he had listened with much pleasure to this paper. Any information with regard to what the Russians were doing in Central Asia must be very interesting to Englishmen. As a rule, Anglo-Indians endeavoured to create on public opinion an unfavourable impression with regard to what the Russians were doing in that region, and their watchword generally was "wolf, wolf," the idea apparently being that the Russians were coming down like a thief in the night, for the purpose of robbing England of vast territories in India. He was quite certain, however, that whatever ideas might be entertained by some Anglo-Indians, the opinion held by thinking men and men who have visited Central Asia was, that the Russians would have very hard work if they attempted to invade India, not only because of climatic reasons, but also on account of the indomitable courage of our own people, backed, as they would be, by the Indians themselves. His view was that Russia was our neighbour in Asia; we could not help it, and therefore our policy should not be that of the majority of Anglo-Indians, always barking at Russia, and saying we were prepared to fight her, but agreeing with her as to what ought to be the friendly boundaries of the two countries in Central Asia.

Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., said that the Society of Arts were indebted to Mr. Herbert Jones for one of the most interesting papers ever read in their Indian Section. In the impression made by its simple truthfulness it recalled to his mind the late Mr. T. W. Atkinson's work, entitled "Explorations in Oriental and West Siberia," published by his widow in 1857. Mr. Atkinson was an accomplished artist, and gave some graphic illustrations of the *berkut*, or Imperial Eagle of Asia, which was so closely allied to the Golden Eagle that they might be regarded as but local varieties of the same species, and their names as synonymous. What struck the speaker, in looking at Mr. Jones's lantern photographs of the life, labour, and landscape of Central Asia, was the proof they afforded of the great commercial enterprise of the leading nations of antiquity. It was through Central Asia that the civilisation of Nineveh and Babylon were, as Professor De la Couperie has taught us, carried into China; and it was through Central Asia that Greece and Rome received their knowledge of China, until, later on, that country was also reached from the West, by way of the Indian Ocean. Of course it might be that Central Asia, in the process of the centuries, acquired a severer physical aspect and climate, through the gradual elevation of its surface by volcanic force, which Mr. Jones's paper proved was more active there than he, the speaker, had known before. One of the most pleasing features of Mr. Jones's paper was the high terms in which he spoke of the Russian administration, and the Russian officers in Central Asia. Certainly, we Englishmen could raise no objection to Russia occupying any part of Central Asia we did not want for ourselves; and, with this qualification, we should cordially welcome the advance of Russia in Central Asia, as an earnest of the revival of the great prosperity enjoyed by the people of these regions, all through antiquity and the middle ages, down to the conquests of the Mahomedans. He only regretted to find from Mr. Jones's photographs that the Russian type of civilisation so painfully resembled our own. Their public buildings were the very duplicates in thorough-going architectural depravity of those of the Indian Public Works Department; and certainly none of Mr. Jones's photographs gave him greater pleasure than the one representing the complete destruction by an earthquake shock of the Russian high school at Viernay. Were every Government church, high school, and school of art in India reduced to ruin by a similar seismic shudder, he for one would never cease to bless the beneficent discrimination of a congenial and considerate Providence.

Mr. JONES, in reply, said the Kirghis lived on these heights in their *yourts* all through the winter, though no doubt many of the old people died off. With regard to the *berkut*, he did not claim to be an ornithologist, but his information was acquired from a well-known German collector named Reichbeil, who collected for the Berlin Entomological Society, formerly on the Amoor, but was now resident not far from Karakol, and who was almost the only scientific man in that part of the country. At the same time he thought he knew sufficient of the golden eagle to say it was not that bird in the Karakol district. He did not know that they were capable of killing the great Maral stag, which was very rare, but they were perfectly capable of striking down a roe-deer. It was quite possible that his journey by way of the Naryn to Kashgar was the first by an Englishman, but with regard to the south road, it was the route by which most people who had gone to Kashgar in recent times travelled. He had the pleasure of meeting an English traveller, Mr. Beach, who had preceded him on that route when he travelled from Kashgar to Turkestan, and he met him on his return. His remarks with regard to the temperature might be a little misleading, but it depended entirely on the elevation. There was a great difference from that of the steppe, which was a little above the level of the sea, to that of the High Alps. The fact of the snow

disappearing in February was applicable to the Karakol Valley. It seemed to be evaporated by the sun before the end of the winter. On the Naryn they had the temperature of Greenland, and Mr. Reichbeil told him that he had recently discovered there a butterfly, a small colias, whose only other habitat was on the Greenland coast. He found this colias on the high slopes of the Tian Shan in April or May at or above the snow line.

The CHAIRMAN, in proposing a cordial vote of thanks to Mr. Jones, said they had heard a good deal of late about the Russian Chinese frontier, and probably most had read the admirable contributions which Dr. Lansdell had made on that subject. To him the most interesting and welcome part of the paper was the testimony borne to the courtesy and friendliness of the Russian officials. They heard so much in this country against Russia that he agreed with Dr. Lansdell that it was well that the two gentlemen who had been on the confines of the Russian frontier, where there was no Press to take cognisance of what was going on, or to take the part of Englishmen if it was required, should come forward and say how they themselves found the Russian officials to act. He sympathised with the difficulties of Russian civilisation in such a country. They knew how hard it was in India to get Oriental races to take even moderate steps in the path of progress. If, with all the abounding fertility and splendid climate and immense population of India, our task was so difficult, how much more difficult must be that of the Russian pioneers in Central Asia. He agreed with Sir George Birdwood as to the obligation under which the earthquake had placed them with regard to the destruction of the high school; but fortunately it was only the building that was destroyed; the school itself he hoped would go on, in spite of earthquakes, and that Russia in Central Asia, like England in India, would base her progress on a sincere endeavour to educate the people. He felt confident that Russia had a great career before her in Central Asia, as England had before her in India.

The vote of thanks was carried unanimously, and the meeting separated.

APPLIED ART SECTION,

Tuesday, January 26th, 1892; Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., LL.D., M.D., in the chair.

The paper read was by WILLIAM MORRIS, M.A., on "The Woodcuts of Gothic Books."

The paper and discussion will appear in the next number of the *Journal*.

SEVENTH ORDINARY MEETING.

Wednesday, Jan. 27, 1892; R. BRUDENELL CARTER, F.R.C.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Ames, Thomas R. J., 49, Maury-road, Stoke Newington, N.
Browne, Rev. Canon George Forrest, B.D., 54, Bateman-street, Cambridge, and 2, Amen-court, E.C.
Bryden, W. R., 1, George-street, Buxton.
Buchanan, John Young, M.A., F.R.S., 10, Moray-place, Edinburgh.
Chubb, John C., 128, Queen Victoria-street, E.C.
Clarke, Somers, F.S.A., 15, Dean's-yard, Westminster, S.W.
Constable, Archibald, 14, Parliament-street, S.W.
Corder, William, Feeringbury, Westbourne-road, Edgbaston, Birmingham.
FitzGerald, Prof. Maurice Frederick, B.A., Queen's College, Belfast.
Gaymer, John, North Walsham, Norfolk, and John-street Adelphi, W.C.
Gujpatee, Rajah Goday Naraen, Rao, Vizagapatam, India.
Haden, William Nelson, Homefield, Trowbridge.
Halsey, W. S., 213, Cromwell-mansions, S.W.
Hawkins, Herbert Spong, London, Brighton, and South Coast Railway, London-bridge, S.E.
Hughes, John Griffith, Atlantic Engine Works, Bootle.
Kirkaldy, James, 68, East India-road, E.
Ledward, Thomas, 9, Pendrell-road, Brockley, S.E.
Macan, H., M.A., Imperial-buildings, Ludgate-circus, E.C.
Mackenzie, Captain R. J. H. L., R.E., Karachi, India.
Miller, Adam, 11, Queen Victoria-street, E.C.
Oppert, Dr. Gustav, Presidency College, Madras.
Pascoe, James Rogers, Pyrmont, Woodford-green, Essex.
Penfold, Harold, 14, Priory-road, Bedford-park, Chiswick.
Rose, Tom Kirke, 9, Royal Mint, E.
Rowell, Herbert, Hebburn-hall, Hebburn-on-Tyne.
Sibson, Alfred Edward, 2, St. John's-villas, Palmerston-road, Buckhurst-hill, Essex.
Thorp, Walter, B.Sc., The Limes, Henry-road, New Barnet.
Travancore, His Highness Sir Rama Varma, Maharajah of, G.C.S.I., The Palace, Trevandrum, Travancore, India.
Watney, Walter D., 33, Poultry, E.C.
Wilson, Captain Robert Charles Dighton, 21, Chesham-street, Belgrave-square, S.W.
Wilson, Walter H., Queen's-road, Belfast.

The following candidates were balloted for and duly elected members of the Society:—

Braddon, Sir Edward N. C., K.C.M.G., 5, Victoria-street, S.W.
Cowan, Thomas William, 31, Belsize-park-gardens, N.W.
Fitzgerald, Prof. George Francis, M.A., F.R.S., Trinity College, Dublin.
Hotz, A. P. H., Leacroft-house, Staines.
Potter, Walter F., 440, Kingsland-road, N.

The paper read was—

THE SCIENTIFIC VALUE OF LOVIBOND'S TINTOMETER.

By F. W. Edridge-Green, M.D.

From the time that colour first commenced to interest scientific men, a method which would enable us to match colours and keep a record of them for further reference and examination has been desired. The present system of colour nomenclature is unsatisfactory, as in fact all arbitrary systems of colour-naming must be, on account of the varying degrees of colour-perception which are met with in different individuals.

Colour is a sensation, and not an unalterable physical quality of bodies. The same substance may vary in colour according to the conditions under which it is viewed. The rays of light which give rise to the sensation are unalterable, and it is the suppression or admixture of certain of these rays that gives rise to changes in the colour of an object.

The Tintometer is an instrument consisting of two tubes placed side by side on a stand. Both tubes are open at each end. At one end is an eyepiece through which both apertures in the tubes can be viewed. At the ends of the tubes, opposite the eyepiece, is an arrangement for holding the coloured glasses and the substance to be measured. The coloured substance is matched with coloured glasses which are rose, yellow, and blue. The inventor has taken a glass very faintly tinted with each of these colours as a unit, and then constructed a series of glasses in sequence, in accordance with the number of units of the colour in each glass.

The instrument is used as follows:—In the case of transparent substances, a white porcelain plate serves for a background. The porcelain plate scatters white light in all directions, but gives a reflection sufficiently luminous for the purposes of the tintometer. On examining the light reflected from the porcelain plate with a spectroscope, it is found to give a continuous spectrum, the luminosity of the colours being diminished practically in the same degree. It is necessary that the spectroscopic composition of the light reflected from the porcelain plate be known, because a substance may appear white, without reflecting the spectral colours in an equal degree. Two or more of these colours may even be absent from the light reflected by a white substance. This fact may be demonstrated in the following manner:—Let a spectrum be thrown on a screen with the aid of a prism. If a lens be inserted in the course of the rays, so that they will be focussed on the screen, they will be reunited at the point of focus, and again form white light. If an opaque object be interposed, so that one set of coloured rays are cut off, the combination of the remaining rays will form a colour having a hue complementary to that of the intercepted rays. For instance, if the intercepted rays be yellow, the remaining rays will appear blue. If, however, the blue, as well as the yellow rays, be intercepted, the reconstituted beam of light will again appear white. It is evident, therefore, that the removal of one or more pairs of complementary colours from white light will leave the light unaltered with regard to hue, though the luminosity will be correspondingly diminished. A substance, therefore, may be white without reflecting all the rays of the spectrum, provided that equal portions of complementary colours be removed.

In estimating colour there is another point to be taken into consideration, and that is, if a colour be mixed with a large proportion of white light it will not be visible. Captain Abney has shown that the extinction of every colour is effected by white light, which is seventy-five times brighter than the colour. A pale wash of a pigment is not visible on white drawing paper.

When the colours of opaque substances are estimated by the tintometer, the comparison light is obtained from pure plaster of Paris carefully pressed in a small tray.

The coloured glasses used in the tintometer are of three kinds, rose, blue, and yellow. Coloured glass gives rise to its colour through absorption. When a beam of white light falls on a piece of coloured glass, part is absorbed and part is transmitted. On the screen is a spectrum of the blue glass, No. 16 according to the tintometer scale. It will be seen that there are three definite black bands, one in the orange, one in the yellow, and one in the green. These are called absorption bands, and are due to the fact that blue glass absorbs the rays of the spectrum which pre-

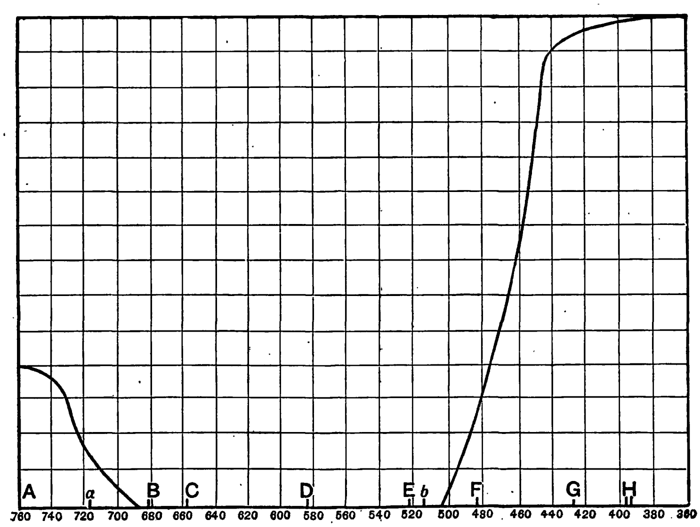
viously occupied the position of the black bands. The absorbed rays are probably converted into some other form of energy.

The colour of coloured glass is therefore a colour which has been produced by subtraction of certain constituents from white light. I showed in the first experiment that if any constituent colour be removed from white light, the residual light will appear of the complementary colour.

I will now draw your attention to the three figures representing the curves of absorption of the three coloured glasses. Absorption diagrams are usually represented by spectra with shaded bands of different depths to represent the absorption bands. It is almost impossible to represent an absorption spectrum in this way when any great degree of accuracy is required. We can more easily represent an absorption spectrum by a curve, the height of the curve corresponding to the degree of absorption. No substance is absolutely transparent to any of the rays of the spectrum. In all cases the absorption is only a question of degree. In the case of the diagrams representing the absorption of light by the tintometer glasses, the absorption by the rose glass is represented to 220° of the tintometer scale, that of the blue glass to 162°, and that of the yellow 207° We could make the curves quite complete by examining an increasing series until the transmitted light was too feeble to affect the eye. A curve constructed in this way would show the exact proportion of the constituents of white light transmitted by a coloured glass.

We have now to consider the cause of the difference in hue and shade of light when allowed to pass through several thicknesses of the same coloured glass, from that which it appears when transmitted through a single piece. If a coloured glass or substance absorbed certain rays of the spectrum, and those only, it would appear of the same colour in a thick layer as in a thin layer, because the thin layer would absorb these rays, and the effect of putting another thickness of glass in the course of the transmitted beams would be *nil*, as it could not affect any of the remaining rays of the spectrum. As I have previously stated, no substance is perfectly transparent to any of the rays of the spectrum, but there are substances which are opaque to certain spectral rays, and almost transparent to the remainder. These substances appear of nearly the same colour in a diluted as in a concentrated solution, in a thick as in a thin layer. Chromate of potash is one of these substances, and it appears very nearly the same colour in a dilute as in a concentrated solution.

FIG. 1.



ABSORPTION CURVE OF THE ROSE GLASS TO 220°.

THE ROSE GLASS.

The glasses of the tintometer therefore produce their colours as follows. Let us first consider the rose glass. If we take the weakest glass and examine it with a spectroscope, we find that the light is transmitted proportionately to the curve in Fig. 1, that is to say, the green is most absorbed, then the

violet, and so on. This glass will then correspond to the apex of the curve, and the resulting colour will be that of light with certain constituents removed in the proportions represented by the curve. Total absorption only takes place at the apex of the curve. It is evident therefore that if we allow the light to pass through two pieces of this glass the second piece of glass can only act on those rays which have passed through the first. As the coloured light absorbed by the second piece of glass is proportional to the heights of the curve, the absorption diagram of both combined may be represented by the curve with a portion of the apex removed. At the point of section there is total absorption. In this way by adding to the number of glasses we pass downwards towards the base of the curve, the sections indicating total absorption becoming larger and larger, and the amount of light transmitted through the glasses smaller and smaller. From this it is evident that a feebly-tinted glass transmits more red light than a glass of a much deeper shade. From the curve it will also be seen that the hue of the transmitted light becomes of a purer red as the number and depth of the glasses are increased, and the violet becomes absorbed.

Rose 22, when examined with the spectroscope, shows a dark absorption band, occupying two-thirds of the green. The violet is partially obstructed. The glass is almost transparent to the remaining rays of the spectrum.

When high combinations are examined, the hue of the transmitted light first changes to orange-red, and then to a pure red.

R. 22+21. Most transparent to red, orange, yellow, and yellow-green; opaque to green and blue green. Transmits blue and violet partially.

R. 22 + 21 + 20. Most transparent to red, orange, yellow, and yellow-green; opaque to green and blue-green. Transmits a few blue and violet rays.

R. 22+21+20 + 19. Transmits red, orange, and yellow partially; opaque to rest of spectrum.

R. 22 + 21 + 20 + 19 + 18 + 19·5 + 18·5. Transmits red and orange partially; opaque to rest of spectrum.

R. 22 + 21 + 20 + 19·5 + 19 + 18-5 + 18 × 17·5 + 17 + 16·5 + 16 + 16·5. Transmits red partially; opaque to rest of spectrum.

It will be noticed in all the diagrams that the absorption bands at the red end of the spectrum, as represented by the curves, occupy positions nearer the centre of the spectrum than they do in the corresponding spectra on the screen. This is due to the fact, that in a spectrum produced by a prism, the colours at the red end occupy less space than they should, having due regard to their wave-lengths. The figures in the diagrams indicate the wave-lengths of the various rays in millionths of a millimetre. The letters indicate the positions of the principal Fraunhofer lines.

The Blue Glass.

This glass is a pure blue in its lighter shades, but the deeper shades incline to violet. In still deeper combinations the hue inclines to reddish violet.

Blue 20 shows a dark absorption band occupying the red-orange, and another in the yellow. The remainder of the orange is nearly absorbed. There is an absorption band of medium depth occupying the central third of the green. The glass is almost transparent to the remaining rays of the spectrum.

In examining the lighter shades of this glass, the absorption bands occupying the red-orange and the yellow are the first to appear. (See Fig. 2, p. 216.)

B. 20 + 19. Almost transparent to band of red, blue, and violet. Transmits yellow-green and blue-green partially; opaque to rest of spectrum.

B. 20 + 19·5 + 19. Almost transparent to band of red, blue, and violet. Transmits blue-green partially; opaque to rest of spectrum.

B. 20 + 19·5 + 19 + 18·5. Transmits a band of red, blue, and violet partially; opaque to rest of spectrum.

B. 20 + 19·5 + 19 + 18·5 + 18 + 17·5 + 17 + 16·5 + 16. Transmits a band of red and violet; opaque to rest of spectrum.

The absorption is always in the same ratio, namely, that shown in the diagram, but as the other colours become absorbed, so do the red and violet rays preponderate, and so the colour becomes reddish-violet.

The great defect in this glass is that it absorbs the green to a very considerable extent. This in a great measure interferes with its utility in combinations.

The Yellow Glass.

This glass in its lighter shades is a pure yellow. Its deeper shades incline to yellow-green.

Yellow 16 absorbs the violet, but is almost

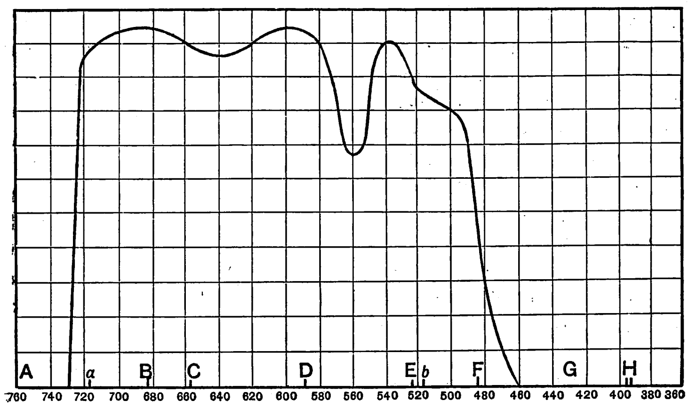
transparent to the blue and the rest of the spectrum. (See Fig 3.)

Y. 16 + 15·5 + 14·5 + 13·5 + 12·5 + 12 + 11·5 + 11 + 10·5 + 10 + 9·8 + 9·6 + 9·4 + 9·2. Most transparent to orange, yellow, and yellow-green; partly transmits green and orange-red; opaque to rest of spectrum.

This glass is one of considerable utility. Though in the deeper shades the yellow-green rays predominate, these are near the yellow, and so do not interfere with the practical usefulness of the colour.

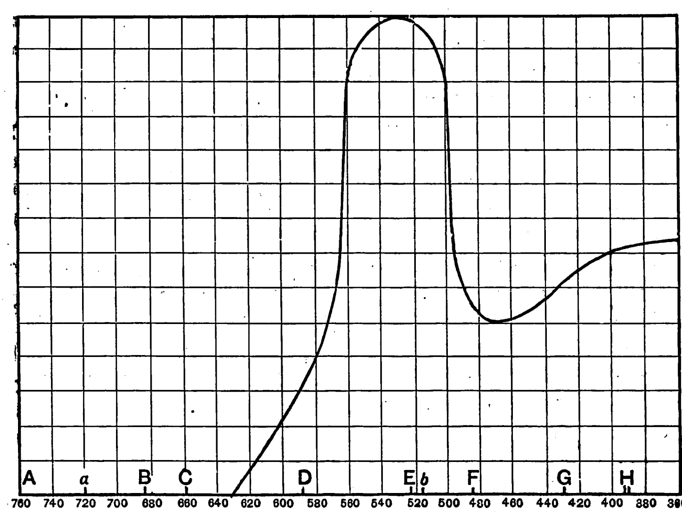
With regard to simple combinations.—B. 16 + Y. 16. = Green. Dark absorption bands are visible in the red-orange and yellow. Absorption band of medium depth in the centre of the green. Very little of the blue and violet can be observed. The yellow-green is seen

FIG. 2.



ABSORPTION CURVE OF THE BLUE GLASS TO 162°.

FIG. 3.



ABSORPTION CURVE OF THE YELLOW GLASS TO 207°.

best. An orange band and the terminal band of red are also seen.

B. 16 + R. 16 = Reddish-Violet. Dark absorption bands in the red-orange, yellow, and central green. The yellow-green is seen best. The remaining rays are partly visible.

R. 16 + Y. 16 = Orange. The blue and violet rays are absorbed. There is an absorption band occupying the central two-thirds of the green. Blue-green rays partly visible. Almost transparent to rest of spectrum.

The spectroscopic composition of any combination may be ascertained by adding together the absorption bands as represented in

the diagrams and deducting the whole from a complete spectrum. Mixture of the remaining rays gives the colour of the combination.

It will be seen that the best glass for the purpose required is the rose, which chiefly affects the green of the spectrum. The worst glass is the blue, as the absorption is not confined to one portion of the spectrum, and a number of green rays are absorbed. From this it will be seen that it is not possible to obtain a very bright green by combining the blue and yellow glasses.

The inventor claims that any colour may be matched with the instrument, and my experience confirms this. Colours, as, for instance, the aniline dyes, which are purer than those produced by the tintometer, may be matched in the following way:—The colour should be matched as nearly as possible with the glasses of the tintometer. When this has been done, the sample colour should be reduced, by adding glasses of the complementary colour to it. For instance, supposing the sample colour is a bright pure green: this should be matched approximately with blue and yellow glasses. Rose glasses should then be added to the colour to be matched, until it is brought within the range of the tintometer colours. It will often be found that the addition of the complementary glass or glasses to any colour will produce not only a change in luminosity, but also an alteration in hue. The reason of this is easy to comprehend. The yellow and blue glasses of the tintometer, when combined, make a green, because the yellow glass absorbs the whole of the violet rays, and so causes the blue to appear green, which is the colour produced by mixing the remaining spectral rays. Now, if this yellow glass be added to a blue, with the intention of reducing its luminosity, it will be found that the blue is not only reduced in luminosity, but that it has also become of a greener hue. This does not directly affect the record, but it does so indirectly, as will be explained shortly. The following example will show how, in practice, these matches are obtained.

A solution of methyl-orange in a $\frac{1}{4}$-inch cell being the colour to be matched. The colour of this was orange. The nearest match in colour was produced by R. 8·2 + Y. 48·5. The solution, however, was very much brighter. An exact match was made as follows:—Methyl-orange solution + B. 3·3 = R. 7·2 + Y. 48·5. It will be seen that when the blue was added one degree less rose was required.

With this and any other colour-matching instrument there is a source of error which has to be carefully considered, and it is due to two factors: (1) that colours appearing exactly alike have not necessarily the same spectroscopic composition; (2) that the spectral composition of daylight varies from day to day, even from hour to hour.

As an instance of a colour varying from these causes, let us consider a solution of chlorophyll which has been matched with a green, which, when examined spectroscopically, does not transmit any of the red rays. A solution of chlorophyll is transparent to a band of red at the end of the spectrum. If this match has been made at a time when the red rays were abundant, as at midday, the two colours would not match later in the day when the red rays were not so abundant. The red rays would be subtracted from one colour and not from the other.

This objection might be overcome if a fixed standard light could be used. I made a series of experiments in order to ascertain what was the effect of this objection in practice. In order that there might be no complication from fading, I obtained a series of coloured glasses, cut to fit the tintometer. The spectroscopic composition of glasses can be easily ascertained. I made a numerous series of experiments with red, orange-yellow, pure green, greenish-blue, light purple and dark purple glasses. I matched these glasses at different times of the day, and on different days. I matched them when the sun was shining, and when it was raining or misty. There was a slight variation in the matches on different days, but not so great as I expected. On days which appeared similar in regard to the character of the light there was no appreciable variation. I think that, for practical purposes, this source of error might be disregarded, care being taken that the examinations are made under as nearly as possible similar conditions of light.

The Value of the Standard.

The inventor has employed for a standard a glass very faintly tinted with colour, and all the other glasses of deeper hue are multiples of this standard. For practical purposes the standard is convenient, and within certain limits gives accurate results. An objection to this method of standardising is that a portion of the spectrum having been absorbed by a glass of a given colour, any glass of a deeper shade of this colour must absorb other rays than those absorbed by the first glass. The

combination of a number of glasses of a given hue therefore does not necessarily give rise to a deeper shade of this hue, but may produce a colour of quite a different hue. This may be admirably illustrated with a solution of chloride of chromium. A thin layer of this solution appears green, but a thick layer appears red. On examining the solutions spectroscopically, the reason of this is evident. A thin layer of chloride of chromium is more transparent to the red rays at the extreme left of the spectrum than to any other part, but the predominance of the green rays causes the colour to appear green. When a thicker layer of the solution is used, the green rays, as well as the rays absorbed by the thin layer, are absorbed, and so the colour appears red. With the tintometer glasses the deeper shades of the blue incline to violet, and the deeper shades of the yellow incline to yellow-green. In each case this is more marked if several glasses be used in combination.

Most persons, on looking at the diagrams of the absorption of light by the coloured glasses, and noticing how irregular the curves are, will wonder how it is that the inventor, with one kind of coloured glass, has been able to obtain a series which has a nearly uniform hue. As I have previously stated, the deeper shades of yellow incline to yellow-green, and the deeper shades of blue incline to violet. The change in hue is scarcely noticeable. The rose glass appears of one definite hue throughout.

This is due to the limitation of our colour perception. A spectrum appears to be made up of six definite colours, which pass by innumerable gradations into each other. Therefore it has been concluded that the number of colours is innumerable. This is an illusion, which is heightened by the knowledge that the colours in the spectrum should be practically innumerable in accordance with the wave lengths of the different rays of light. If we examine the spectrum in another way, all colours but the one under observation being excluded, we find that it is apparently made up of a series of monochromatic bands. These monochromatic bands differ in size according to the acuity of colour perception of the observer. A person with acute colour perception sees differences in a band which appears monochromatic to another person. These monochromatic bands, even for a person with the acutest colour perception, are very large in comparison with the units of the physical series, that is, rays of light of a definite wave-length. Here is a spectroscope which I have had constructed for ascertaining the size of these monochromatic bands. If, for instance, a monochromatic band in the green is being looked at, the observer cannot say on which sides the blue and yellow are situated. These monochromatic bands I have designated absolute psychophysical colour units because they form the units of the psychophysical colour series. As we are now only concerned with colour perception in its bearings on the tintometer, I will refer those who wish to pursue the subject further, to my recently published work on "Colour-Blindness and Colour Perception."* If the hues produced by the mixture of red and violet be added to the spectral series, then all known colours will correspond in hue to some point of this series. If we divide this series according to the number of absolute psychophysical colour units seen by a person with normal colour perception, we see that colours may differ considerably, and yet match perfectly, because both are included in an absolute psychophysical unit. It is evident that if we divided a monochromatic patch into a number of different portions, those portions would all match perfectly, though differing in their physical characters.

This fact makes the instrument of much greater utility than would otherwise be the case. The hue of the glasses practically corresponds to one psychophysical unit throughout the series. Though this fact increases the practical value of the instrument, it militates against its use for the scientific registration of colour, when we wish to record, as nearly as possible, the wave-length of the observed colour.

We have also to consider the influence of the other rays which are transmitted by a glass, upon the colour which the glass appears. With three spectral colours, red, green, and violet, we can match all colours: red and green, when combined, form yellow; green and violet make blue. I have already mentioned the fact that white is formed by the union of the complementaries. Therefore the transmission of rays other than those peculiar to the colour of the transmitted light either intensify this colour, or dilute it with white light.

The instrument is one which would be very useful to those who wish to continually reproduce objects of a given hue, as, for instance, manufacturers of colours. Its value,

* "Colour-Blindness and Colour Perception." International Scientific Series. Kegan Paul, Trench & Co., 1891

from a practical point of view, would be considerably increased if glasses were employed which had, as nearly as possible, the same spectroscopic composition as the substance to be matched. For instance, if a red substance is required in a certain manufacture, and it is necessary to have it always of the same hue, then a series of red glasses, having as nearly as possible the same spectroscopic composition as this substance, should be employed. This will, in a great measure, eliminate the source of error produced by the varying spectroscopic composition of daylight. The instrument might also be considerably improved if it were possible to employ a blue glass which was perfectly transparent to the green rays.

I have employed the instrument to estimate the difference in the perception of colour in the two eyes, and it shows admirably how a colour appearing yellow to one eye, may appear yellow-green to the other.

In conclusion, I am of opinion that the instrument is one which affords everyone who is interested in recording colour for some definite practical object, a simple means of doing so. The colours of glasses have a stability which is not possessed by pigmentary colours. It is obvious that the admirable method of matching colours which has been devised by Captain Abney, and is described in his book on "Colour Measurement and Mixture,"* cannot be generally employed for practical purposes on account of the expense of the apparatus and the knowledge required in using it. The tintometer can be used by anyone who has carefully read the instructions given by the inventor. I thank you for your kind attention, and hope that I have succeeded in showing the range of utility possessed by this instrument.

DISCUSSION.

Mr. LOVIBOND called attention to various diagrams on the walls, illustrating his method of working. He said he had worked with light of much lower intensity than had been used by Dr. Edridge Green, and he was not prepared to say whether the question could be treated on the same lines in the two cases. This first step was to endeavour to get a base line to start from, and he tried to get a normal light, but soon had to abandon that idea, for whether daylight or artificial light were used, they varied so much that there was no possibility of getting a starting point. Then it occurred to him that a line of absorption could be obtained by means of glass standards, to which all lights could be referred, and after many years he succeeded in getting glass in three tolerably pure colours, red, yellow, and blue, which were represented on the diagrams, and then the whole system fell into beautiful order. Each colour cut off the complementary rays as shown, and when they were superposed, the red and yellow, by absorbing each other, developed orange; the yellow and blue, by absorbing each other, developed green; and blue and red developed violet; and thus the six principal colours were obtained. He next found that when the three standard colours were combined in equal proportion, a true visual neutral tint was the result with the light of a dull winter day, but in a clear morning or mid-day they let through the excess of orange and red rays, which he believed preponderated in those lights. In that way he believed he arrived at a normal light, viz., the obscure light of a winter day, which could be gradually absorbed by neutral tint degrees in the three standard glasses; but he recently found that a white sea fog was better, being not only normal to these glasses, but also to the spectroscope, though the latter gave one degree higher readings in all the six colours. Having got the six colours, three in glasses, and three normals, made by combination of pairs of glasses, and also a neutral tint from the three standard glasses, he was able to reduce any light to extinction in regular neutral tint degrees; and by reducing any given light in that way you arrived at its base colour, namely, those colour rays which were in excess over the normal light. Sunlight gave red and orange; the blue sky a considerable amount of blue. A curious fact was, that the effect of the glasses on the spectroscopic colours was not the same as when applied to the same rays when mixed as in ordinary daylight; and he believed that in daylight there was a sort of combination of rays analogous to chemical combination which produced a different effect. There was a considerable difference in the power of various colours to withstand a definite quantity of normal light. Taking these six colours in uniform degrees, he was able to make the characters which were exhibited, showing the whole colours of the spectrum divided into two classes, the first red, yellow, and blue, which he called dominants, or standards, being represented by the standard glasses; the others he called "normals," resulting from combinations. Having described the mode of matching and charting colours less pure, as pure, and more pure than the standards, in which latter case he reduced the colour by a neutral tint, not by adding a complementary colour, as Dr. Green described, he said the purity of any colour varied with the light and the substance, and unless there were some fixed light as a standard of comparison, he did not see how the difficulty could be got over. Some of the designs, giving the results of particular experiments, were then described, and illustrated by quantitative sectional areas, showing in their respective colours the proportion of colour-rays of absorbed and unabsorbed light, which together make

---

* "Colour Measurement and Mixture," by Captain W. de W. Abney, F.R.S., published by the Society for Promoting Christian Knowledge, Northumberland-avenue, W.C.

up the whole beam reflected from various substances, as, for instance, two ultramarines, one pure, the other artificial; different shades of black and white; the exact colour of the various London daily papers; and the colour of various samples of water. Distilled water contained only a little green and yellow; from a chalk well, yellow, green, and blue, and, on filtering, it lost green and blue, and became yellow. Water from the river Aire was nearly black. With reference to the apparent failure of the glasses to do their duty in cutting out the complementary colours in the spectrum, as they did in daylight, when the rays were brought together in daylight, he believed they combined and acted differently on the glass to what they did when they were taken separately, as in the spectrum. This could be shown by building up white light with isolated coloured rays; that is, with colour rays entirely separated from the excess of light, and overlapping adjacent rays in the crowded end of the spectrum, which appear to be inseparable in experiments made with the spectrum produced by the prismatic spectroscope.

Mr. SEBASTIAN DAVIS said there was a peculiar tint found in water which had been treated by Clark's process, in which a quantity of lime was added to remove the carbonic anhydride, and then precipitated. After that a peculiar blue tint was obtained. This could be well seen at Joynson's Paper Mills, at Dartford, where the system was used. Perhaps Mr. Lovibond could explain how that arose.

Mr. LOVIBOND said he had not experimented on that water.

Captain ABNEY said Mr. Lovibond had perfected this admirable instrument in a manner which not only reflected the greatest credit on him, but showed the scientific character of his mind, though, as he understood, he had not had a scientific training. It was quite true he believed, as stated in the paper, that if you had two or three glasses together you could tell the character of the light by deducting the absorption of each glass from white light, and mixing the remainder; but in order to do that, it was necessary on this plan, that each individual glass should be measured, which would be a work of no small labour. Mr. Lovibond had taken as his standard the minumum colour, and his contention was that for scientific purposes it was rather the maximum which ought to be standardised—for this reason. If you put twelve No. 16 glasses together, though he was quite sure they would not differ appreciably, and if you had the total absorption, you could easily calculate that of each one; but when you came to take the absorption spectrum of a faint colour, the errors you might make were so enormous that, when multiplied by twelve, they would make the readings untrustworthy. A great many yellow glasses together gave orange, and from several blue glasses you got a very different colour from that of a light-tinted glass. On what system, therefore, was it suggested that the absorption spectrum should be deducted from white light so as to get a scientific measurement of colours? Dr. Edridge-Green said two colours which differed considerably in wave length might yet match perfectly, because they were both included in one psychophysical unit. It might be a matter of opinion or of experiment, but he certainly could not accept that statement, which seemed to him erroneous because he personally could distinguish any slight variation in the colour of the spectrum which lay, he thought, well within the physophysical unit as defined. He could see plainly that one part of the green patch shown on the screen was yellower than the other. With the instrument which he had shown there on more than one occasion, the minutest difference in the position of the slit placed in the spectrum could be detected. If you could divide the spectrum into 100 parts you could tell each one from the other. In looking at a rather impure spectrum, at first glance, he only saw three colours—red, green, and violet; and when he came to examine it, he found an infinity of colours. He therefore could not endorse the statement that you could not distinguish one colour from another if they were situated close together, and his opinion was founded on experiments which numbered thousands, and had been going on many years. As to the glasses, he had already said that this instrument was very valuable, but he could not sanction Mr. Lovibond's heresy that there was any combination of rays in one kind of light more than in another. The great thing to aim at was to have a material perfectly free from banded absorption, which for scientific purposes was a great drawback. The blue glass appeared to be cobalt, but there were other blues which were free from those bands of absorption in the red end; and for scientific purposes it would be preferable to use a glass having general absorption rather than one with a banded absorption. The normal light from white fog was very interesting. The search for a normal or standard light had gone on for some years, but for his own purposes, and for scientific work, he found nothing to equal the crater of the positive pole or the electric arc. It was always a uniform temperature, and was always equally white, which could be proved thus:—Take a shortish spectrum, and put in two slits, one in the green, and the other in the violet; mix the two lights together in such proportion as to form white, and you might watch alongside of it the white light undecomposed. Put any carbons you liked into the lamp, there would be no variation, showing that the proportion of green to violet was the same in both. To that standard all lights and all colours might be referred. He was surprised to hear that distilled water was yellow and green. A few years ago, he investigated the absorption spectra of colourless fluids in the ultra red by means of photography, which had no personal bias, and registered its own results, so that there could be no mistake, and distilled water he found anything but yellow. He had a tube 6 feet long,

and no ultra red light passed, very little red, slight yellow, and plenty of blue; so that distilled water in its purest form certainly had a blue tint. He did not throw any doubt on Mr. Lovibond's observations, but on the purity of the water he used. The water from the gravel well seemed to bear out the conclusion that pure water would be a blue colour.

Mr. LOVIBOND said there might be impurities in the standard glasses. Even supposing that the impurities were not self-correcting, he did not think they could be so great as to create the difference between the two sets of observatious. The water he used was carefully distilled from glass, but you could make such water look any colour you liked, by illuminating it with light of that colour. If you looked at it with light from a blue sky, you had a beautiful blue colour, while, in the morning's light, you get a reddish tinge; in fact, the visual colour changed with the light, whilst the measured colour remained constant. There was always a danger of mixing up the measurement of the object with the light it was viewed by. That was why he did not like to rely on measurements made by intense light. No definite statements of visual impressions could be made unless the light employed was quoted.

Dr. THORNE said he had used this instrument for some time in his laboratory for estimating the colours of oils, glass, and so on, and found it very useful for registration and comparison. It gave results which were not to be obtained by any of the easily utilisable forms of colorimeters. From a scientific point of view, as Captain Abney had said, an intense colour would be the best unit, but for ordinary purposes it was necessary to deal almost entirely with low tint colours.

Dr. EDRIDGE-GREEN, in reply, said Captain Abney had answered the objection raised by Mr. Lovibond with regard to the light, and he need only add that it was desirable to choose lights as nearly as possible of the same character. The method he had described, of measuring the absorption curve, was the same as that employed by Captain Abney. For the yellow, he took about twenty-two glasses, which gave the highest point, 207°. One could go on adding glasses until all the light was excluded, and thus get a complete curve. It would be very difficult to measure with the spectroscope faintly tinted glasses. With regard to the psychophysical units, the patch on the screen was only approximately monochromatic, but in looking at a pure spectrum, he could see a very large portion which appeared absolutely monochromatic, as did the patches Captain Abney had showed him, which contained a large number of wave lengths. He had not succeeded in seeing any more colours in a magnified spectrum than in one produced by a good spectroscope. He therefore ascribed this limitation to a limitation in perception, and he found this to differ in different persons. Some could see very minute deficiences, but even then they saw a unit which corresponded to a large number of wave lengths.

Captain ABNEY said with his instrument you could make the slit as fine as you liked, for instance, as the difference between the two D lines. The spectrum could be made as pure as you liked by closing first the slit of the collinator, and, secondly, the slit in the spectroscope. If you had a spectrum of 5-in. length, and made the slit ·01 in., it would not be difficult to calculate within what difference of wave length you got a different colour.

Dr. EDRIDGE-GREEN asked if Captain Abney could distinguish a difference of colour between the two D lines. To him they were absolutely monochromatic.

Captain ABNEY said the only way to compare two colours was to put them side by side in a patch, and he had never done that with the light of the two D lines. You might call a line any colour you liked almost when dim; there must be a certain area, or you could not distinguish it. You would not see any yellow in the sky through a pocket spectroscope, because your vision was confined, but directly you took a large spectroscope and pointed it in the same direction, the yellow appeared. It was a question of size as much as anything else.

Dr. EDRIDGE-GREEN admitted that entirely, but said different persons had different perceptive powers, one would see yellow where another would not. In the case mentioned where the yellow was not seen, the observer was reduced to a condition of imperfect perception; in other words, he saw as if he were partially colour-blind. Orange was the first to go; then blue then yellow, then green. He did not think a normal-sighted person could succeed in reducing his perception below the three primary points of difference—red, violet and green; but by reducing the light you could cause yellow, or blue, or orange to disappear. However you magnified the spectrum, you saw no more colours, and no less. With defective light you might see five, four, or three, instead of six. He had never succeeded in seeing the seven which Newton described; but there were a few persons who did, and they described them exactly as Newton did. It was only in that sense he used the term psycho-physical units.

The CHAIRMAN, in proposing a vote of thanks to Dr. Edridge-Green, said the deep blue colour of water treated by Clark's process could be very well seen near Caterham, in the tanks of a local water company, where this process was adopted. It had always appeared to him to be analogous to the blue of the sky, and to be due to the same cause, namely, the presence of very fine particles, arising from the precipitation process, which had not sunk to the bottom.

The vote of thanks was carried unanimously, and the proceedings terminated.

Miscellaneous.

FOREIGN COUNTRIES AT THE CHICAGO EXHIBITION.

A memorandum lately issued by the Chicago Executive gives the following list of foreign countries which have accepted, with the amounts voted, where these are known:—

	Dollars.		Dollars.
Argentine Republic	100,000	Great Britain—	
Austria	149,100	Trinidad	15,000
Belgium		Victoria	
Bolivia	100,000	West Australia	
Brazil	600,000	Guatemala	120,000
China		Hawaii	
Chili	100,000	Hayti	
Colombia	100,000	Honduras	20,000
Costa Rica	100,000	Italy (informal)	
Denmark		Erythria	
Danish West Indies		Japan	630,760
Ecuador	125,000	Korea	
Egypt (informal)		Madagascar	
France	400,000	Mexico	750,000
Algeria		Netherlands (informal)	
Germany	215,200	Dutch Guiana	10,000
Great Britain	125,000	Dutch West Indies	5,000
Barbadoes	6,000	Nicaragua	30,000
British Columbia		Orange Free State	
British Guiana	25,000	Paraguay	25,000
British Honduras	7,500	Persia	
Cape Colony	25,000	Peru	125,000
Ceylon	40,000	Russia	
India		Salvador	12,000
Jamaica	20,000	San Domingo	
Malta		Siam	
Mashonaland		Spain	
New South Wales		Cuba	25,000
New Zealand		Transvaal	
Queensland		Turkey	
South Australia		Uruguay	
Tasmania		Venezuela	
		Total	$4,004,560
		or say	£800,000

Herr Wermuth, the German Imperial Commissioner to the Exposition, has sent word that the 100,000 square feet reserved for Germany in the Manufactures Building has already been taken, and that much more space could be utilised by German manufacturers if it can be obtained.

A Reuter's telegram states that Mr. Davis, the Director-General of the Exposition, has received from M. Antonin Proust, Director of the Fine Arts Section of the World's Fair Commission of France, an application for 82,000 square feet of wall space in the Art Building, and this amount, large as it is, will probably be granted. England and Germany have each asked for, and been allotted, 20,000 square feet (of floor space, probably equivalent to 25,000 square feet of wall space), while Belgium has secured 8,000, Holland and Denmark 3,000 each, and Japan 2,000 square feet. According to the architect who designed the structure, the Art Building and annexes will contain 250,000 square feet of floor and a mile of wall space, so that it will doubtless be found possible to meet all demands.

NUTMEG CULTIVATION IN JAMAICA.

In the *Bulletin of the Botanical Department of Jamaica* for October last it is stated that a large stock of the very finest nutmegs for seed has been imported to Jamaica from Grenada, and has been sown in the Hope Gardens, and, when ready for distribution, will be sold at the very low rate of three halfpence each, in large or small quantities. It is hoped that these arrangements will tend to develop the planting of nutmegs on a large scale in suitable districts in Jamaica. It is stated that already one order has been filed for 10,000 plants, and another for 5,000. The germination of the seed in large quantities, and the care of the seedlings, is said to require the strictest attention, to prevent extensive loss. From the seed beds, the seedlings are transferred to bamboo pots, and, when they have quite recovered from the transplanting, and have formed good roots, they are ready for the nutmeg plantation. The planters must now exercise strict supervision over the labourers, to see that the bamboo pot is carefully slit down on one side, and the plant, with the earth undisturbed round the root, gently placed in the hole prepared for its reception. If this operation is done too harshly or clumsily, the tip of the tap root is broken, and the plant soon dies.

Nutmeg trees require a deep, rich, loamy soil, moist, but not swampy, with a humid atmosphere. They thrive best in steady river valleys from sea-level up to 300 or 400 feet, but they will grow in favourable situations up to an elevation of 2,000 feet. The trees should be placed at distances of 25 or 30 feet apart, and if the situation is not naturally shady and sheltered, trees should be planted for the purpose of breaking the wind as well as for shade. The trees are a long time coming to maturity, not producing a crop, as a rule, till they are nine years old; and only when they first flower, at six or seven years of age, is it possible to determine whether they are male or female. A very small proportion of male trees is left for fertilisation by insects; the rest are cut down, and fresh plants are substituted. The fertile trees continue to produce fruit for seventy or eighty years. On an average, each tree will yield ten pounds of nutmegs and about one pound of mace every year, and, when highly manured, it is said that they will produce ten times that amount.

In connection with the same subject, a note on the curing of nutmegs in Grenada is given in the November number of the *Jamaica Bulletin*, the details of which may be of service to those who are starting the culture. The process is said to be that which is adopted for preparing the nutmegs for the London market. The nutmegs are picked up from under the trees every day, except Sunday. On being brought into the boucan, the mace is peeled off and pressed flat between heavy blocks of wood, where it is left for two or three days, then put into a case and left, till it reaches the proper colour. The nutmegs are put into receptacles (with fine mesh bottoms, so that the air can pass through) inside the boucan, and left there for three weeks or a month, in fact until the nut begins to shake inside the shell. They are then shown the sun for a couple of hours a day for two or three days. After this they are cracked. Great care is necessary here, for if the outside shell is struck too hard it makes a black spot in the nutmeg, which affects the value considerably. When cracked the nuts are sorted according to size, put into ordinary flour barrels and shipped. Regarding the value of the produce of nutmeg trees, when in full bearing, it is stated that one grower in 1883 realised from two trees as much as £30.

Obituary.

DR. ALFRED CARPENTER.—Dr. Carpenter, an active member of the Society since 1876, has just died at Ventnor. He was born in 1825, educated at Moulton Grammar School, Lincolnshire, and studied medicine first at Northampton Infirmary, and afterwards at St. Thomas's Hospital. He commenced practice at Croydon in 1852, and was a particularly energetic member of the Croydon Board of Health. He was elected President of the Council of the British Medical Association in 1879, and was for many years a Justice of the Peace for Surrey. Dr. Carpenter read several papers before the Society of Arts, and was a frequent attendant and speaker at meetings on sanitary subjects. The last paper read by Dr. Carpenter before the Society was on the "Utilisation of Town Sewage by Irrigation," on February 2nd, 1887.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock :—

FEBRUARY 3. — T. PRIDGIN TEALE, M.A., F.R.C.S., F.R.S., "Dust, and How to Shut it Out." Prof. T. E. THORPE, Ph.D. F.R.S., will preside.

FEBRUARY 10.—E. PRICE EDWARDS, "Burning Oils for Lighthouses and Lightships." Sir LYON PLAYFAIR, K.C.B., F.R.S., will preside.

FEBRUARY 17.—Capt. F. E. YOUNGHUSBAND, "The Pamirs."

FEBRUARY 24.—Mr. ERNEST HART, "Ancient and Modern Art Pottery of Japan." Prof. WILLIAM ANDERSON, F.R.C.S., will preside.

MARCH 2.—Prof. VIVIAN B. LEWES, "Spontaneous Ignition of Coal, and its Prevention."

MARCH 9.—A. P. LAURIE, M.A., "Experiments on the Durability of Modern Pigments."

MARCH 16.—TEMPEST ANDERSON, M.D., "Iceland."

MARCH 23.—GILBERT R. REDGRAVE, "Manufacture and Industrial Application of Flexible Tubing."

Papers, the dates of reading of which are not yet fixed :—

"The Fisheries Department: its Position and Prospects." By J. W. WILLIS BUND.

"The Congo State." By Captain V. LOVETT CAMERON, R.N., C.B.

"Colour Blindness." By Captain W. de W. ABNEY, C.B., F.R.S.

FOREIGN AND COLONIAL SECTION.

Tuesdays, at Half-past Four or Eight o'clock; due notice of the hour will be given :—

FEBRUARY 16.—LEWIS ATKINSON, "The Forthcoming Exhibition at Kimberley." 8 p.m. The paper will be illustrated by lantern slides.

MARCH 15.—F. A. PEZET (Peruvian Consul General), "Peru." 8 p.m.

APRIL 5.—The Rev. JOHN MCLEAN, D.D. "Manitoba and the North-West Provinces of the Dominion."

APRIL 26.—Sir EDWARD BRADDON, K.C.M.G., "The Progress of Australasia."

MAY 24.—Colonel HOWARD VINCENT, C.B., M.P., "The Extension of Colonial Trade."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m. :—

FEBRUARY 11.—LORD LAMINGTON, "Recent Travels in Indo-China." Lieut.-General Sir ANDREW CLARKE, G.C.M.G., C.B., C.I.E., will preside.

MARCH 3.—Surgeon-General Sir WILLIAM JAMES MOORE, K.C.I.E., "Indian Sanitation and the International Congress of Hygiene." Major-Gen. Sir OWEN TUDOR BURNE, K.C.S.I., C.I.E., will preside.

MARCH 24.—G. H. M. BATTEN, formerly of the Bengal Civil Service, "The Opium Question." Sir JOHN STRACHEY, G.C.S.I., C.I.E., will preside.

APRIL 7.—Dr. J. AUGUSTUS VOELCKER, "The Agricultural Needs of India."

APRIL 28.—Sir WILLIAM WEDDERBURN, Bart., "Reorganisation of Agricultural Credit in India." The Right Hon. Sir JAMES CAIRD, K.C.B., will preside.

MAY 19. — JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock :—

FEBRUARY 23.—J. WILLIAM TONKS, "Artistic Treatment of Jewellery: Jewel and Address Caskets." Sir PHILIP CUNLIFFE-OWEN, K.C.B., K.C.M.G., C.I.E., will preside.

MARCH 29.—E. ROSCOE MULLINS, "The Decorative Uses of Sculpture." ALFRED GILBERT, A.R.A., will preside.

APRIL 12. — C. PURDON CLARKE, C.I.E., "English Brocades and Figured Silks."

MAY 17.—GEORGE J. ROBINSON, "Decorative Plaster Work" (II.). J. HUNGERFORD POLLEN will preside.

CANTOR LECTURES.

Monday evenings, at Eight o'clock :—

PROF. GEORGE FORBES, F.R.S., "Developments of Electrical Distribution." Four Lectures.

LECTURE II. — FEBRUARY 1. — High-pressure supply—Old attempts—Alternate currents—Transformers — Feeders — Sub-stations — Overhead and underground conductors—Generation of electricity by power obtained at a distance from (1) electricity, (2) gas, (3) compressed air, (4) water under pressure—Load factor—Waste products.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 1 ... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Prof. George Forbes, "Developments of Electrical Distribution." (Lecture II.)

Farmer's Club, Salisbury-square Hotel, Fleet-street, E.C., 4 p.m. Mr. Rew, "The Migration of Farm Labourers to the Towns."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Westminster Town Hall, 7½ p.m. Inaugural Address by the President (Mr. J. W. Wilson, jun.)

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Messrs. Wanklyn and Johnstone, "Oxidation of the Fatty Acids." 2. Mr. Watson Smith, "The Stability of Certain Organic Nitrogen Compounds occuring in Coal-Tar Pitch."

Surveyors, 12, Great George-street, S.W., 8 p.m. Discussion on the paper by Mr. E. H. Morris, "The Four-Course System, with Desirable Variations."

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 1 A, Adelphi-terrace, W.C., 8 p.m. 1. Mr. J. W. Slater, "Natural Selection." 2. Mr. J. J. Murphy, "Reality of Knowledge." 3. Capt. F. Petrie, "Brief Notes on a recent Submarine Volcano."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Louis Fagan, "Line Engraving—English School."

TUESDAY, FEB. 2 ... Royal Institution, Albemarle-street, W., 3 p.m. Professor Victor Horsley, "The Brain." (Lecture III.)

Central Chamber of Agriculture (at the HOUSE OF THE SOCIETY OF ARTS), 11 a.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Alfred Harper Curtis, "Gold-Quartz Reduction."

Pathological, 20, Hanover-square, W., 8½ p.m.

Biblical Archæology, 9, Conduit-street, W., 8 p.m.

Zoological, 3, Hanover-square, W, 8½ p.m.

WEDNESDAY, FEB. 3 ... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. T. Pridgin Teale, "Dust, and How to Shut it Out."

Entomological, 11, Chandos-street, W., 7 p.m.

Archælogical Association, 32, Sackville-street, W., 8 p.m.

Obstetrical, 20, Hanover-square, W. 8 p.m. Annual Meeting.

Civil and Mechanical Engineers, Westminster-palace Hotel, S.W., 7 p.m. Mr. J. F. Reade, "Main Drainage Extension in Towns."

Electrical Engineers, in the Theatre of the Royal Institution, Albemarle-street, W., 8 p.m. Mr. Nikola Tesla, "Experiments with Alternate Current of High Potential and High Frequency."

THURSDAY, FEB. 4...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. F. N. Williams, "A Monograph of the Dianthus." 2. Dr. G. Jeunings Hinde and Mr. W. Murton Holmes, "The Sponge Remains in the Lower Tertiary Strata, near Oamaru, Otago, New Zealand."

Chemical, Burlington-house, W., 8 p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. Percy Fitzgerald, "Recollections of Charles Dickens."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. S. Murray, "Some Aspects of Greek Sculpture in Relief." (Lecture III.)

Historical, 11, Chandos-street, W., 8½ p.m. Mr. O. Browning, "The Evolution of the Family."

Mechanical Engineers, 25, Great George-street, S.W., 7½ p.m. Mr. Joseph Parry, "Notes on Mechanical Features of the Liverpool Water Works, and on the supply of Power by Pressure from the Public Mains, and by other means."

Archæological Institution, Oxford-mansion, Oxford-street, W., 4 p.m.

FRIDAY, FEB. 5...United Service Institution, Whitehall-yard, 3 p.m. Lieut. H. B. Jones, "Military Ballooning."

Royal Institution, Albemarle-street, W.. 8 p.m. Weekly Meeting, 9 p.m. Prof. W. C. Roberts-Austen, "Metals at High Temperature."

Mechanical Engineers, 25, Great George-street, S.W., 7½ p.m. Mr. William Hawdon, "The Disposal and Utilisation of Blast-Furnace Slag."

Geologists' Association, University College, W.C., 8 p.m. Address by the President, "The Evolution and Classification of the Cephalopoda: an account of recent advances."

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Physical, Science Schools, South Kensington, S.W., 5 p.m. 1. Prof. G. F. FitzGerald, "The Driving of Electro-Magnetic Vibrations by Electro-Magnetic and Electro-Static Engines." 2. Prof. S. P. Thompson, "Supplementary Colours."

SATURDAY, FEB. 6...Royal Institution, Albemarle-street, W., 3 p.m. Professor J. A. Fleming, "The Induction Coil and Alternate Current Transformer." (Lecture III.)

Saturday Lecture Society, Lecture Theatre, South Kensington Museum, S.W., 3 p.m. Capt. W. de W. Abney, "Colour Blindness."

Journal of the Society of Arts.

No. 2,046. Vol. XL.

FRIDAY, FEBRUARY 5, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CANTOR LECTURES.

The second lecture of the course, on "Developments of Electrical Distribution," was delivered by Prof. George Forbes, F.R.S., on Monday evening, 1st inst. The lectures will be printed in the *Journal* during the summer recess.

APPLIED ART SECTION.

The publication of Mr. William Morris's paper, on "The Woodcuts of Gothic Books," is unavoidably postponed until next week, when it will be printed in the *Journal.*

Chicago Exhibition, 1893.

A meeting of the Royal Commission was held on Wednesday, 3rd inst. Present: The Attorney-General, M.P., in the chair; Sir Frederick Abel, K.C.B., D.C.L., F.R.S., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Sir Frederick Bramwell, Bart., D.C.L., F.R.S., Sir Owen Tudor Burne, K.C.S.I., C.I.E., Michael Carteighe, Francis Cobb, Prof. James Dewar, M.A., F.R.S., Major-Gen. J. F. D. Donnelly, C.B., James Dredge, Sir Douglas Galton, K.C.B., D.C.L., F.R.S., C. Malcom Kennedy, C.B., Alexander B. W. Kennedy, F.R.S., John Biddulph Martin, J. F. Moulton, Q.C., F.R.S., W. H. Preece, F.R.S., Prof. W. C. Roberts-Austen, C.B., with Sir Henry Trueman Wood as Secretary.

COMMITTEE ON AGRICULTURE.

A meeting of the Agriculture and Food Products Committee was held on Monday, 1st inst., at 12, Hanover-square. Present: The Earl of Feversham, President of the Royal Agricultural Society, in the chair; Earl Cathcart, G. Allender, Sir Edward Birkbeck, Bart., M.P., J. Bowen-Jones, W. Burdett-Coutts, M.P., Alfred Darby, Colonel Sir Nigel Kingscote, Lieut.-General Michael, C.S.I., Ralph Palmer, Albert Pell, Daniel Pidgeon, John Thornton, Dr. J. A. Voelcker, Sir William Williams, Christopher W. Wilson, with Sir Henry Trueman Wood, Secretary of the Royal Commission, and Ernest Clarke (Honorary Secretary).

COMMISSION FOR NEW SOUTH WALES.

The New South Wales Government has appointed a Commission for the Chicago Exhibition, of which Mr. William McMillan is President, and Dr. A. Renwick, Executive Commissioner. It is estimated that the cost of the Commission will be £30,000.

REPORT ON THE PRESENT CONDITION AND PROSPECTS OF THE CHICAGO EXHIBITION.

By Colonel J. Hayes Sadler,
H.M. Consul at Chicago.

The following Report (dated 13th January) on the progress made in the constructions and arrangements for the World's Columbian Exposition, to be held at Chicago in 1893, has been received by the Secretary of the Royal Commission from the Secretary of State for Foreign Affairs :—

Introduction.

Anyone who now visits the site of the proposed Chicago Exhibition, and saw its condition when first ground was broken on the 27th January last year, must marvel at the progress which has been made in this vast undertaking, and at the rapidity with which the plans have taken shape. No reasonable doubt can now be entertained that the constructions and arrangements on the ground will be completed, and that everything will be ready within the required time. But it is not only in Jackson-park that great progress has been made. The organisation of the executive machinery, and preliminary plans and

arrangements, which entailed a vast amount of labour, are complete, and working well and smoothly; and it may be fairly said that all the necessary details have been decided or considered; that such matters as may further arise are ready to be met; and that the preparations for the largest Exhibition ever held are perfected. The energy and determination, the liberality and fairness shown in the management of the enterprise, both by the National Direction and the Local Commission, are proofs of the executive talent selected to preside over the different departments, on which such an enormous amount of work has been thrown.

The progress made in the constructions and arrangements will be seen under the following heads :—

1. Introduction.
2. The Site.
3. Financial position.
4. The Main Buildings.
5. Cost and progress of Exposition Buildings.
6. Other Works.
7. Government and State Buildings.
8. Foreign Countries.
9. Transportation.
10. Insurance.
11. General Regulations.
12. World's Congress Auxiliary.
13. Other attractions.
14. Prospects and advantages of exhibits.
15. Dedication and Opening.

The Site.

When first this city was selected for the World's Columbian Exposition, the difficulties to be encountered by the Chicago Commission were great and numerous; the fixing on the site, which was a peculiarly embarassing matter, was the subject of long discussions; many conflicting opinions and interests were brought to bear before a decision could be arrived at; but the one broad view of consulting solely the interest of the Exhibition was adhered to, and there appears to be no other opinion than that no better site could be chosen than the one selected, and it is generally admitted to be perfect. Situated for the length of a mile and a half on the borders of Lake Michigan, which has all the appearance of a sea, Jackson-park, though seven miles from the centre of the city, affords the great advantage of space; it has an area of 586 acres, besides which there are the 80 acres of the Midway Plaisance, an unoccupied piece of ground adjoining it on the west and leading to the neighbouring South-park, which affords a further space, if necessary, of 371 acres. It affords another great advantage over all former Exhibitions of a similar character, that of water.

With the exception of a small portion on the northern side, the whole of Jackson-park a year ago was a swamp, a combination of marsh, water, and hummocks, and a vast amount of labour, time, and expense was required in laying out the ground preparatory to the foundations being laid of the proposed buildings. The borders of the lake have already been converted from a sandy beach into a stope of stonework, capped by a magnificent esplanade of white concrete; the grounds are laid out in broad terraces, basins, lagoons, and canals, separating and in great part surrounding many of the principal buildings now in course of construction, and as soon as these buildings are finished plans are ready for finally beautifying the grounds, and setting out beds of flowers. Many trees have been already planted, and several thousand plants are in the propagating houses. The buildings are of great size and architectural beauty, and with the distribution of water, the grounds will provide a scene of unequalled beauty.

Financial Position.

Cost.—The cost of the buildings constructed by the World's Fair Commission, which do not include such as may be built by the United States Government, the various States of the Union and foreign countries, or other constructions for which concessions may be granted, will amount to about £1,600,000,* and besides this sum there are other sums estimated as follows :—

	£
Grading, filling, &c.	90,080
Landscape gardening	64,680
Viaducts and bridges	25,000
Piers	14,000
Waterway improvements	45,000
Railways	100,000
Steam plant	160,000
Electricity	300,000
Statuary on buildings	20,000
Vases, lamps, and posts	10,000
Seating	1,600
Water supply, sewerage, &c	120,000
Improvement of lake front	40,000
World's congress auxiliary	40,000

* For the convenience of this Report, exchange is calculated at the rate of 5 dollars per £1 sterling.

	£
Construction department, expenses, fuel, &c.	104,000
Organisation and administration	661,713
Operating expenses during Exposition	310,000
	£2,106,091

Making a total of £3,706,091, as the cost of the Commission, to meet which the following is a statement of resources:—

	£
Stock subscriptions	1,144,246
City of Chicago bonds	1,000,000
Prospective gate receipts	2,000,000
Concessions and privileges	300,000
Salvage	6,600
	4,750,846
To which may be added future subscriptions and interest on deposits estimated at	40,000
Total..	£4,790,846

As the gate receipts will not come in till the Exhibition is open, and payments on the contracts must be met, it is proposed to ask a loan of £1,000,000 from the United States Government, which it is believed will be shortly laid before Congress. The charge on entrance to the grounds will probably be fixed at two shillings.

The Main Buildings.

The great buildings, constructed at the charge of the Commission, are distributed in the centre and southern part of the park, the northern part of which is set aside for the constructions of foreign countries and the separate States of the Union. They cover 153·8 acres, and, with the gallery area, will have a total floor space of 199·7 acres. The most eminent architects in the country have contributed to the plans, and every endeavour has been made that the enterprise shall have a thoroughly national, and not solely a local, character. The architecture is greatly Corinthian, and promises, in an artistic point of view, to be eminently successful; at the same time the lagoons and canals will give a Venetian effect, and reflecting the numerous palaces and the powerful electric lights will produce a magical appearance at night. The framework of the Exposition buildings, which are designed for temporary use and for removal, is of iron or steel sheathed with wood, and coated inside and outside with staff. This latter material is composed of clay, plaster of Paris, glue and hair, and is fire-proof and impervious to water. It is moulded in sheets, of various and elaborate designs, and affixed to the wooden sheathing; tinted in imitation of different stone and marble, it gives all the effect of sculptured masonry. The masonry of the lagoons and statuary will also be of this material. The advance made of late at Chicago in the use of iron and steel columns, girders, and joists, as a framework, with a mere facing of tile or brick, has enabled large constructions to be erected with a rapidity before unknown, and they have all the appearance of having taken years to build. The erection of the framework occupies nearly three-fourths of the time required to complete the building. The progress in construction has been marvellous for so short a time, the foundations have all been finished, many of the buildings have assumed a form which gives an idea of their grandeur, and one is exteriorly complete. The weather up to the end of the year was not unfavourable, and allowed of almost uninterrupted work. In December alone, 3,433,453 lbs. of iron and steel were brought to the ground, 5,306 car loads of material were delivered, 10,000,000 feet of lumber were consumed, and 1,446,200 lbs. of iron work were placed. The quantity of lumber required altogether for the buildings is 60,000,000 feet, and of iron and steel about 18,000 tons. The total quantity of staff required will be 84,000 pieces, of which 23,500 were cast up to the 1st January. The daily average of labourers employed in December was 2,824, besides 800 *employés*. Work has been proceeding day and night, by relays of labourers, as the agreement with the labour unions was that a day's labour should be eight hours.

Size, Cost, and Progress of the Exposition Buildings.

Administration. — The Administration Building has a dimension of 262 by 262 feet, covers 1·6 acres, and costs £87,000. With its gilt dome, it will perhaps be the most striking object in the grounds. It consists of a large rotunda 120 feet in diameter, and 220 feet in height, surrounded by a colonnade and four pavilions. The structure work of the latter and the exterior covering are finished. The ironwork of the rotunda is placed to the level of 170 feet, from which height the dome will spring. The pavilions, four stories high, will contain the offices and board-rooms of the different departments of the Administration, besides the fire and police departments, the

ambulance service, physician and pharmacy bureau, the bank, police-office, and other offices. Nearly £9,000 have already been paid on the contract.

Manufactures and Liberal Arts.—The Manufactures and Liberal Arts Building measures 1,687 feet by 787 feet, costs £300,000, and covers 30·5 acres. As yet £29,000 have been paid for work done. The 30·5 acres of floor are laid, and the superstructure is gradually showing above it. The huge steel trusses for the roof will shortly be raised. It will be the largest building ever constructed for exhibition purposes, and with its strictly Corinthian style, and the staff covering tinted to represent marble, will have a fine architectural effect. The central hall will have a clear space nearly a quarter of a mile long by 127 yards wide, and a height of 200 feet. As originally designed, there was an open court at each end, but these are to be roofed, to give more room, at an additional cost of £40,000, and, with the galleries, the building will have a floor space of 40 acres.

Mines.—The Hall of Mines and Mining is 700 by 350 feet, covers 5·6 acres, and is contracted for at the price of £53,000, of which £27,000 has been paid. This construction is far advanced; the framework and wood covering is completed, and finishing touches are being put on the iron and glass roof. The staff covering is being applied, and will be continued during the cold weather, as will be the case with all buildings ready to be covered, by erecting against the wall a moveable shed heated with a stove.

Electricity.—The floor of the Electricity Building has been laid some time, but further progress was stopped for the purpose of strengthening the foundations so as to enable them to bear the weight of the machines, which will be heavier than was anticipated. A large staff of men have however been employed during the last four or five weeks, and the framework is completed up to the gallery floor, and nearly all the great steel trusses for the roof are in place. The size of the building is 690 by 345 feet, the area 5·5 acres, and the cost £80,200. £17,500 have been paid on this contract.

Transportation. — Four months ago the Transportation Building had not been commenced, the site was an irregular sand heap, and the timber for construction was not on the ground. The framework is now practically completed as well as the roof sheathing over the galleries; the clerestory trusses are being raised, and when the glazing and putting on the staff is done it will be ready for occupancy. The main building is 960 by 256 feet, with an area of 5·6 acres, and the annex 900 by 425 feet, with an area of 8·8 acres, and the total cost is £74,000, of which £30,000 have been paid for work finished. This building will contain every description of exhibit devoted to the purpose of transportation. Immense freight sheds have been erected.

The Woman's Building is the nearest towards completion of all the constructions, the scaffolding being removed, and exteriorly, with the exception of the windows, it has assumed the appearance of a finished marble palace. The finishing of the interior is progressing. It measures 388 × 192 feet, and has an area of 1·8 acres, costing £27,600, of which £14,000 have been paid.

Art Galleries.—The Art Palace is built of brick, and has an area of 3·7 acres, being 500 × 320 feet; besides which there are two annexes, each 200 × 120 feet, giving an additional area of 1·1 acre, the whole costing £134,000, of which between £5,000 and £6,000 have been paid. The basement and floor are completed, and the brick walls have reached an average height of 10 feet above the second floor. More than five million bricks have been laid already. Space in this building has been applied for by several foreign nations. The Fine Arts Building has a total wall space of 145,852 square feet.

The present idea is that this building will be retained where it is as a permanent art gallery, as a survival of the Exposition, and that paintings will be gradually purchased for it.

Fisheries.—Two months ago the Fisheries Building was represented by a heap of lumber and a sawmill. The iron framework of the aquaria is now complete, the gallery trusses of the main building are placed, and the western pavilion is showing above the ground. The extreme length of the main building is 365 feet, covering an area of 1·4 acres; a curved corridor on each side connects it with two circular wings or pavilions 135 feet in diameter, one for the aquaria and the other for angling exhibits, giving a total length of 1,100 feet. The structure will cost £44,200, and £5,200 have been paid for carpentry and plaster model work done.

Horticulture.—The Horticultural Building is 998 feet long by 250 feet broad, and consists of a central domed pavilion and two side pavilions, joined by curtains forming interior

courts, and covers 5·7 acres. The cost is £60,000, of which £10,000 have been paid for carpentry and modelling done. There will, besides, be eight greenhouses, 100 × 24 feet, covering half an acre, and costing £5,000. The pavilions are constructed up to the roof line; the west curtain is complete as far as the woodwork is concerned; the roof is glazed, and windows are being placed; lack of iron has delayed the construction of the dome, but the ironwork is now being put in position.

Machinery.—The Machinery Building is the most expensive of all the constructions, costing £240,000, but as yet only £3,000 has been paid for work done. The dimensions of the main building are 846 by 492 feet, with an area of 9·6 acres, and those of the annex 550 by 490 feet, having an area of 6·2 acres. The floor of the main hall is laid, and 6,000 supporting pillars are erected, and the foundation of the annex is being laid. The whole length of the construction is 1,400 feet, and the architectural effect of the main hall will be very fine. There will be also annexed a power-house, pumping works, and machine shop, covering 2·1 acres, at an additional cost of £17,000.

Agriculture.—The main Agricultural Building is 800 feet long by 500 wide, and covers 9·2 acres; the annex is 560 by 300 feet, with an area of 3·8 acres, and together they will cost £123,600, besides which there will be an Assembly Hall, &c.; 400 by 120 feet, which will cost £20,000. £18,500 have been already expended for carpentry and modelling work. The interior columns and gallery girders and joists are in position, and the iron columns to support the roof are being placed; numbers of workmen are engaged in erecting the woodwork, which to the extent of 7,000,000 feet of lumber is already sawn for the construction, and more than half is already placed.

Saw-mill.—At the back of the Agricultural Annex is a saw-mill 300 by 125 feet, having an area of an acre, and costing £7,000.

Forestry.—The forestry building is situated in the south-eastern part of the park, and costs £20,000; it has an area of 2·5 acres, being 528 by 208 feet. It is about three parts finished, and will be occupied by the model makers till the spring, when the rustic work will be put on, and the temporary roof replaced by a thatched one.

Dairy.—The Dairy Building lies just beyond the Forestry, measures 200 by 100 feet, with an area of half an acre, and will cost about £6,000. All the columns are up to the roof line, and the gallery floor is being laid.

Live Stock.—The Live Stock Buildings, pavilion, and sheds will cover 43·7 acres, the ground given up to that department being altogether 63 acres, and the cost of construction will be £67,000.

Pier and Casino.—A pier 80 feet wide runs out from the north-east corner of the architectural building, stretches 1,200 feet into the lake, and at right angles to the extremity run two shorter piers, forming a harbour, inside the northernmost of which, facing the basin and Administration Building, is situated the Casino, of Venetian architecture, built on piles, the seven separate pavilions of which are intersected by water. The Casino is 250 by 120 feet, and, with the Music-hall, will cost £42,000.

Other Works.

Besides the main buildings a great deal of other work has been done towards carrying out the plans adopted by the Grounds and Buildings Committee.

Woter Supply.—To supply the buildings and grounds with water two plants are to be put in with a capacity, one of 24,000,000 gallons a day, the other 40,000,000, making a total of 64,000,000 gallons a day. The machinery will shortly be installed.

Drainage.—A system of drainage and sewerage has been adopted, which is believed to be adequate and perfect. The work is progressing fast. All refuse will be received by injectors and forced by compressed air through underground pipes into four huge tanks, where it will be treated chemically and rendered inoffensive.

Lighting.—The plans for lighting are also being actively carried out. The electric plant will require 22,000 horse-power, and the plans are adopted for providing 138,218 lamps, of which 6·766 will be arc lamps of 2,000 candle-power each, and 131,452 incandescent lamps of 16 candle-power each. The effect of the electric lighting will be greater than has ever yet been produced. An immense railway station is being laid out to the west of the Administration Building, in conjunction with the railway system and bridges and viaducts are in course of construction.

Bazaar.—The Midway Plaisance is set apart for the bazaar of all nations, and contracts have already been entered in this space for a typical Egyptian street, and a section of Constantinople, to cost together £300,000; a

German village, Moorish palace, a Maori village, and other constructions of a similar character, for which concessions have been granted. An additional charge will be made for visiting this part, which will be outside the Exposition proper.

Government and States Buildings.

The United States Government appropriated £300,000 for the World's Columbian Exposition, of which sum £80,000 was set aside for building, and a great portion of the remainder has been spent in National Committee expenses and preparations for Government exhibits. It is expected that a further appropriation will be made, the cost of awards (£140,000), the awarding juries, and further National Commission expenses. The Government Building measures 415 feet by 345 feet, covers 3·3 acres, and costs £80,000. Work is rapidly being pushed on. The imitation battle-ship, also constructed by the National Government, is built of brick, in the lake, a short distance from the shore, and is completed to the deck level. It is 348 by 69·25 feet, and costs £20,000.

Twenty-six States and territories have already made varying appropriations for their separate State representations, amounting in the aggregate to £539,000. This sum will be largely increased, as, in many cases, the vote is only preliminary; in some, money is being raised by subscriptions for further representation, and the legislatures of other States have yet to fix upon the sum they intend to appropriate. In the State of New York it is said a proposal will be submitted for an appropriation of £300,000. Plans for the buildings of some of the States have been approved, but their construction has not yet been commenced, except in the case of Illinois State Building, which is progressing rapidly, and, with its two wings, will cover 2 acres, and cost £50,000. All the States buildings will be clustered together at the northern part of the park, in the neighbourhood of the ground reserved for foreign countries. It is expected that the separate expenditure of the several States and Territories will exceed £1,000,000, 44 States and 5 Territories having signified intention to participate.

Foreign Countries.

Thirty-nine foreign nations and 24 colonies have signified to the Direction their intention of participating in the Exhibition. Their names, and the amount of their appropriations, made or proposed—as far as yet known—are as follows:—

Country.	Appropriation.
Argentine Republic	£20,000
Austria	29,850
Belgium	
Bolivia	20,000
Brazil	120,000
China	
Chili	20,000
Colombia	20,000
Costa Rica	20,000
Denmark	
Danish West Indies	
Ecuador	25,000
Egypt (informal)	
France	80,000
Algeria	
Germany	52,840
Great Britain	25,000
Barbadoes	1,200
British Columbia	
British Guiana	5,000
British Honduras	1,500
Cape Colony	5,000
Ceylon	8,000
India	
Jamaica	4,000
Malta	
Mashonaland	
New South Wales	30,000
New Zealand	
Queensland	
South Australia	
Tasmania	
Great Britain—	
Trinidad	£3,000
Victoria	15,000
West Australia	
Guatemala	24,000
Hawaii	
Hayti	
Honduras	4,000
Italy (informal)	
Erythria	
Japan	126,153
Korea	
Madagascar	
Mexico	150,000
Netherlands (informal)	
Dutch Guiana	2,000
Dutch West Indies	1,000
Nicaragua	6,000
Orange Free State	
Paraguay	5,000
Persia	
Peru	25,000
Russia	
Salvador	1,400
San Domingo	
Siam	
Spain	
Cuba	5,000
Transvaal	
Turkey	
Uruguay	
Venezuela	
Total	£845,915

Besides the above-named countries, the appropriations of which it is assured will in many cases be increased, it may be considered certain, from information received by the Direction, that Sweden, Norway, Hungary, Switzerland, Canada, and several others will be added to the list; and, at a low estimate, it is thought the appropriations of foreign nations will amount to £1,000,000 sterling. Building sites have been selected for Great Britain, Germany, Japan, Turkey, Mexico, Peru, Brazil, Ecuador, Colombia, Costa Rica, Guatemala, and Chili, and the constructions of foreign countries will be of very varied description. Zanzibar alone has reconsidered its acceptance of the invitation to participate.

TRANSPORTATION.

To the grounds.—The only drawbacks to the site of the Exposition are its distance of seven miles from the centre of the city, and the distance Chicago is from the Atlantic. At present, the Illinois Central Railway, which runs along the borders of the Lake, conveys home daily, between the hours of 5 and 6.30, about 5,000 people out of the city in the direction of Jackson-park, and during the same time, about 40,000 people daily travel home by cable and horse car. These modes of conveyance may extend their capacity, and the elevated railroad, which has been partly completed, will no doubt be ready to bear its share. It is also expected that steamboat companies will start lines from the city to the park, and that the means of reaching the ground will be increased, so that a maximum of 400,000 can be daily conveyed to and from the Exhibition. The peculiarity, however, of Chicago is that, though it occupies an enormous extent of ground—178 square miles—the principal business, the hotels, stores, public buildings, and the railway and car termini, are almost all concentrated in about one-half mile square, and from the configuration of the city, and the north and west sides being separated by the river from each other and from the south side, almost everything passes through that small northern part of the south side, which is now much crowded.

In the grounds.—With regard to the conveyance of people round the grounds, plans are not definitely adopted, but several companies are ready to provide the means, and the only decision arrived at is that the tracks must be elevated. One of the plans now under trial is a continuous movable sidewalk, or platform, with a capacity of 40,000 an hour, to be continually moving at the rate of three miles an hour, and alongside it another platform moving at the rate of six miles an hour. The portion on trial has been working for the last month, and has met with general approval, the habit of getting on to the platform in motion being quickly acquired. Definite arrangements are yet to be perfected for the conveyance of visitors to Chicago from different parts of the country, but reduced rates, it is said, will prevail.

Freight for Exhibits.—With regard to freight rates for exhibits, arrangements have been made with nearly 500 railway and steamship companies. The following memorandum has just emanated from the Direction at Chicago:—

"Freight rates: on the subject of freight rates from the seaboard ports to Chicago, on exhibits for the World's Columbian Exposition, to be held in 1893, it may be announced that the following arrangements have been perfected, which, however, are subject to a modification which it is hoped may be effected. The Freight Traffic Association of the country, of which the leading transportation lines are members, have uniformly adopted a tariff of full rates on the forward journey, granting free return of the exhibits to the seaboard, provided ownership remains unchanged.

"The following schedule of class rates in effect at the present time (December, 1891) between the principal seaboard ports and Chicago (subject to change) are:—

From	1st class.	2nd class.	3rd class.	4th class.	5th class.	6th class.	A.	B	C	D
New York	75	65	50	35	30	25				
Philadelphia ...	69	59	48	33	28	23				
Baltimore	67	57	47	32	27	22				
Boston...........	75	65	50	35	30	25				
Portland Me...	65	57	44	3	26	22				
Newport News	59	51	43	29	25	20				
Montreal	65	57	44	31	26	22				
New Orleans...	1·18	98	78	61	50	44				
San Francisco.	4·20	3·70	2·95	2·30	2·00		2·00	1·80	1·45	1·30
Portland Or....	4·20	3·70	2·95	2·30	2·00		2·00	1·80	1·45	1·30

"To the above rates there will be added a sum not to exceed 8 cents. per 100 lbs. This is a terminal charge covering the switching of exhibits into the Exposition grounds from the point of intersection with the Illinois Central Railroad, and the placing of exhibits on or adjacent to the space allotted. This charge of approximately 8 cents will be made in both directions.

"From the above it will be seen that freight rates from New York to Chicago, including switching and terminal charges, as specified above, vary from half a cent to one and a half cents per ton per mile.

"When property is shipped on a through bill of lading, to and from Chicago, there will be no charge for transfer from steamer to rail at the seaboard.

"The class rates herein quoted will, it is be-

lieved, cover such exhibits as are not of a particularly high grade.

"Exceptionally fine goods, such as statuary, paintings, and fragile articles, which are classified from one and one-half to double first-class, are charged at proportionally higher rates than those scheduled.

"Freight charges on exhibits must be prepaid at the point of shipment, the goods being delivered at the Exposition clear of all charges incident to their transportation.

"A condition of the free return of unsold exhibits is that they shall be transported over identically the same routes as were used in forwarding them to Chicago.

"*Storage Rates for Empty Cases.*—The maximum charge for removing, storing, and returning empty cases, and packing material, without insurance, two (2) cents per cubic foot. For empty cases and packing material, with insurance, two and one-half cents (2½) per cubic foot. Neither these storage rates nor the terminal charge referred to above are definitely determined. It is hoped that both may be modified.

"The following statement, reproduced for comparative purposes, shows the cost of similar service at other Expositions :—

			Per Cubic Feet.
London	1862		$·059
Vienna	1873		·02
Philadelphia	1876	(without insurance)	·018
Paris	1889	(„ „)	·029
Paris	1889	(including insurance)	·162

"While the arrangements with trans-oceanic and other steamship lines are as yet incomplete, the Exposition management has every reason to believe that liberal concessions will be made by all the leading lines touching at New York and other seaboard ports."

Insurance.

The amount of insurance placed on the main Exposition buildings up to the end of the year exceeded £200,000, and this will be gradually increased as their construction progresses. It is estimated that not less than £35,000,000 or £40,000,000 insurance will be eventually carried on the buildings and exhibits. The Exposition ground is already provided with a full equipment of fire engines and apparatus, and every precaution is being taken against fire.

Insurance Memorandum.—The following Insurance Memorandum was issued on the 6th January, 1892 :—

"The Insurance Auxiliary Committee has suggested that insurance, both marine and fire risks, be obtained in the country from which exhibits are sent. The Committee is unable to name the ocean rate, as it varies according to the port.

"The fire risk of Exhibition buildings, at present, would be at the building construction rate, which will be modified somewhat when the buildings are completed. On the temporary Insurance Diagram, attached herewith, will be found the present rate marked in blue pencil.*

"To obviate the difficulty of obtaining full fire insurance in this city on exhibits, which will probably begin about the end of this year, the Committee suggest that exhibitors obtain in their own country as much insurance from domestic companies as possible.

"No arrangement has been perfected as to insurance of goods while on exhibition, but the Committee will have prepared, some time prior to the arrival of exhibits, a schedule of insurance acceptable by the majority, if not all, of the sound fire insurance companies of the world, so that owners desiring insurance to be placed here will have all information."

General Regulations.

Information for Foreign Exhibitors.—A further circular of information for foreign exhibitors has lately been issued, embodying the regulations governing the free import of articles for exhibition, issued from the Treasury Department at Washington on the 5th November last. (Copy forwarded in Despatch No. 5, Commercial, of the 19th December, 1891.) Though free of entry for exhibit, duty will be levied on all goods sold in the country. Articles will not be received after the 10th April, 1893. If articles are for competition, it must be so announced. No charge for space or limited power is made. The mode of addressing articles must be strictly adhered to, and facilities will be afforded for the through transit to and from Chicago. The exhibitor must be bound by the regulations contained in the circular.

Classification.—A new classification has been issued, comprising 12 departments, 126 groups, and 968 classes. (Copy forwarded in Despatch No. 7, Commercial, of the 29th December, 1891.)

* This diagram is merely a plan of Jackson-park, similar to that which appeared in the *Journal*, December 11, 1891.

WORLD'S CONGRESS AUXILIARY.

The World's Congress Auxiliary will be a great attraction and feature connected with the Exposition. It is recognised and approved by the United States Government, and is organised to provide for the presentation, by papers, addresses, and discussions, of the mental and normal status and achievements of the human race. The Congress embraces a number of Departments, such as literature, Government, education, music, science, engineering, &c., in each of which there are subdivisions. It is believed there will be at least 100 congresses held. A building capable of holding a large number of persons will be constructed for this purpose on the Lake front. Congresses of artists, including every branch of art, will form a feature of the World's Auxiliary Congress. A General Committee has been formed, with Sub-Committees, on the Congresses of architects, painters, sculptors, and decorative artists. The topics of discussion embrace all subjects relative to the various branches of art.

OTHER ATTRACTIONS.

In the Women's Building will be afforded the opportunity of showing the achievements of the sex, and the adaptability of women to different occupations in industry, charity, and other work. The most excellent specimens of their work from all countries will be collected in this building.

As an American Exhibition it will be unique, and one of the most striking and novel features will be the extensive exhibits from Mexico, Central, and South America, which have had no such former facility, or availed themselves in such a degree as is now assured of similar opportunities of representation. The horticultural show promises to be brilliant and various. Almost every foreign country has applied for space in the building, 43,800 feet having been already allotted, besides 275,000 feet outside the building. There will be exhibits from all parts of the world, where collectors are busy, as well as from the States of the Union, for each of which space is reserved.

Music and concerts will be carried on on an extensive scale. A great display of fireworks will take place at night. A number of restaurants will be provided, capable of seating 8,000 people, and several thousand seats will be placed in the grounds. It is decided that liquor will be allowed to be sold. A natarium, and every description of bath, will be furnished on the ground, and a number of other constructions not here enumerated.

The city itself affords many attractions from the wonderful rapidity with which it has sprung up, its energy, its buildings and manufactures, and its great system of parks, connected by forty-five miles of boulevards. The city will spend a large sum—about £400,000—in putting the streets and parks in thoroughly presentable condition by the time the Exposition opens. About twenty new hotels are in course of construction for the accommodation of visitors.

An International Naval Review is planned for April, 1883, in New York Harbour, and the mobilisation of 10,000 Militia and several thousand regulars, while the Exposition is open, is also contemplated.

PROSPECTS AND ADVANTAGES OF EXHIBITS.

Prospects of Exhibits.—Applications for space from the different States of the Union are coming in fast; more than 2,000 have already been made, and the greatest assurance is felt that the representations of the separate States will be on a very extended scale. A few exhibits have already arrived. From foreign countries the information received by the management is considered most encouraging, and reports from the Commissioners now visiting the South of Europe, and from other agents, are said to be highly satisfactory. Interest appears to be very generally taken, in almost every quarter of the globe, with a view to a thoroughly representative show. New plans for various exhibits are constantly being received by the Management, and applications for space are described as overwhelming. A few days ago, New South Wales asked for 200,000 feet. In the Art Galleries, where space has been already allotted to a few foreign nations, France has recently applied for 82,000 feet. Everything tends to show that the representation of foreign countries will be of a most comprehensive and wide character, and the thought is beginning to arise that it will be more a question whether the buildings, enormous as they are, will be large enough to contain all the exhibits which promise to arrive, than that there will be space unoccupied. The position of the Exposition is already assured, unless some unforeseen incident occur, as the largest and most comprehensive exhibition ever held.

Advantages.—With regard to the advan-

tages of exhibiting, it must be borne in mind that the Exposition is a thoroughly international one, and not only that the best productions from all parts will be brought together, but that it will be visited by a multitude of people, many of them the most intellectual of all countries. It will afford the exhibitor an unequalled opportunity for his goods to be seen and compared with those of other nations. It will afford the widest scope for increasing commercial relations with this and every other country, and the field offered by the United States is a large one. Every year the population and the demand for every article increases, as well as the money at disposal for the purchase of works of art, glass, china, and all fine goods. Notwithstanding the heavy duties, which may some day be changed by a liberal policy, there is still a demand for those articles which cannot be produced to such perfection in the United States, and a risk is run by those who do not exhibit of losing the foreign customer they now have, which may be taken by those who do. The Exposition may also lead to a wider appreciation of the foreign production, and possibly to the establishment of branches or agencies which are practically non-existent in this part of the country. In these days of high competition, too, when foreign nations will have a hard fight to maintain the position they hold in the markets of Central and South America, it is of no small importance that British goods should be well represented, so that their quality may be seen and compared not only with American but with other European goods, and the price at which they can be furnished more widely known.

Labour Contract Law.—It is assured that the Contract Labour Laws will not in any manner stand in the way of foreign exhibitors importing persons in their employment for Exposition purposes, as in the opinion of the highest legal authority in the country such persons would be outside the intention of these recent laws.

Patents.—With regard to patents, the American law is of a liberal character, and from information received from the World's Fair Commission, some particulars on the subject will shortly be circulated.

Dedication and Opening.

The World's Columbian Exposition is under the auspices of the United States Government. The buildings, which will then be completed, will be dedicated, with inauguration ceremonies extending over three days, on the 12th October next, the 400th anniversary of the discovery of America by Columbus, when the President of the United States, the Senate and members of Congress, the Governors of States and their staff, and the representatives of foreign countries will be invited. The time between October 12, 1892, and the 1st May, 1893, when the Exposition will be open to the public, will be occupied in receiving and arranging exhibits. The Exposition will close on the 30th October, 1893, and all exhibits must be removed by the end of the year.

Proceedings of the Society.

EIGHTH ORDINARY MEETING.

Wednesday, February 3, 1892; CHARLES MALCOLM KENNEDY, C.B., Member of the Council of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Clarke, Somers, 15, Dean's-yard, Westminster, S.W.

Goodman, Professor John, The Yorkshire College, Leeds.

Handcock, Henry W., Lanorna, Blyth-road, Bromley, Kent.

The following candidates were balloted for and duly elected members of the Society:—

Barrett, Arthur, 114, High-street, Kensington, W.

Foord, Alfred Stanley, Tay-villa, Richmond-gardens Romford-road, Forest-gate, E.

Hindmarsh, George Lisle, 29, Regent-quay, Aberdeen.

Hughes, Thomas W. R., 11, George-lane, Lewisham, S.E.

James, J. H. Cordner, 10, Mansion-house-chambers, 11, Queen Victoria-street, E.C.

Jarman, Captain Stephen, R.N.R., Dartmouth villa, Evering-road, Clapton, N.E., and 19, Birchin-lane, E.C.

Maund, John Oakley, 80, Portland-place, W.

Watney, John, Mercers'-hall, E.C.

Wyon, Allan, 2, Langham-chambers, Portland-place, W.

The paper read was—

DUST AND FRESH AIR: HOW TO KEEP OUT THE ONE AND LET IN THE OTHER.

By T. Pridgin Teale, M.A. Oxon., F.R.S.

Except in the case of museums, few serious attempts have been made to exclude dust from rooms, closets, cupboards, and drawers, to the contents of which, not unfrequently, dust is simply ruinous. We allow dust to run riot amongst our things of value, and then go to considerable expense to render them clean again, only to start them on a fresh career of defilement.

Looked at in the abstract, is not our passive capitulation to dust incomprehensible? When I enter an office in a town and see the window sills and papers dotted with soot, or go into a bedroom and see the toilet table defaced with blacks, and know that the soot and the blacks need not be there, I cannot refrain from asking how comes it to pass that we so patiently submit to such perpetual discomforts. You will doubtless reply, We agree with you as to the existence of the evil, but how is it to be remedied? The object of my appearance here to-night is to offer some practical suggestions whereby you may so far mitigate and reduce the evils of soot and dust as to make them tolerable, perhaps even to lay down principles by which the evils can be annihilated in those instances in which the result to be obtained is worth the cost of achievement. For the practical purposes of everyday life it may turn out that we had better be content with approximate perfection, a condition of existence which compels us to be content with approximately pure water from a filter, and approximately pure air in our living rooms.

How does Dust get in?

If dust is to be kept out of any cavity, we must first find out why the dust gets in, in spite of good workmanship and accurate fitting. The reason is simple, ridiculously simple when stated, but, curiously, it has been little, if at all, thought of, and certainly hardly ever acted upon in practice. And the reason is this. Closets, cupboards, drawers, and boxes contain air; if the air were inelastic and never altered in volume there would practically be no entrance of dust into these closed cavities. Unfortunately for our cleanliness, air is changing in volume incessantly. We are all familiar with the barometer, and most of us no doubt understand why the quicksilver rises and falls in the glass tube, or why, in the aneroid barometer, the index moves to right or left. Let us consider what these changes mean, and what they record.

When the air around us becomes condensed—shrinks into a smaller volume—it becomes heavier, puts greater pressure on the surface of the mercury, and makes it ascend in the tube; then the mercury is said to rise. When the air expands—swells into a larger volume—it becomes lighter, the pressure on the mercury is less, the mercury sinks in the tube, and the barometer is said to fall. Therefore, every change of height of the quicksilver which we observe is a sign and measure of a change in the volume of air around us. Further, this change in volume tells no less upon the air inside our cases and cupboards. When the barometer falls, the air around expands into a larger volume, and the air inside the cupboard also expands and forces itself out at every minute crevice. When the barometer rises again, the air inside the cupboard, as well as outside, condenses and shrinks, and air is forced back into the cupboard to equalise the pressure; and, along with the air, in goes the dust. The smaller the crevice, the stronger the jet of air, the farther goes the dirt. Witness the dirt-tracks so often seen in imperfectly-framed engravings or photographs. Remember, ladies and gentlemen, whenever you see the barometer rising, that an additional charge of dust is entering your cupboards and drawers. So much for the barometer, which is a very restless creature, rarely stationary for many hours together. But this is not all. We also have the thermometer. The temperature of our rooms varies daily—often considerably—between mid-day and midnight, and greatly between summer and winter. What does the thermometer tell us? Not less than the barometer does it tell of change of volume of the air, though it is probably not so rapid in its effect upon the air in enclosed spaces as is the change of volume indicated by the barometer. Many of you have seen a fire-balloon. The heated air, filling the balloon, expands, and becomes lighter than the surrounding air, and up goes the balloon, until, the source of heat having become exhausted, the contained air cools, contracts, becomes as heavy as the surrounding air, and down comes the balloon again. So, also, as temperature rises outside our cases, the increased warmth is slowly conducted to the air inside the case, which expands and escapes through the crevices. Then, when the time for cooling comes, the

air inside slowly contracts, and back rushes the air through the crevices, and again in goes the dust. Thus, we see we have two factors constantly acting, one or other tending to produce daily, nay, hourly, changes in volume of our dirt-carrying air.

In order to inform myself of the amount of change of volume that could, under extreme conditions, possibly take place, I asked Professor Rücker to kindly calculate for me the change of volume that would take place in 100 cubic feet of air, between a temperature of 30 degrees, *i.e.*, just above freezing point, in combination with the barometer standing at 30 inches, or about "fair," and a temperature of 60 degrees, combined with the barometer standing at 29 inches, or "stormy." He told me that the difference would be about 10 cubic feet, or one-tenth; in other words, that a closed case of 100 cubic feet, if hermetically sealed at a temperature of 30 degrees, with the barometer standing at 30 inches, would have to resist the pressure equivalent to the addition of 10 cubic feet, when temperature rose to 60 degrees, and the barometer fell to 29 inches. Have we not now discovered the reason why dirt enters closed spaces? What shall be the remedy?

Seeing, then, that air will find an entrance, and in the nature of things must get in—well, we must let it in, not at innumerable uncovenanted small crevices, but at our own selected opening, specially provided. Then we are in a position to strain off the dust by providing the selected opening with a screen, which acts as a filter. These, then, are the general principles on which we must act. The rest is a question of detail. The details range themselves under three heads:—1. What is the most effective, or the most generally applicable filtering material? 2. Given the filtering material, what ought to be the proportion between the area of the screened opening and the cubic contents of the case to which it has to be fitted? 3. What, in any particular instance, is the best situation for the filter?

A.—Filtering Material.

What is needed in our filtering material is that it shall readily allow air to pass through, and shall also possess the quality of arresting in its meshes fine particles of dust. For some purposes it may suffice to use a coarse canvas, the threads of which are not too closely twisted and have an abundance of fine fibres projecting from them, thereby reducing the small squares of the woven texture to a still finer mesh. The material I have used most frequently is "bunting," but it has disappointed me. When examined by the microscope many of the small squares of mesh are seen to be deficient in delicate fibres standing out from the threads, which would enhance the filtering power of the texture. Lately I have tried other materials, domette, flannel, and cotton-wool between layers of muslin, such as is used for dressing wounds under the name of Gamgee tissue. Cotton-wool is probably the most perfect filter. Indeed, so perfect is it that in the new science of bacteriology it is used as an effective means of excluding dust and germs from flasks in which experiments are to be carried on. In order to put various textures to an exact comparative test, an experiment was tried. Having selected six quart bottles with wide mouths, I tied over the mouth of each a piece of the filtering tissue which I wished to test. The bottles are not liable to crack, as wooden boxes are; the only access for the interchange of air in the interior was through the filtering texture. I thus had a means of testing the comparative value as strainers of the various materials. Within the bottles were placed glass slides on which any dust that was carried in might settle. The experiments were begun on May 5th, 1891, and the slides were taken out on January 6th, 1892, and most carefully photographed by Mr. Lafayette, and made into lantern slides.

The bottles were placed near a window in a room in the building of the Leeds Philosophical Society, *i.e.*, quite in the centre of Leeds. The materials tested were:—

Canvas.
Bunting.
Ordinary flannel.
Domette flannel, rough side in.
Domette flannel, rough side out.
Cotton-wool, 1 inch thick.

The results of the experiments are now shown you by the lantern. It will be seen that as a consequence of eight months exposure, including a week of the worst fog I ever knew in Leeds, three of the filtering tissues admitted a very appreciable amount of dust, viz., coarse canvass the most, bunting coming second, ordinary flannel admitting less than either. The other three bottles were screened, one with thick domette rough side in, one with domette rough side out, and one with cotton-wool about an inch in thickness. The three last show hardly a trace of dust. Curiously, the cotton-wool shows a trace more than

the domette flannel. The explanation of this I suspect to be that the cotton-wool was not tied firmly enough round the neck of the bottle, which had no rim, and that some air passed between the bottle and the wool, instead of through the wool.

Another experiment which I tried was to fit up a cupboard with panels of double domette flannel. After the fog, to my surprise, the inner screen had become more or less black, showing that black particles had passed into the cupboard, but with this remarkable difference: whereas the outer flannel was almost uniformly black from top to bottom, the inner flannel was divided into four squares of different shades of blackness, corresponding to four spaces between shelves. Of these four, the lowermost was almost as black as the outside, and the uppermost was almost clean. I just mention this as a fact which needs an explanation, but without suggesting one.

There is one error which I think has been committed in the screens made for me, and it was pointed out by my friend Mr. White, the architect, of Wimpole-street. The filtering material is likely to act more effectively if left loose and not stretched tight, as when tense the interstices are stretched and made larger, and when out of sight it might be very loose, almost baggy, with advantage.

Hoping to get some hints as to the comparative value of the various textures under trial, I placed specimens of each under the microscope. It is obvious that both canvas and bunting are of too open a texture, having numerous small holes unguarded by delicate fibres. Judging by the microscope, one would conclude that of woven textures, probaby flannel, and still more, domette flannel, are the best, and this judgment seems to be borne out by the experiments with the bottles.

B.—The Proportion between the Filtering Opening and the Cubic Contents.

This is a question which experience alone can decide. Doubtless the larger the area of screened opening, the more effective the filtration. For a bookcase with glazed front, probably the whole of the back might be made of flannel loosely fixed over the necessary skeleton framework. For a cupboard or closet, every panel should be replaced by a screen. If the closet have a window, all crevices and joints in the window should be pasted up to exclude the soot, otherwise the wind from the outside, or the fires of the house from the inside, will force the air soot through. On the other hand, it is probably true that, given very perfect fitting and workmanship, aided by the interposition of velvet, as hereafter described, where the edges of the doors come into contact with their frame, a much smaller area of filter, perhaps even a simple tube, filled with cotton-wool, may prove to be efficient. These, however, are points on which further experience is needed, and which may, ere long, be settled by experiment.

C.—The Situation of the Screened Opening.

Where shall we place our screen? This is a question which admits of a variety of answers, and gives scope for endless ingenuity. In anything which is being newly made, such as the cupboards and closets of a new house, or in new furniture, we are masters of the situation. In many of them we may substitute at the back our filtering texture for wooden boards, and perhaps even save expense thereby. In closets we may replace the panels of the door by filtering texture, guarding the closets, if necessary, against thieves by wire netting or iron bars fixed on the inner side. As a rule, chests of drawers may have the filter over the whole surface at the back, care being taken that the back of each drawer falls half an inch short of the top of the drawer, to allow free entrance of air from the screen. In one set of drawers, so placed that I could not get at the back, the difficulty was got over in this way:—In the front of each drawer a series of twenty holes, of an inch diameter, was made for admission of air. The filter, on a frame, was fixed on the inner surface of the front of the drawer, so that the material should stand half an inch away from the holes. A somewhat similar plan was adopted in a bureau. About 20 large holes, two inches in diameter, were cut in the woodwork at the back, some of the holes being opposite pigeon holes. Then the whole was covered with bunting, on a frame so arranged that the bunting was fully half or two-thirds of an inch away from the wood. Another method has been adopted at the Yorkshire College for some of the cases. The filter was applied at the roof, somewhat after the fashion of a weaving-shed roof, the vertical face being filled in by the screen. Again, Mr. Branson has provided a roof filter for a case of scientific instruments, by placing the screen in the roof of the case, and protect-

ing it by a false roof two inches above it, to prevent its being choked by falling dust.

How to Deal with Crevices.

What shall we do with crevices and cracks? At first, I hoped that narrow chinks might be ignored, on the principle that easy passages of air through an ample screen would virtually stop off currents through narrow spaces. In this I have been disappointed, as, in some cases, a chink, though apparently narrow, has proved too accommodating to the passage of air, and a more ready channel than the interstices of flannel. My rule now would be to close or guard with filtering material every place where the door comes into contact with its frame.

The plan I have adopted with the doors of several cupboards and closets is this—to put strips of cotton velvet wherever the door comes into contact with its framework. On the side where the hinges are, the velvet is glued and sprigged to the edge of the door: on the other side and the top the velvet is fixed to the rebate against which the door presses. If the door belong to a closet, and the bottom is not in close contact with the floor, a small piece of flannel or cloth may be fixed along the inner side of the bottom of the door, so as to form a curtain which closes the gap, and filters any air that passes through.

Such, then, are the principles which may guide us to a victory over dust, and such are some of the details whereby we may work out a method by which the victory is to be won. Do not suppose that I claim to have completely conquered the enemy; but a beginning has been made, a beginning definite enough and assured enough to encourage others, and especially architects, to study the question and to make trials. If they will but work with determination to conquer, they may confer upon the community a most welcome amelioration of some of the smaller miseries we have to submit to.

A Model Room.

And now let me venture to tell you what I should do were I to construct an office in the centre of a town. I should begin with the fireplace. Let it be constructed on the principles I have been teaching for the last ten years, and which were brought to a focus in my lecture at the Royal Institution in 1886; principles which are at last influencing the construction of firegrates throughout the kingdom. Shortly stated, they are:—

1. The back and sides of the fireplace to be firebrick, built solid.
2. The depth of grate from front to back never to be less than 9 inches.
3. The back to lean over the fire, not to lean away from it.
4. The front bars to be vertical and thin, not horizontal and thick.
5. The ashplace under the grid to be made into a closed hot chamber by a moveable shield, named an "Economiser."

The effects of this construction are:—

(*a.*) Great diminution of dust, since the ashes fall into a closed ash chamber.

(*b.*) Better warming of the room, with a diminution of about one-fourth in the quantity of coal used.

(*c.*) Diminished draught across the floor, from diminished roar up the chimney when the fire is burning briskly.

(*d.*) Diminished production of soot.

These are the principles which I have urged, and they are open to everyone to adopt. I do not speak of a further improvement, as it is the subject of a patent, and is not open to everyone to copy.

Having made sure of my fire, the next step would be to secure admission of air to supply the fire, without making a draught or introducing dirt. As far as I know this is best done by the "Harding diffuser," which admits air directly from the outside and delivers it through a series of small jets near the ceiling. To shut out the smuts the air passes through a canvas screen placed diagonally in a flat tube, which leads up to the "diffuser" and gives a filtering area about six times the sectional area of the tube. This air is admitted into the room by a legitimate channel, and is filtered. The "Harding diffuser" was once patented, but the patent has lapsed.

Having thus secured a supply of air for the chimney, we can afford to deal with the windows, and make them air-tight, without fear of the chimney smoking. Now I should like to see a revolution in windows, at any rate, wherever we can be content with panes of moderate size, and can have the heart to surrender plate glass.

Three things are required of a good window.

1. That the outside of the window may be cleaned by a servant standing inside the room, whereby the risk and expense of cleaning from without is avoided.
2. That it shall exclude wind and dirt, even under the stress of a gale.
3. That the air of the room, especially in

frosty weather, shall not be itself so chilled by contact with the large surface of glass as to cause induced cold currents, which have not even the merit of being air freshly introduced.

To attain these points, the sash window must be abandoned. The window must be so divided that one half vertically, or in a large window one-third, may open inwards on hinges, the other half or two-thirds being fixed, and therefore wind tight. The breadth of each division to be such that a servant's arm can reach out and clean the outer side of the fixed window as she stands inside the room. In the case of three divisions the fixed windows would be to the right and left of the hinged window. The hinged window should be in two or three divisions, according to the height, not in one large casement from top to bottom. Thus have we provided for my first requirement, the cleaning of the window. The hinged window must be so constructed that when closed the framework of the window locks into a double rebated fast frame, after the manner of a jeweller's show case. Then, if well made, it would fit tight and keep out wind and dust. This provides for my second requirement.

Lastly the panes should be doubled, that is, a second pane must be placed inside the ordinary pane at a distance of about 5-8ths of an inch. The outer pane is fixed by putty in the usual way. The fixing of the inner pane is peculiar and all important. The inside of the frame is cut to receive the glass exactly in the same manner as the outer side for the outer pane, but the inside pane must not be fixed by putty, but is held in place, "sprigged" firmly against its rim, "the rebate," by small nails, two in each side, very carefully put in. Why do I insist upon this mode of fixing the inner pane? For two reasons—one, to make it easy to remove the inner pane if ever it should be necessary to clean the inside of the two panes; the other reason is, to enable me to render cleaning of the inside unnecessary. How is this achieved? By facing the flange, against which the pane is pressed, with cotton velvet. The air that must perforce pass in and out of the space between the panes must pass the velvet, and be filtered. Two windows of my bedroom thus treated five years ago have never needed to be cleaned; and a pane, which was removed at the end of four years for inspection, was absolutely clean. Another advantage of the double panes is this:—When my other windows with single panes are steamed all over, and even glazed by the frost, the outer panes of the double window show hardly a trace of unfrozen steam; the inner panes are never steamed. Again, a thermometer placed between the panes has never been below 30° all this severe weather, even though a thermometer outside the window has been several times below 20°.

Lastly, I would treat the cupboards and drawers after the manner already described. The result would be, not absolute freedom from dirt, nor absolute protection from London fog, but such a departure from what is commonly experienced as to make the experiment well worth all the trouble it costs.

DISCUSSION.

Sir HENRY TRUEMAN WOOD said the first objection to Mr. Teale's ideas was, that the carrying of them out demanded so much better workmanship than the ordinary workman would give, or the ordinary purchaser of houses would pay for. The experiment with the wooden boxes, which failed, seemed, therefore, a more practical one than that with the glass jars, as it more nearly represented the ordinary condition of things. The air would naturally follow the path of least resistance; and, unless the cupboards or drawers were made with the utmost accuracy, there would be chinks and openings much larger than those in the filtering materials would supply, and the air would probably prefer to pass that way rather than through the trap provided to catch the dust. In that very room might be found an example of what was done by the Society to exclude dirt and dust: the air which came through the grating along the wall was filtered through a fabric placed in the opening through which the air came; and it was astounding to see the amount of filth deposited on the fabric in three or four weeks. The screens, therefore, would constantly require cleaning, if they were to have any effect. He would suggest that, if the experiment with the glass jars were repeated, one should be left with no filter at all, so as to see the amount of dust deposited under ordinary circumstances. The small particles which were seen in the one covered with cotton wool were, very probably, in the jar before it was closed, or might have dropped from the cotton wool itself. He was not surprised at the thermometer between the double windows showing 30°, when one outside stood at 20°; probably one inside a room with a single window would have have shown about the same temperature.

Mr. W. SMARTT said some time since he placed an empty wine cask, carefully corked up, in an exposed position, and on examining it shortly afterwards found that a considerable quantity of water had got in. He concluded that the air inside had expanded and then contracted again, and sucked the water in;

it was no wonder, therefore, that air should make its way into drawers, &c., and carry dust with it. He suggested that the air chamber under the fire grate should have water placed in it, which would prevent the dust flying about; he had found this plan very effectual in a greenhouse fire. Many years ago, a system was devised by Sir Douglas Galton of dividing a chimney-flue longitudinally, and admitting pure air to the room through one half, which was at the same time warmed by the hot vapour in the other half; the plan had been employed in barracks, and he fancied effected considerable economy. If windows were made perfectly air-tight, he doubted whether sufficient oxygen for the purposes of health would be admitted to bedrooms.

Mr. WHITE said anyone who lived in London must feel grateful for an effort, which promised to be successful, in diminishing the dust nuisance which was the cause of an enormous expense to all householders. It was rather hard on architects, however, to have another obligation cast upon them, in addition to the multitude for which they were already held responsible. With regard to cupboards and presses, the only way of making them secure would be for some practical person to undertake the construction of dustproof receptacles, otherwise there would be little chance for many years to come, on account of the trouble and expense involved in keeping these strainers clean. If they were not regularly cleaned, perhaps once or twice a week, the whole effect would be lost. There could be no doubt that in the ventilation of a house, if a sufficient amount of air could be introduced at the upper part of a room, it would be so warmed before it came down to the lower part, that no draught would be felt, and this would facilitate permanent ventilation without the necessity for opening doors and windows, and so admitting dust. As to curing fogs, it was not by any means a simple matter. He understood that it was not merely the unconsumed carbon which polluted the air, but that the sulphurous and other chemical products held the carbon in suspension. At some future time it might be possible to disperse the fog by means of electricity, when it could be produced more cheaply. He was thoroughly convinced of the value of Mr. Teale's firegrates, and the closed chamber for the ash was really the key to the whole matter; being shut off from the cold air it became hot, and combustion was rendered much more perfect. The method of filling the chamber was introduced some 35 years ago by Mr. Moule, the inventor of the earth closet, and once he had the whole of the grates in his house fitted with them, but the result was to produce such an amount of heat that he gave it up rather than reduce the size of all the grates. No doubt the heat thus generated would do a great deal to consume smoke.

Mr. H. H. STATHAM confessed to feeling a little disappointed at not hearing something about what dust really was. Was it certain that a great deal of the dust did not arise in the rooms themselves, from the disintegration of various materials which was constantly going on. He did not like the idea of admitting air at the top of a room, because all the heated and vitiated air collected there, and the fresh air coming in would be contaminated with it. He should therefore prefer introducing it at a lower level, say four or five feet from the floor.

Mr. OLIVER J. WILLIAMS suggested that the glass in the double windows would, like air, contract and expand with variations in temperature, and that it would be well therefore to have some kind of spring for it to rest against. The double window system no doubt had many advantages, as those who had travelled in Russia well knew. An improved system of ventilation was much wanted, especially in London offices, where they suffered much from draughts, and which were very difficult to keep warm.

The CHAIRMAN, in proposing a vote of thanks to to Mr. Teale for his interesting and suggestive paper, said they all knew how dust abounded in London; and if they did not know exactly what it was, it seemed to increase with the introduction of wood pavement. In the West of England dust is called "pillum," and when a native of that part was asked what pillum was, he said, "Oh, to be sure, pillum is mucks a-dry." Then he was asked what mucks is, and his answer was, "Don't you know? mucks is pillum a-wet;" so he did not advance the matter further than other statements we have heard. Builders and workmen find it very difficult to change their traditional mode of construction, and it is necessary, therefore, to reiterate these instructive lessons contained in Mr. Teale's paper again and again, for the abundance of dust in London not only causes inconvenience, but is a source of serious injury to countless articles of value, as well as fabrics, furniture, and house decoration.

The vote of thanks having been carried unanimously,

Mr. TEALE, in reply, said he would admit that any contrivances such as he had described would need occasional care in cleaning; they would not continue to act automatically. Screened-in ventilators must be cleaned frequently, and in cupboards, &c., perhaps once a year, and renewed at longer intervals. It was also true that thoroughly good workmanship was necessary, but he thought the game was worth the candle; it was much better to catch all the dirt on a screen instead of having it on the papers or articles in the receptacle. Although it would not be possible to introduce these things universally, or even generally, there were conditions and positions where it would certainly be worth while; and if this investigation were undertaken by strictly scientific persons, young physicists, who would go into it in the same way as they did into bacteriology, and arrive at conclusions on which practical action could be based, it would be applied to the preservation of those beautiful things

to be found in most museums, which deteriorated so soon by dust. In the Leeds Museum there was a beautiful series of birds just put up. He could not say that he had yet found out how to keep the cases clean, but if they were having new ones made, they must insist on having perfect workmanship, and possibly would succeed in keeping out the dust. It was certainly an oversight not to have had one jar without any filtering material, but his object was to find the comparative value of the different materials, and in that he had succeeded. He should certainly continue the experiments, and should not forget Sir Henry Wood's suggestion, covering one jar simply with paper secured by an india-rubber band. He had never heard of Mr. Moule's suggestion with regard to putting water under the fire, but no doubt the effects attributed to the water were really due to there being a closed chamber. It was not necessary to damp the dust, because it fell into a closed space, and he feared that it would be so much trouble to keep the chamber filled with water that it would be impracticable. With regard to Sir Douglas Galton's plan of introducing warm air into a room, it might be useful in the case of large rooms which could not be kept warm by a good fire; but in rooms of ordinary size, such a device was not necessary, and it was much more comfortable and healthy to depend simply on the radiant heat of the fire. Mr. White had also raised the question of cost and trouble. He could only say, as he had more than once, that if he were beginning life, or had a son who was in want of a career and had mechanical tastes, he would set up a factory for making first-class fittings and furniture which would exclude dust, and he was quite sure in a few years he should do an enormous business. He hoped somebody would do it. He had quite enough to do with dust in its practical effects without going into the question of what it was; but he held the bulk of it in towns was soot; at any rate that was the mischievous part. Of course there was dust in country places from the roads and the sweepings of carpets, &c.; but this kind of dust, consisting of minute portions of texture, wood, &c., was not dirty dust; even in country houses the great nuisance arose from the super-added soot from the chimneys. After a fresh fall of snow, in a few hours quite a deposit of soot would be seen upon the surface; and he believed most people produced a great deal of the soot which went in at their own windows. The bulky particles did not travel very far; and he had seen, even in isolated country houses, quite a lot of soot on the window sills, which must have come there from the badly constructed fireplaces. Since he had altered his own fireplaces he found very little soot on his window sills or in the rooms. With regard to introducing air at the top of a room, he had adopted that plan for some years in his own consulting room, and found it answer perfectly; and another room, which he had ventilated for a friend, which was formerly very stuffy, was now quite comfortable, and the blacks had very much diminished. In another house where he had patients, he had ventilated several rooms in this way, and they were always fresh and wholesome. Foul air went to the top of a room under certain circumstances, but it was more or less stagnant, and the fresh air which came in under the doors and made your feet and legs cold went straight up the chimney without ventilating the room; but that admitted at the top circulated through the apartment. As a practical fact, air admitted in that way did make a room fresh, and did not produce a draught. Lastly, he might say that the cotton velvet, against which the glass was was pressed, acted practically as a kind of spring, and a careful joiner would put in the sprigs so as to keep the glass tight, and without any danger of breaking it.

Miscellaneous.

THE RAILWAYS OF BOLIVIA.

The Republic of Bolivia, with a population of 2,500,000, has an area of 55,000 square leagues, or 275,000 square kilomètres. Situated in the centre of the South American continent, it is bounded on the north and east by Brazil, on the south-east by the River Paraguay and the Republic of that name, on the south by the Argentine Republic, on the south-west by Chili, and on the west by the Pacific Ocean and Peru. The eastern part is level, as if it were a continuation of the Argentine pampas, which extend as far as the plains of Venezuela, forming forests, prairies, and fields of extraordinary tropical fertility. The western part is mountainous, and the Andes range, which forms this region, divides in latitude 22° south, and enters the Bolivian territory in two sections, the western or coast range, and the eastern or principal range. Between these two ranges is found the high Inter-Andine table-land, with an altitude of 12,000 to 13,000 feet above the level of the sea, at the northern end of which is situated the great Lake Titicaca, and towards the southern or central region, Lake Poopó, which receives the waters of the former by means of the River Desagnadero. This table-land is connected on the north with the plateaux of Puno in Peru, and on the south with those of the Argentine Republic. M. Juan F. Velarde, Bolivian delegate to the International American Railway Conference, says, in his report upon the railways of Bolivia, that the central position of that country has retarded the development of its railroads, since it has been obliged to wait until the lines of the neighbouring countries should approach its own frontiers before undertaking their extension, as in the case of those from Mollendo to Puno, and from Arica to Tacna, in Peru, which still remain idle within their respective limits, and that of the Central North Argentine Railway, which is now nearing Jujni, with every probability that it will be extended as far as the Bolivian frontier. Topographical and financial

difficulties for a long time prevented the construction of the railway from Antofagasta to the interior, but they have lately been overcome by the Huanchaca Company of Bolivia, which has succeeded in completing the narrow gauge railroad between Antofagasta and Uyuni, with an extent of 600 kilomètres (kilomètre = ·621 of a mile). The same company has contracted for the extension of this line to Oruro, a distance of 320 kilomètres. The configuration of the territory of Bolivia, and its vast area, gave origin to three channels of communication—by way of the Pacific, the River La Plata, and the Amazon respectively—each one of which is the outlet for a particular region, possessing resources of its own of great value, which will rapidly develop as soon as transportation is made cheap and easy, by the construction of railways. The communications by the Pacific are obtained—by Antofagasta Railway, by the Arica Railway, and by the Mollendo Railway. The Antofagasta Railway, which had to contend against the obstacles presented by an uninhabitable desert, has become practicable, on account of the narrow gauge railway which runs from that place to Uyuni. Uyuni is situated at a distance of 25 kilomètres from the rich mines of Huanchaca, 200 kilomètres from the city of Potosi, 300 kilomètres from the capital, and 320 kilomètres from Oruro. This line crosses a very rich mineral region of much promise. Its prolongation to Oruro, with a branch line to Potosi, will tend to further develop the mineral production. The Arica Railway runs a line as far as Tacna, whence it is intended to build another to Corocoro and La Paz. This work requires an immense capital, since the line has to ascend the coast range at its steepest part. This line is connected with the departments of La Paz, Oruro, and Cochabamba. The Mollendo railway, open to traffic since 1870, has the use of a line which leaves that port, runs through Areguipa, and ends in Puno, covering a distance of 522 kilomètres, or 320 miles. Bolivian traffic makes use of this railroad in connection with navigation by steamer on Lake Titicaca, and the high road from Chililaya to La Paz, 14 leagues. Concessions have been obtained from Peru, as well as from Bolivia, to extend this line as far as La Paz, whence, within a short time, a road will be run to Oruro, in order to form a junction there with the Antofagasta road. It is intended to run a branch line from Oruro to the fertile department of Cochabamba, a distance of 200 kilomètres. The Bolivian part of the railroad from Puno to La Paz extends 150 kilomètres from the Desaguadero. The Government guarantees 6 per cent. on the capital invested. The communications with the River La Plata are carried on by means of the Northern Central Argentine Railroad, and by the River Pasaguay and the high road to Santa Cruz. The extension of the Northern Central Argentine Railway has already reached Salta, and will go as far as Jujni, from which place it will be extended to the Bolivian frontier, the Argentine Government having granted a concession for this. It is proposed to run two railways from the River Paraguay—one from the Gaiva to Santa Cruz de la Sierra, running through the province of Chiquitos, over 750 kilomètres of level country, and another from Bahia Negra to Sucre, with a branch to Santa Cruz, 750 kilomètres in level country, and 500 kilomètres in mountainous and broken country. With these two railroads, and another contemplated, between Paraná and Tarja, communication will be opened with the River La Plata. The northern region of Bolivia, which is of wonderful fertility, and irrigated by the rivers Guaporé, Henes, Mamoré, Beni, and Madre de Dios, and their numerous navigable branches, which all unite to form the River Madera, the principal tributary of the Amazon, in order to enjoy the full benefits of steam navigation; and the products of civilisation requires, says M. Velarde, the construction of a railroad from the Madera to Mamoré, so as to avoid the rapids, which interfere with navigation on these great rivers; and this railway must be at least 180 miles long. The survey of this road has been in the hands of a commission of engineers appointed by the Brazilian Government, and its cost has been estimated at not more than 6,000,000 dollars in gold. In connection with this railway, and in order to make communication with the navigable rivers and the cities of the interior of Bolivia, it will be necessary to construct the following supplementary lines:—From Rio Grande, a tributary of the Mamoré, to Santa Cruz de la Sierra, 150 kilomètres through level country; from the River Chimoré, or Upper Mamoré, to Cochabamba, 250 kilomètres through broken and mountainous country; from the River Beni to La Paz, about 500 kilomètres, also through broken and mountainous country. Workmen, provisions, and timber, for the construction of these railways, are found in abundance in the respective departments of Santa Cruz, Cochabamba, and La Paz, which, it is said, will derive great benefit from them. In conclusion, M. Velarde says, "It is estimated that the freight on the materials for these railways, together with that on the steamers and machinery which will have to be imported for the rivers of Bolivia, outside of the regular traffic, will suffice to give life and impetus, for the first few years, to the Madera and Mamoré Railway, whose importance may be compared, without exaggeration, to that of the railway of the Isthmus of Panama."

General Notes.

CHICAGO EXHIBITION.—The Polytechnic Institution has published in pamphlet form a report of a lecture recently given at the Institution on Chicago and the Exhibition, by Mr. James Dredge. The pamphlet is fully illustrated, and includes information as to the Polytechnic cheap trips to Chicago.

JAPAN SOCIETY.—The first general meeting of the Japan Society was held in the hall of the Society of Arts, on Thursday afternoon, 28th January, with Francis Elgar, LL.D., in the chair. The Society has been formed for the encouragement of the study of the Japanese language, literature, history and folk-lore, of Japanese art, science and industries, of the social life and economic condition of the Japanese people, past and present, and of all Japanese matters. The Society will hold meetings, at which papers will be read, and discussions take place on the subjects interesting to those who have visited Japan, or who are concerned in that which relates to the natural products, topography, literature, arts, commerce, &c., of that country. The society will, by the aid of its members, arrange temporary loan exhibitions, illustrative of the arts, sciences, and industries of Japan, ancient and modern. "Transactions" and "Proceedings" will be published from time to time.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock :—

FEBRUARY 10.—E. PRICE EDWARDS, "Burning Oils for Lighthouses and Lightships." Sir LYON PLAYFAIR, K.C.B., F.R.S., will preside.

FEBRUARY 17.—Capt. F. E. YOUNGHUSBAND, "The Pamirs."

FEBRUARY 24.—ERNEST HART, "Ancient and Modern Art Pottery of Japan." Prof. WILLIAM ANDERSON, F.R.C.S., will preside.

MARCH 2.—Prof. VIVIAN B. LEWES, "Spontaneous Ignition of Coal, and its Prevention."

MARCH 9.—A. P. LAURIE, M.A., "Experiments on the Durability of Modern Pigments."

MARCH 16.—TEMPEST ANDERSON, M.D., "Iceland."

MARCH 23.—GILBERT R. REDGRAVE, "Manufacture and Industrial Application of Flexible Tubing."

FOREIGN AND COLONIAL SECTION.

Tuesdays, at Half-past Four or Eight o'clock; due notice of the hour will be given :—

FEBRUARY 16.—LEWIS ATKINSON, "The Forthcoming Exhibition at Kimberley." The Hon. JOHN X. MERRIMAN, M.L.A., will preside. The paper will be illustrated by lantern slides. 8 p.m.

MARCH 15.—F. A. PEZET (Peruvian Consul General), "Peru." 8 p.m.

APRIL 5.—The Rev. JOHN MCLEAN, D.D. "Manitoba and the North-West Provinces of the Dominion."

APRIL 26.—Sir EDWARD BRADDON, K.C.M.G., "The Progress of Australasia."

MAY 24.—Colonel HOWARD VINCENT, C.B., M.P., "The Extension of Colonial Trade."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m. :—

FEBRUARY 11.—LORD LAMINGTON, "Recent Travels in Indo-China: From Siam to Tonquin." Lieut.-General Sir ANDREW CLARKE, G.C.M.G., C.B., C.I.E., will preside. The paper will be illustrated by lantern slides.

MARCH 3.—Surgeon-General Sir WILLIAM JAMES MOORE, K.C.I.E., "Indian Sanitation and the International Congress of Hygiene." Major-Gen. Sir OWEN TUDOR BURNE, K.C.S.I., C.I.E., will preside.

MARCH 24.—G. H. M. BATTEN, formerly of the Bengal Civil Service, "The Opium Question." Sir JOHN STRACHEY, G.C.S.I., C.I.E., will preside.

APRIL 7.—Dr. J. AUGUSTUS VOELCKER, "The Agricultural Needs of India."

APRIL 28.—Sir WILLIAM WEDDERBURN, Bart., "Reorganisation of Agricultural Credit in India." The Right Hon. Sir JAMES CAIRD, K.C.B., will preside.

MAY 19.—JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock :—

FEBRUARY 23.—J. WILLIAM TONKS, "Artistic Treatment of Jewellery: Jewel and Address Caskets." Sir PHILIP CUNLIFFE-OWEN, K.C B., K.C.M.G., C.I.E., will preside.

MARCH 29.—E. ROSCOE MULLINS, "The Decorative Uses of Sculpture." ALFRED GILBERT, A.R.A., will preside.

APRIL 12.—C. PURDON CLARKE, C.I.E., "English Brocades and Figured Silks."

MAY 17.—GEORGE J. ROBINSON, "Decorative Plaster Work" (II.). J. HUNGERFORD POLLEN will preside.

CANTOR LECTURES.

Monday evenings, at Eight o'clock :—

PROF. GEORGE FORBES, F.R.S., "Developments of Electrical Distribution." Four Lectures.

LECTURE III.—FEBRUARY 8.—Transmission and distribution of electricity derived from lighting

circuits—Effect on load factor—Separate circuits for power—Distribution for street and other railways—Utilisation of water-power by electric transmission to a distance.

LECTURE IV.—FEBRUARY 15.—Generators of electricity by water-power and by steam obtained from destructors—General account of destructors—Hydraulic accumulators—Utilisation of local circumstances—Probable developments of electric distribution in the immediate future.

PROF. WILLIAM ROBINSON, M.E., Assoc-M.Inst.C.E., "The Uses of Petroleum in Prime Movers." Four Lectures.
February 29, March 7, 14, 21.

BENNETT H. BROUGH, "Mine Surveying." Three Lectures.
March 28, April, 4, 11.

DR. PERCY FRANKLAND, F.C.S., "Recent Contributions to the Chemistry and Bateriology of the Fermentation Industries." Four Lectures.
May 2, 9, 16, 23.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 8... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Prof. George Forbes, "Developments of Electrical Distribution." (Lecture III.)
Geographical, 44, Brown-street, Manchester. Prof. Boyd Dawkins, "Geology in relation to Geography."
Geographical, University of London, Burlington-gardens, W., 8½ p.m.
British Architects, 9, Conduit-street, W., 8 p.m. Mr. Edwin T. Hall, "Building Legislation."
Medical, 11, Chandos-street, W., 8½ p.m.
London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Henry Power, "The Movements of the Body, and how they are accomplished."

TUESDAY, FEB. 9... Royal Institution, Albemarle-street, W., 3 p.m. Professor Victor Horsley, "The Brain." (Lecture IV.)
Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.
Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Alfred Harper Curtis, "Gold-Quartz Reduction."
Photographic, 5A, Pall-mall East, S.W., 8 p.m. Annual Meeting.
Anthropological, 3, Hanover-square, W., 8½ p.m. 1. Mr. M. J. Walhouse, "Exhibition of Articles and Implements of every-day use among the Chin Tribes, on the Burmese Frontier." 2. Captain E. S. Hastings, "Exhibition of the Skull of a Chin Dacoit Leader." 3. Mr. J. R. Mortimer, "Exploration of Howe-hill Barrow, Duggleby, Yorkshire." 4. Dr. J. G. Garson, "Human Remains found in Howe-hill Barrow."
Colonial Institute, Whitehall Rooms, Hotel Métropole, Whitehall-place, S.W., 8 p.m. The Rev. Canon Beanlands, "British Columbia: a Problem of Colonial Development."

WEDNESDAY, FEB. 10... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. E. Price Edwards, "Burning Oils for Lighthouses and Lightships."
Geological, Burlington-house, 8 p.m. 1. Prof. J. Prestwich, "The Raised Beaches, 'Head,' or Rubble Drift in the South of England: their relation to the Valley Drifts and to the Glacial Period." 2. Messrs. B. N. Peach and John Horne, "The *Oleuellus* Zone in the North-West Highlands of Scotland."
Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m.
Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m.

THURSDAY, FEB. 11... SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Lord Lamington, "Recent Travels in Indo-China."
Royal, Burlington-house, W., 4½ p.m.
Antiquaries, Burlington-house, W., 8½ p.m.
London Institution, Finsbury-circus, E.C., 7 p.m. Mr. William H. Cummings, "19th Century Music" (with vocal and instrumental illustsations).
Royal Institution, Albemarle-street, W., 3 p.m. Prof. E. Ray Lancaster, "Some Recent Biological Discoveries."
Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on papers by Mr. Alexander Siemens "Some Experimental Investigations of Alternate Currents," and Mr. W. H. Preece, "The Specification of Insulated Conductors for Electric Lighting and other purposes."
Institute of Architecture, Science, and Art, Dundee, 8 p.m. Mr. John Honeyman, "Glasgow Cathedral."
Mathematical, 22, Albemarle-street, W., 8 p.m.
Photographic Club, Anderton's Hotel, Fleet-street, E.C., 8 p.m. Mr. A. Haddon, "Glass Blowing for the Laboratory."

FRIDAY, FEB. 12... United Service Institution, Whitehall-yard, 3 p.m. Vice-Admiral Sir Edmund Fremantle, "The Training of our Seamen."
Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m. Mr. G. J. Symons, "Rain, Snow, and Hail."
Civil Engineers, 25, Great George-street, S.W., 7½ p.m. (Students' Meeting.) Mr. H. B. Ransom, "Fly-Wheels and Governors."
Astronomical, Burlington-house, W., 8 p.m.
Junior Engineering Society, Westminster-palace-hotel, W., 8 p.m. Mr. Ernest G. Walker, "The Gas Engine."
Clinical, 20, Hanover-square, W., 8½ p.m.

SATURDAY, FEB. 13... Saturday Lecture Society, Lecture Theatre, South Kensington Museum, S.W., 3 p.m. Rev. G. F. Browne, "Early Christian Art." (Lecture I.—Ireland.)
Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.
Royal Institution, Albemarle-street, W., 3 p.m. Lord Rayleigh, "Matter: at Rest and in Motion." (Lecture I.)

CORRECTION.—Figures 1 and 3 in Dr. Edridge-Green's paper, on "Lovibond's Tintometer," were inadvertently misplaced in the last number of the *Journal* (pp. 214, 216). Figure 1 is absorption curve of the yellow glass, and should be numbered figure 3; figure 3 is absorption curve of the rose glass, and should be numbered figure 1.

Journal of the Society of Arts.

No. 2,047. Vol. XL.

FRIDAY, FEBRUARY 12, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CANTOR LECTURES.

Prof. George Forbes, F.R.S., delivered the third lecture of his course on "Developments of Electrical Distribution," on Monday evening, 8th inst. The lectures will be printed in the *Journal* during the summer recess.

Chicago Exhibition, 1893.

INDIA COMMITTEE.

A meeting of the India Committee was held on Thursday, at the offices of the Society of Arts. Present: Major-General Sir Owen Tudor Burne, K.C.S.I., C.I.E. (Chairman of the Committee); Lionel Robert Ashburner, C.S.I., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., General Sir George Chesney, K.C.B., C.S.I., C.I.E., S. Digby, William Digby, C.I.E., Colonel C. L. O. FitzGerald, C.B., W. S. Halsey, Robert Hardie, Charles Malcolm Kennedy, C.B., Lieut.-General J. Michael, C.S.I., Dadabhai Naoroji, Charles Pontifex, Lesly C. Probyn, Vincent J. Robinson, C.I.E., Alexander Rogers, Thomas H. Thornton, C.S.I., D.C.L., Stephen Wheeler, Sir Alexander Wilson, and Sir Henry Trueman Wood, Secretary of the Royal Commission.

Under date of the 27th August, 1891, Her Majesty was pleased to issue a Commission to the Council of the Society of Arts, authorising them to act as Commissioners for the Universal Exhibition, which, pursuant to an Act of Congress, and in accordance with a Proclamation made by the President of the United States of America, will be held at Chicago from May 1st to October 30th, 1893.

The Royal Commission are now prepared to receive applications from artists, manufacturers, and others desirous of taking part in the Exhibition, to afford them all necessary information, and to offer them all available facilities which they may desire for this purpose.

Such applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, not later than February 29th, 1892, and addressed to the Secretary, as above.

As the funds granted by H.M. Government will not suffice to defray all the expenses of the Section, it is necessary that they should be supplemented by payments from the exhibitors. A charge will therefore be made to each exhibitor, based on the amount of space occupied, and calculated on the following scale:—

	Per sq. ft. s.	d.
For spaces not exceeding 100 sq. ft. ..	5	0
For spaces exceeding 100 sq. ft. and not exceeding 200 sq. ft.	4	6
For spaces exceeding 200 sq. ft. and not exceeding 300 sq. ft.	4	0
For spaces exceeding 300 sq. ft. and not exceeding 500 sq. ft.	3	6
For spaces exceeding 500 sq. ft. and not exceeding 750 sq. ft.	3	0
For spaces exceeding 750 sq. ft. and upwards	2	6

The minimum charge will be £5.

It is not expected that the total receipts from all sources will more than suffice to defray the cost of an adequate representation of British industry; but should there be a sufficient surplus after the payment of all the costs of the Section, the Royal Commission will refund the balance *pro rata* with the amounts contributed by the several exhibitors. The amount produced by the payments of exhibitors will therefore be treated as a guarantee fund, to be expended if necessary, but if not, to be refunded to the contributors.

The Exhibition is situated in Jackson-park, within the southern limits of the city of Chicago. The principal buildings are devoted to the following main divisions:—(1) Fine Arts; (2) Manufactures and Liberal Arts; (3) Agricul-

ture; (4) Machinery; (5) Electricity; (6) Mines; (7) Transportation; (8) Horticulture. In all these, space has been allotted to Great Britain, though it is expected that the principal British Court will be that in the Building of Manufactures and Liberal Arts, since the privilege has been conceded to this country of massing all or most of its exhibits together, should such a course prove desirable.

Exhibitors' goods will be transmitted direct in bond to Chicago, where the usual Customs examination will be made. Goods for exhibition only will not be liable to duty, but on goods sold the usual rates will have to be paid. Goods can be sold in bond, at prices independent of the tariff, the duties being payable by the purchaser.

The American railroad companies propose to carry goods back from the Exhibition free, charging the usual rates for the outgoing journey. These rates, it may be noted, are low in comparison with those usual in European countries. It is hoped that special terms for Exhibition goods traffic may be obtained from the Atlantic steamship companies. Full information as to routes, traffic, rates, &c., will be provided in due course.

A general Official Catalogue will be published in English, French, German, and Spanish. A special catalogue will also be published for the British Section.

Exhibitions of live stock will be held, and prizes will be offered in connection with them. A special circular has been issued, giving information about these.

A limited quantity of steam and water power will be supplied gratuitously. Further supplies will be provided at a fixed rate. Countershafts, pulleys, belts, &c., must be provided by the exhibitor. Application for motive power must be made on special forms, which will be supplied on demand.

The general reception of articles at the Exhibition buildings will commence on November, 1892, and no articles will be admitted after April 10, 1893. Foundations for heavy machinery may be put in, and special constructive work commenced, as soon as the state of the grounds and the buildings permits.

Special regulations will be hereafter issued for the organisation of the International Juries.

The Royal Commission are informed that the contract labour laws of the United States will not prevent exhibitors from importing foreign labour, or from entering into binding contracts with their *employés*. Further information on this head will be supplied on application.

Every person who becomes an exhibitor in the British Section thereby agrees to be governed by the rules and regulations laid down by the Exhibition Executive, or by the Royal Commission through its executive officer.

Proceedings of the Society.

APPLIED ART SECTION.

Tuesday, January 26th, 1892; Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., LL.D., M.D., Vice-President of the Society, in the chair.

The CHAIRMAN, in opening the proceedings, said:—Mr. William Morris needs no introduction to any English audience. But before he addresses you I must in a few words express my sense, and I am sure the sense of every one present, of the high honour he has done us in coming here this evening to open the sixth session of the Applied Art Section of the Society of Arts. It is not only as a poet and an art critic that he is one of the first Englishmen of the Victorian age. When the decorative arts of this country had about the middle of the present century gradually become denationalised, it was Mr. William Morris

"Who stemm'd the torrent of a downward age,"

and by the vigour of his characteristic English genius, cultivated in every phase of its activity to the highest sensibility, upraised these household arts again from the degradation of nearly two generations, and carried them to a perfection never before reached by them. And the influence of this, his distinctive work, will not die with him, for already he has succeeded in founding a national school of decorative designers, who, like Mr. Walter Crane and Mr. Lewis Day, approve his teaching to the judgment of their contemporaries, not by imitating his individual style and manner, but by faithfully following his example in seeking in English nature the ever quickening inspiration of English art. The way was, indeed, made straight before Mr. Morris and his followers by the revival in our national building style initiated by Pugin between 1837 and 1857. Owen Jones was the first to respond, as a designer, to the new impulse. But from his studies of the Alhambra and the overpowering impression made on him by the arts of India at the Great Exhibition of 1861, his mind became supersaturated with Orientalism, of which he and his best disciples remained, to the last, the slavish imitators. This has invariably led, in the history of Western art, to that repulsive vulgarisation of ornament, and that overloading with it of all forms, even architectural, which we indicate by

the term "rococo." We were saved from such a result in this century, at just the critical moment, by Mr. William Morris. A born decorator, he knew that it is decoration that animates architecture, and all form, with life and beauty. But being also a trained architect, he from the first recognised that ornament was but an accessory to construction of every kind, from the vessels turned on a potter's wheel to the grandest creations of the builders master art. Thus, and by his commanding intellectual and moral personal influence with his contemporaries, the future of English decorative design, in all its applications, was redeemed by Mr. Morris. I feel altogether unworthy of offering this expression of my appreciation of Mr. Morris's universally recognised claims on the consideration of his countrymen, but in receiving him here this evening I have felt it my duty to deliberately say what I have, on behalf of the Applied Art Section of the Society of Arts, for permanent record in the Society's *Journal*.

The paper read was—

THE WOODCUTS OF GOTHIC BOOKS.

By William Morris.

I shall presently have the pleasure of showing you in some kind of sequence a number of illustrations taken from books of the 15th and first years of the 16th centuries. But before I do so I wish to read to you a few remarks on the genesis and the quality of the kind of art represented by these examples, and the lessons which they teach us.

Since the earliest of those I have to show is probably not earlier in date than about 1420, and almost all are more than fifty years later than that, it is clear that they belong to the latest period of Mediæval art, and one or two must formally be referred to the earliest days of the Renaissance, though in spirit they are still Gothic. In fact, it is curious to note the suddenness of the supplanting of the Gothic by the neo-classical style in some instances, especially in Germany: *e.g.*, the later books published by the great Nuremberg printer, Koberger, in the fourteen-nineties, books like the "Nuremberg Chronicle," and the "Schatzbehalter," show no sign of the coming change, but ten years worn, and hey, presto, not a particle of Gothic ornament can be found in any German printed book, though, as I think, the figure-works of one great man, Albert Durer, were Gothic in essence.

The most part of these books, in fact all of them in the earlier days (the exceptions being mainly certain splendidly ornamented French books, including the sumptuous books of "Hours"), were meant for popular books: the great theological folios, the law books, the decretals, and such like of the earlier German printers, though miracles of typographical beauty, if ornamented at all, were ornamented by the illuminator, with the single exception of Gutenburg's splendid "Psalter," which gives us at once the first and the best piece of ornamental colour-printing yet achieved. Again, the dainty and perfect volumes of the classics produced by the earlier Roman and Venetian printers disdained the help of wood blocks, though they were often beautifully illuminated, and it was not till after the days of Jenson, the Frenchman who brought the Roman letter to perfection, it was not till Italian typography began to decline, that illustration by reproducible methods became usual; and we know that these illustrated books were looked upon as inferior wares, and were sold far cheaper than the unadorned pages of the great printers. It must be noted in confirmation of the view that the woodcut books were cheap books, that in most cases they were vernacular editions of books already printed in Latin.

The work, then, which I am about to show you has first the disadvantage of the rudeness likely to disfigure cheap forms of art in a time that lacked the resource of slippery plausibility which helps out cheap art at the present day. And secondly, the disadvantage of belonging to the old age rather than the youth or vigorous manhood of the Middle Ages. On the other hand, it is art, and not a mere trade "article;" and though it was produced by the dying Middle Ages, they were not yet dead when it was current, so that it yet retains much of the qualities of the more hopeful period; and in addition, the necessity of adapting the current design to a new material and method gave it a special life, which is full of interest and instruction for artists of all times who are able to keep their eyes open.

All organic art, all art that is genuinely growing, opposed to rhetorical, retrospective, or academical art, art which has no real growth in it, has two qualities in common: the epical and the ornamental; its two functions are the telling of a story and the adornment of a space or tangible object. The labour and ingenuity necessary for the production of anything that claims our attention as a work of art are wasted, if they are employed on anything else than these two aims. Mediæval art, the result of a long unbroken series of tradition, is preeminent for its grasp of these two functions, which, indeed, interpenetrate then more than

in any other period. Not only is all its special art obviously and simply beautiful as ornament, but its ornament also is vivified with forcible meaning, so that neither in one or the other does the life ever flag, or the sensuous pleasure of the eye ever lack. You have not got to say, Now you have your story, how are you going to embellish it? Nor, Now you have made your beauty, what are you going to do with it? For here are the two together, inseparably a part of each other. No doubt the force of tradition, which culminated in the Middle Ages, had much to do with this unity of epical design and ornament. It supplied deficiencies of individual by collective imagination (compare the constantly recurring phrases and lines in genuine epical or ballad poetry); it ensured the inheritance of deft craftsmanship and instinct for beauty in the succession of the generations of workmen; and it cultivated the appreciation of good work by the general public. Now-a-days artists work essentially for artists, and look on the ignorant layman with a contempt, which even the necessity of earning a livelihood cannot force them wholly to disguise. In the times of art, they had no one but artists to work for, since everyone was a potential artist.

Now, in such a period, when written literature was still divine, and almost miraculous to men, it was impossible that books should fail to have a due share in the epical-ornamental art of the time. Accordingly, the opportunities offered by the pages which contained the wisdom and knowledge of past and present times were cultivated to the utmost. The early Middle Ages, beginning with the wonderful caligraphy of the Irish MSS., were, above all times, the epoch of *writing*. The pages of almost all books, from the 8th to the 15th century, are beautiful, even without the addition of ornament. In those that are ornamented without pictures illustrative of the text, the eye is so pleasured, and the fancy so tickled by the beauty and exhaustless cheerful invention of the illuminator, that one scarcely ventures to ask that the tale embodied in the written characters should be further illustrated. But when this is done, and the book is full of pictures, which tell the written tale again with the most conscientious directness of design, and as to execution with great purity of outline and extreme delicacy of colour, we can say little more than that the only work of art which surpasses a complete Mediæval book is a complete Mediæval building. This must be said, with the least qualification, of the books of from about 1160 to 1300. After this date, the work loses, in purity and simplicity, more than it gains in pictorial qualities, and, at last, after the middle of the 15th century, illuminated books lose much of their individuality on the ornamental side; and, though they are still beautiful, are mostly only redeemed from commonplace when the miniatures in them are excellent.

But here comes in the new element, given by the invention of printing, and the gradual shoving out of the scribe by the punch-cutter, the typefounder, and the printer. The first printed characters were as exact reproductions of the written ones as the new craftsmen could compass, even to the extent of the copying of the infernal abbreviations which had gradually crept into manuscript; but, as I have already mentioned, the producers of serious books did not at first supply the work of the illuminator by that of the woodcutter, either in picture work or ornament. In fact the art of printing pictures from wood blocks is earlier than that of printing books, and is undoubtedly the parent of book illustration. The first woodcuts were separate pictures of religious subjects, circulated for the edification of the faithful, in existing examples generally coloured by hand, and certainly always intended to be coloured. The earliest of these may be as old as 1380, and there are many which have been dated in the first half of the 15th century; though the dates are mostly rather a matter of speculation. But the development of book illustration proper by no means put an end to their production. Many were done between 1450 and 1490, and some in the first years of the 16th century; but the earlier ones only have any special character in them. Of these, some are cut rudely and some timidly also, but some are fairly well cut, and few so ill that the expression of the design is not retained. The design of most of these early works is mostly admirable, and as far removed from the commonplace as possible; many, nay most of these cuts, are fine expressions of that passionate pietism of the Middle Ages which has been somewhat veiled from us by the strangeness, and even grotesqueness which has mingled with it, but the reality of which is not doubtful to those who have studied the period without prejudice. Amongst these may be cited a design of Christ being pressed in the wine press, probably as early as the end of the 14th century, which may stand without disadvantage beside a fine work of the 13th century.

FIG. 1.—FLEMISH SCHOOL. FROM "THE LIFE OF CHRIST." ANTWERP: GHERAERT LEEUW, 1487.
[Size of Original.]

The next step towards book illustration brings us to the block-books, in which the picture-cuts are accompanied by a text, also cut on wood; the folios being printed by rubbing off on one side only. The subject of the origin of the most noteworthy of these books, the "Ars Moriendi," the "Lord's Prayer," the "Song of Solomon," the "Biblia Pauperum," the "Apocalypse," and the "Speculum Humanæ Salvationis," has been debated, along with the question of the first printer by means of moveable types, with more acrimony than it would seem to need. I, not being a learned person, will not add one word to the controversy; it is enough to say that these works were done somewhere between the years 1430 and 1460, and that their style was almost entirely dominant throughout the Gothic period in Flanders and Holland, while it had little influence on the German wood-cutters. For the rest, all these books have great merit as works of art; it would be difficult to find more direct or more poetical rendering of the events given than those of the "Speculum Humanæ Salvationis;" or more elegant and touching designs than those in the "Song of Solomon." The cuts of the "Biblia Pauperum" are rougher, but full of vigour and power of expression. The "Ars Moriendi" is very well drawn and executed, but the subject is not so interesting. The "Apocalypse" and the "Lord's Prayer" are both of them excellent, the former being scarcely inferior in design to the best of the Apocalypse picture MSS. of the end of the 13th century.

We have now come to the wood-cuts which ornament the regular books of the Gothic period, which began somewhat timidly. The two examples in Germany and Italy, not far removed from each other in date, being the "Historie von Joseph, Daniel, Judith, and Esther," printed by Albrecht Pfister, at Bamberg, in 1462; and the "Meditations of Turrecremata (or Torquemada)," printed at Rome by Ulric Hahn, in the year 1467, which latter, though taken by the command of the Pope from the frescoes of a Roman Church (Sta. Maria Sopra Minerva) are as German as need be, and very rude in drawing and execution, though not without spirit.

But, after this date, the school of wood-carving developed rapidly; and, on the whole, Germany, which had been very backward in the art of illumination, now led the new art.

The main schools were those of Ulm and Augsburg, of Maintz, of Strasburg, of Basel, and of Nuremburg, the latter being the later. The examples which I shall presently have the pleasure of showing you are wholly of the first and the last, as being the most representative, Ulm and Augsburg of the earlier style, Nuremburg of the later. But I might mention, in passing, that some of the earlier Basel books, notably Bernard Richel's "Speculum Humanæ Salvationis," are very noteworthy; and that, in the fourteen-eighties, there was a school at Maintz that produced, amongst other books, a very beautiful "Herbal," and Breydenbach's "Peregrinatio," which, amongst other merits, such as actual representations of the cities on the road to the Holy Land, must be said to contain the best executed woodcuts of the Middle Ages. Of course, there were many other towns in Germany which produced illustrated books, but they may be referred in character to one or other of these schools.

In Holland and Flanders there was a noble school of wood-cutting, delicately decorative in character, and very direct and expressive, being, as I said, the direct descendant of the block-books. The name of the printer who produced most books of this school was Gerard Leeuw (or Lion), who printed first at Gouda, and afterwards at Antwerp. But Colard Mansion, of Bruges, who printed few books, and was the master of Caxton in the art of printing, turned out a few very fine specimens of illustrated books. One of the most remarkable illustrated works published in the Low Countries—which I mention for its peculiarity—is the "Chevalier Deliberé" (an allegorical poem on the death of Charles the Rash), and I regret not being able to show you a slide of it, as it could not be done satisfactorily. This book, published at Schiedam in 1500, decidedly leans towards the French in style, rather than the native manner deduced from the earlier block-books.

France began both printing and book illustration somewhat late, most of its important illustrated works belonging to a period between the years 1485 and 1520; but she grasped the art of book decoration with a firmness and completeness very characteristic of French genius; and, also, she carried on the Gothic manner later than any other nation. For decorative qualities, nothing can excel the French books, and many of the picture-cuts, besides their decorative merits, have an additional interest in the romantic quality which they introduce: they all look as if they might be illustrations to the "Morte D'Arthur" or "Tristram."

In Italy, from about 1480, onward book

illustrations became common, going hand-in-hand with the degradation of printing, as I said before. The two great schools in Italy are those of Florence and Venice. I think it must be said that, on the whole, the former city bore away the bell from Venice, in spite of the famous Aldine "Polyphilus," the cuts in which, by the way, are very unequal. There are a good many book illustrations published in Italy, I should mention, like those to Ulric Hahn's "Meditations of Turrecremata," which are purely German in style; which is only to be expected from the fact of the early printers in Italy being mostly Germans.

I am sorry to have to say it, but England cannot be said to have a school of Gothic book illustration; the cuts in our early printed books are, at the best, French or Flemish blocks pretty well copied; at the worst, they are very badly copied. This lamentable fact is curious, considered along with what is also a fact: that in the 13th and 14th centuries the English were, on the whole, the best book decorators.

I have a few more words to say yet on the practical lessons to be derived from the study of these works of art; but before I say them, I will show you, by your leave, the slides taken from examples of these woodcuts. Only I must tell you first, what doubtless many of you know, that these old blocks were not produced by the graver on the end section of a piece of fine-grained wood (box now invariably), but by the knife on the plank section of pear-tree or similar wood—a much more difficult feat when the cuts were fine, as, *e.g.*, in Lützelberger's marvellous cuts of the "Dance of Death."

Mr. Morris then showed a series of lantern slides, which he described as follows:—

1. This is taken from the "Ars Moriendi," date about 1420. You may call it Flemish or Dutch, subject to raising the controversy I mentioned just now.

2. The "Song of Solomon," about the same date.

3. From the first illustrated book of the Ulm school. The Renowned and Noble Ladies of Boccaccio. It begins with Adam and Eve. The initial letter is very characteristic of the Ulm school of ornament. The trail of the serpent forms the S, and in the knots of the tail are little figures representing the seven deadly sins.

4. Another page from the same book. "Ceres and the Art of Agriculture." One of the great drawbacks to wood block printing in those times was the weakness of the presses. Their only resource was to print with the paper very wet, and with very soft packing, so that the block went well into the paper; but many books, and this amongst others, have suffered much from this cause.

5. Another page of the same book. The date is 1473.

6. This is from an Augsburg book. "Speculum Humanæ Vitæ," written by a Spanish bishop, which was a great favourite in the Middle Ages. It gives the advantages and disadvantages of all conditions of life. This block contains a genealogical tree of the Hapsburg family, and is an exceedingly beautiful piece of ornamental design very well cut.

7. From the same book; representing not the "Five Alls," with which you are familiar, but the "Four Alls; the gentleman, the merchant, the nobleman, and the poor man, who is the support of the whole lot, with his toes coming through his shoes. This is a fine specimen of the printing of Gunther Zeiner. The initial letters are very handsome in all these Augsburg books.

8. There is a picture of the Unjust Lawyer, from the same book, taking money from both sides. The date of this book is about 1475.

9. From "Æsop's Fables," a reproduction of the "Ulm Æsop," by Antony Sorg, of Augsburg (but the pictures are printed from the same blocks), the "Fly on the Wheel," and the "Jackdaw and Peacock." These designs for the Æsop pictures went all through the Middle Ages, with very little alteration.

10. "King Stork and King Log," from the same book.

11. This is from the Fable-book of Bidpay, by Conrad Dinckmuth, who carried on the early glories of the Ulm school in a later generation; about 1486.

12. The Parrot in a Cage, with the ladies making a sham storm to cause the poor bird to be put to death. Dinckmuth did some very remarkable work: one of the best of which was a German translation of the "Eunuchus" of Terence; another the "Chronicle of the Swabians."

13. The "Schatzbehalter," published by Koburger, of Nuremburg; 1491. Although so late, there is no trace of any classical influence in the design. The architecture, for instance, is pure late German architecture.

14. From the same book, "Joshua Meeting the Angel," and "Moses at the Burning Bush."

FIG. 2.—FRENCH SCHOOL. FROM "LA MER DES HISTOIRES." PARIS: PIERRE LE ROUGE, 1488.
[Size of Original, 10 in. by 14⅝ in.]

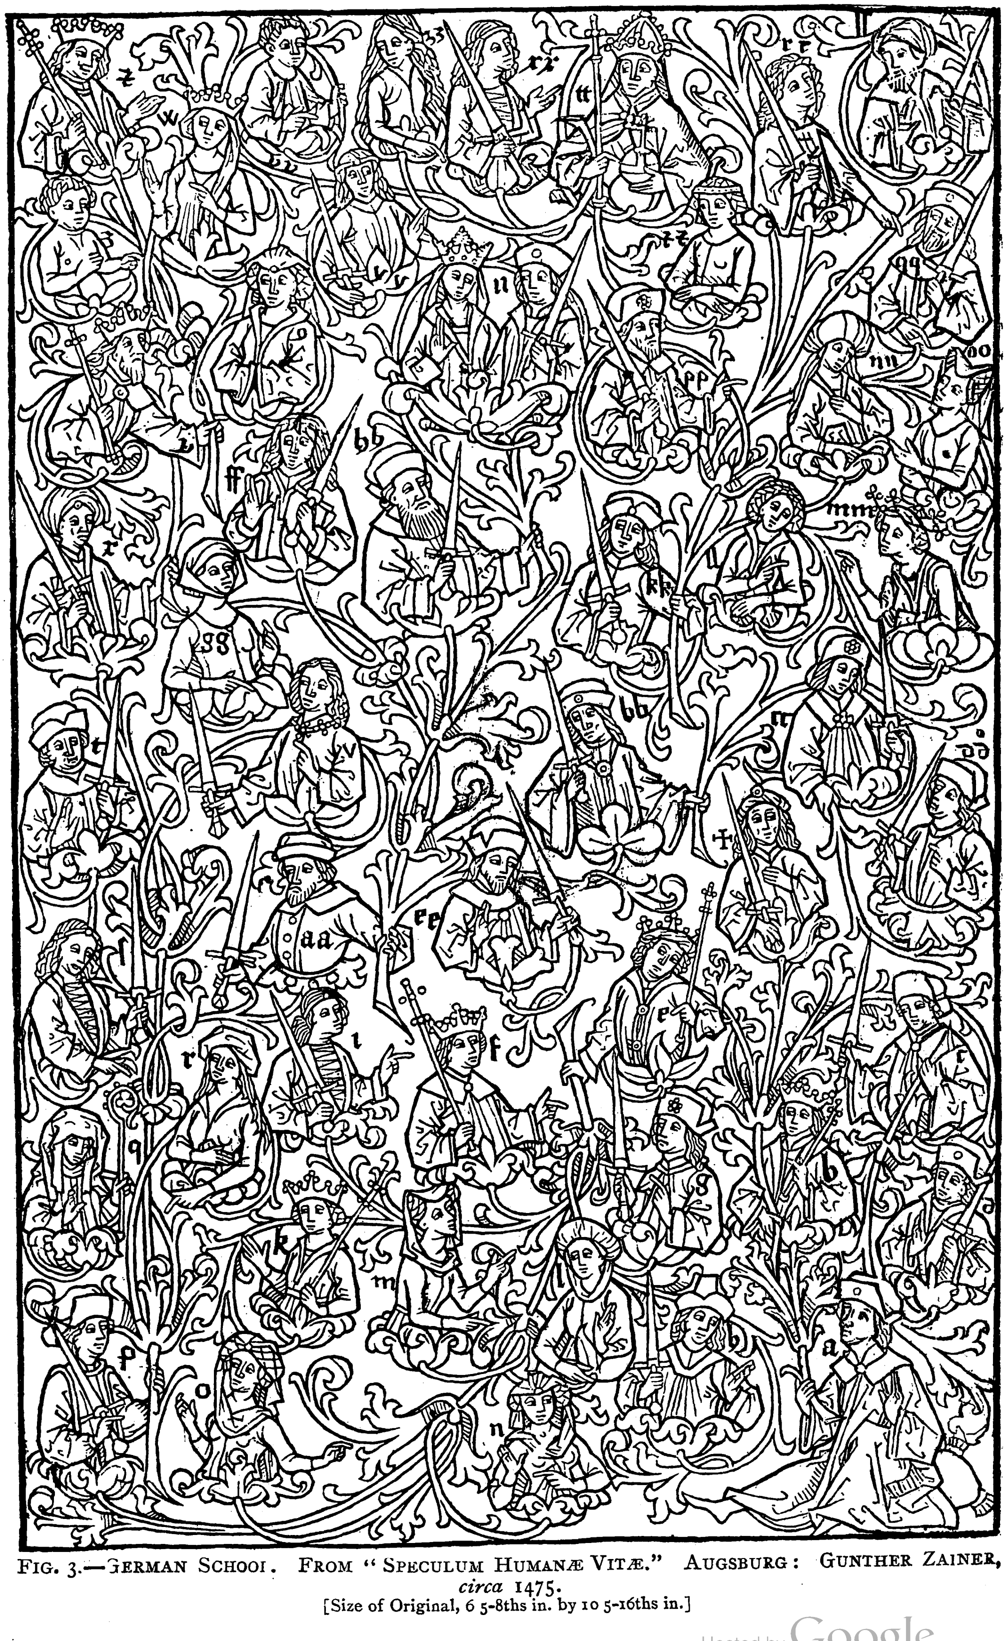

FIG. 3.—GERMAN SCHOOL. FROM "SPECULUM HUMANÆ VITÆ." AUGSBURG: GUNTHER ZAINER, *circa* 1475.

[Size of Original, 6 5-8ths in. by 10 5-16ths in.]

15. A page, or part of a page, from the celebrated *Nuremberg Chronicle*, printed by Koburger in 1493. This is in a way an exception to the rule of illustrated books being in the vernacular, as it is in Latin; but there is also a German edition.

16. Another specimen of the same book.

17. From a curious devotional book, "Der Seusse," printed by Antony Sorg, at Augsburg; about 1485,

18. Another page, which shows the decorative skill with which they managed their diagram pictures.

19. An example of the Flemish school, and characteristic of the design of white on black, which is so often used both by the Florentine and the Flemish wood-cutters. It is from a life of Christ, published by Gerard Leeuw in 1487.

20. Another page from the same book. There are certainly two artists in this book, and the one on the left appears to be the more pictorial of the two; though his designs are graceful, he is hardly as good as the rougher book illustrator. Gerard Leeuw had a very handsome set of initial letters, a kind of ornament which did not become common until after 1480.

21. Another one from the same book.

22. From another Flemish book, showing how the style runs through them all. St. George and the Dragon; from "A Golden Legend," 1503.

23. One of French series, from a very celebrated book called "La Mer des Histoires." It begins the history of France a little before the deluge. It is a most beautiful book, and very large. One would think these borders were meant to be painted, as so many "Books of Hours" were, but I have never seen a copy which has had the borders painted, though, as a rule, when the borders are meant to be painted, it is not common to find one plain.

24. Another page from the same book; but the slide does not do justice to it. I will here mention that one failing of the French publishers was to make one picture serve for several purposes. The fact is, they were more careful of decoration than illustration.

25. Another French book by a French printer, the "Aubre des Batailles," which illustrates that curious quality of romance which you find in the French pictures. It is true that many of these cuts were not made for this book; in fact, they were done for another edition of the Chevalier Deliberé, the Flemish edition of which I have mentioned before, for some have that name on them.

26. Another from the same book.

27. Another good example of the French decorative style. It is from Petrarch's "Remedy of either Fortune." This is the author presenting his book to the king, and is often used in these French books.

28. From another French book of about the same date (the beginning of the 16th century), "The Shepherd's Calendar," of which there were a great number of English editions, even as late as 1656, the cuts being imitated from these blocks.

29. A page from one of the beautiful "Books of Hours," which were mostly printed on vellum, every page of which is decorated more or less with this sort of picture. Here is the calendar, with the signs of the Zodiac, the work of the months, the saints that occur in it, and games and sports; on the other side is the Sangraal. This book is throughout in the same style—wholly Gothic. It was printed in 1498, and about twenty years after these service-books became very much damaged by having Renaissance features introduced from German artists of the time.

30. Another page from the same book. The Resurrection, and the raising of Lazarus are the principal subjects.

31. Nominally an Italian woodcut; the book was printed at Milan, but this cut is probably of German design, if not execution.

32. From a very beautiful book in the Florentine style. One of the peculiarities is the copious use of white out of black.

33. Another from the same—"The Quatre reggio," 1508.

34. Another, very characteristic of the Florentine style, with its beautiful landscape back ground.

35. This is one in which the ornament has really got into the Renaissance style. It is a sort of "Lucky Book," with all sorts of ways of finding your fortune, discovering where your money has gone, who is your enemy, and so on. One of the Peschia books, actually printed at Milan, but of the Venetian school.

36. From a book of the Venetian style, about the same date. I show it as an example of the carefulness and beauty with which the artists of the time combined the border work with the pictures. There is something very satisfactory in the proportion of black and white in the whole page.

Now you have seen my examples, I want once more to impress upon you the fact that these designs, one and all, while they perform their especial function—the office of telling a

tale—never forget their other function of decorating the book of which they form a part; this is the essential difference between them and modern book illustrations, which I suppose make no pretence at decorating the pages of the book, but must be looked upon as black and white pictures which it is convenient to print and bind up along with the printed matter. The question, in fact, which I want to put to you is this, Whether we are to have books which are beautiful as books; books in which type, paper, woodcuts, and the due arrangement of all these are to be considered, and which are so treated as to produce a harmonious whole, something which will give a person with a sense of beauty real pleasure whenever and wherever the book is opened, even before he begins to look closely into the illustrations; or whether the beautiful and inventive illustrations are to be looked on as separate pictures embedded in a piece of utilitarianism, which they cannot decorate because it cannot help them to do so. Take as an example of the latter, Mr. Fred. Walker's illustrations to "Philip" in the "Cornhill Magazine," of the days when some of us were young, since I am inclined to think that they are about the best of such illustrations. Now they are part of Thackeray's story, and I don't want them to be in any way less a part of it, but they are in no respect a part of the tangible printed book, and I do want them to be that. As it is, the mass of utilitarian matter in which they are embedded is absolutely helpless and dead. Why it is not even ugly, at least not vitally ugly.

Now the reverse is the case with the books from which I have taken the examples which you have been seeing. As things to be looked at they are beautiful taken as a whole; they are alive all over, and not merely in a corner here and there. The illustrator has to share the success and the failure, not only of the wood cutter, who has translated his drawing, but also of the printer and the mere ornamentalist, and the result is that you have a book which is a visible work of art.

You may say that you don't care for this result, that you wish to read literature and to look at pictures; and that so long as the modern book gives you these pleasures you ask no more of it; well, I can understand that, but you must pardon me if I say that your interest in books in that case is literary only, and not artistic, and that implies, I think, a partial crippling of the faculties; a misfortune which no one should be proud of.

However, it seems certain that there is growing up a taste for books which are visible works of art, and that especially in this country, where the printers, at their best, do now use letters much superior in form to those in use elsewhere, and where a great deal of work intending to ornament books reasonably is turned out; most of which, however, is deficient in some respect; which, in fact, is seldom satisfactory unless the whole page, picture, ornament, and type is reproduced literally from the handiwork of the artist, as in some of the beautiful works of Mr. Walter Crane.

But this is a thing that can rarely be done, and what we want, it seems to me, is, not that books should sometimes be beautiful, but that they should generally be beautiful; indeed, if they are not, it increases the difficulties of those who would make them sometimes beautiful immensely. At any rate, I claim that illustrated books should always be beautiful, unless, perhaps, where the illustrations are present rather for the purpose of giving information than for that of giving pleasure to the intellect through the eye; but surely, even in this latter case, they should be reasonably and decently good-looking.

Well, how is this beauty to be obtained? It must be by the harmonious co-operation of the craftsmen and artists who produce the book. First, the paper should be good, which is a more important point than might be thought, and one in which there is a most complete contrast between the old and the modern books; for no bad paper was made till about the middle of the 16th century, and the worst that was made even then was far better than what is now considered good. Next, the type must be good, a matter in which there is more room for excellence than those may think who have not studied the forms of letters closely. There are other matters, however, besides the mere form of the type which are of much importance in the producing of a beautiful book, which, however, I cannot go into to-night, as it is a little beside my present subject. Then, the mere ornament must be good, and even very good. I do not know anything more dispiriting than the mere platitudes of printers' ornaments—trade ornaments. It is not uncommon now-a-days to see handsome books quite spoiled by them—books in which plain, unadorned letters would have been far more ornamental.

Then we come to the picture woodcuts. And here I feel I shall find many of you differing

from me strongly; for I am sure that such illustrations as those excellent black and white pictures of Fred. Walker could never make book ornaments. The artist, to produce these satisfactorily, must exercise severe self restraint, and must never lose sight of the page of the book he is ornamenting. That ought to be obvious to you, but I am afraid it will not be. I do not think any artist will ever make a good book illustrator, unless he is keenly alive to the value of a well-drawn line, crisp and clean, suggesting a simple and beautiful *silhouette*. Anything which obscures this, and just to the extent to which it does obscure it, takes away from the fitness of a design as a book ornament. In this art vagueness is quite inadmissible. It is better to be wrong than vague in making designs which are meant to be book ornaments.

Again, as the artists' designs must necessarily be reproduced for this purpose, he should never lose sight of the material he is designing for. Lack of precision is fatal (to take up again what I have just advanced) in an art produced by the point of the graver on a material which offers just the amount of resistance which helps precision. And here I come to a very important part of my subject, to wit, the

Fig. 4.—Italian School. The Descent of Minerva. From the Quatrereggio. Florence, 1508.
[Size of Original.]

relation between the designer and the wood-engraver; and it is clear that if these two artists do not understand one another, the result must be failure; and this understanding can never exist if the wood-engraver has but to cut servilely what the artist draws carelessly. If any real school of wood-engraving is to exist again, the wood-cutter must be an artist translating the designer's drawing. It is quite pitiable to see the patience and ingenuity of such clever workmen, as some modern wood-cutters are, thrown away on the literal reproduction of mere meaningless scrawl. The want of logic in artists who will insist on such work is really appalling. It is the actual touches of the hand that give the speciality, the final finish to a work of art, which carries out in one material what is designed in another; and for the designer to ignore the instrument and material by which the touches are to be done, shows complete want of understanding of the scope of reproducible design.

I cannot help thinking that it would be a good thing for artists who consider designing part of their province (I admit there are very few such artists) to learn the art of wood-engraving, which, up to a certain point, is a far from difficult art; at any rate for those who have the kind of eyes suitable for the work. I do not mean that they should necessarily

always cut their own designs, but that they should be able to cut them. They would thus learn what the real capacities of the art are, and would, I should hope, give the executant artists genuine designs to execute, rather than problems to solve. I do not know if it is necesssary to remind you that the difficulties in cutting a simple design on wood (and I repeat that all designs for book illustrations should be simple) are very much decreased since the 15th century, whereas instead of using the knife on the plank section of the wood, we now use the graver on the end section. Perhaps, indeed, some of you may think this simple wood cutting contemptible, because of its ease; but delicacy and refinement of execution are always necessary in producing a line, and this is not easy, nay it is not possible to those who have not got the due instinct for it; mere mechanical deftness is no substitute for this instinct.

Again, as it is necessary for the designer to have a feeling for the quality of the final execution, to sympathise with the engraver's difficulties, and know why one block looks artistic and another mechanical; so it is necessary for the engraver to have some capacity for design, so that he may know what the designer wants of him, and that he may be able to translate the designer, and give him a genuine and obvious *cut* line in place of his *pencilled* or *penned* line without injuring in any way the due expression of the original design.

Lastly, what I want the artist—the great man who designs for the humble executant—to think of is, not his drawn design, which he should look upon as a thing to be thrown away when it has served its purpose, but the finished and duly printed ornament which is offered to the public. I find that the executants of my humble designs always speak of them as "sketches," however painstaking they may be in execution. This is the recognised trade term, and I quite approve of it as keeping the "great man" in his place, and showing him what his duty is, to wit, to take infinite trouble in getting the finished work turned out of hand. I lay it down as a general principle in all the arts, where one artist's design is carried out by another in a different material, that doing the work twice over is by all means to be avoided as the source of dead mechanical work. The "sketch" should be as slight as possible, *i.e.*, as much as possible should be left to the executant.

A word or two of recapitulation as to the practical side of my subject, and I have done. An illustrated book, where the illustrations are more than mere illustrations of the printed text, should be a harmonious work of art. The type, the spacing of the type, the position of the pages of print on the paper, should be considered from the artistic point of view. The illustrations should not have a mere accidental connection with the other ornament and the type, but an essential and artistic connection. They should be designed as a part of the whole, so that they would seem obviously imperfect without their surroundings. The designs must be suitable to the material and method of reproduction, and not offer to the executant artist a mere thicket of unnatural difficulties, producing no result when finished, save the exhibition of a *tour de force*. The executant, on his side, whether he be the original designer or someone else, must understand that his business is sympathetic translation, and not mechanical reproduction of the original drawing. This means, in other words, the designer of the picture-blocks, the designer of the ornamental blocks, the wood-engraver, and the printer, all of them thoughtful, painstaking artists, and all working in harmonious co-operation for the production of a work of art. This is the only possible way in which you can get beautiful books.

DISCUSSION.

Mr. LEWIS DAY expressed his thorough agreement with Mr. Morris, and the pleasure it had afforded him to hear the paper. There were plenty of competent lecturers who could talk very well on any subject under the sun, but it was a very different thing to hear a man speak straight out from his heart on a subject which he had made thoroughly his own. A comparison had been drawn between the old printing and the new. He did not pretend to be learned with regard to old printing, and could not, therefore, attempt to criticise anything which had been said about it; he was content to enjoy the old work. But really the two things were hardly to be compared; the old books were few, produced by the few, and for the few; whilst the new were for the many, done by the many, and there were a great many too many of them. He sympathised entirely with Mr. Morris when he spoke of book illustration as it should be, but doubted very much if that ever would be. He believed in many impossibilities, but not in that one, and he should really like to know how far Mr. Morris himself believed in it. Mr. Morris had lately been printing books himself, having designed type for the purpose, and very beautiful work he had turned out. But that formed

only, as it were, a little oasis in the wilderness of general printing, and did not go far towards fertilising the dead level of dreary monotonous trade-work all around. One obvious reason why the new work was so different from the old had been referred to by Mr. Morris when he spoke of sketches and designs. Now-a-days, if a man had to make designs for book illustration, he was, first of all, asked to send in rough suggestions; then he had to make what are called "finished" drawings of such as were approved, to be again submitted to the publisher and his head man, and all sorts of people who did not know anything about it. Even when they did not take what good there was in a thing out of it, and produce it vilely, they were pretty sure to insist upon all sorts of preliminary business, by which the heart was taken out of the artist. He should like to know if Mr. Morris really had any hope of general improvement in book illustration; it was only faith that worked miracles, and this would certainly be a miracle. The man who believed in it might accomplish it; and if anybody could do it Mr. Morris could.

Mr. F. S. ELLIS said he also entirely agreed with all that Mr. Morris had said, and he had the greatest hopes of a good result from the efforts Mr. Morris had lately made. Having been only a publisher—though he was one no longer, and not in any sense an artist—he could only look at the matter from his own point of view. He thought publishers would stand very much in their own light if they interfered with an artist, when they had found one capable of illustrating their books in a proper manner. If books were sensibly and properly illustrated, he felt sure the public would be only too thankful to get them, and the whole system would soon undergo a very material improvement.

Mr. MATTHEW WEBB suggested that there was a practical difficulty in producing woodcuts, which should combine the two qualities of illustrating the story and at the same time ornamenting the book. For ornamental purposes there should be very little light and shade, but their absence would materially interfere with the story-telling power.

Mr. HUGH STANNUS said his knowledge of this subject began just where the paper left off. Once or twice in his life he had been able to purchase some of the fine old Italian woodcut books, dating from the beginning to the middle of the 16th century, which was just after the period Mr. Morris had dealt with. He could only hope that he would carry on the subject, which was a most interesting and important one, and give them the result at some future meeting.

Mr. J. SACHS thought wood engravers should be encouraged to develop their birth-right, which was the production of texture. There was hardly any art in black and white which could produce texture like wood engraving; it could be seen in any common catalogue. He must take exception to the remark that wood engraving could be learned easily. He had been an apprentice himself, and had had many apprentices, and he was prepared to say that no one could produce even a sound line without three or four months steady application. It had often been said that Albert Durer and Holbein engraved their own blocks, which was absurd. They evidently employed block cutters to cut the drawings which they had made.

The CHAIRMAN, in moving a vote of thanks to Mr. Morris, said he could not offer any critical obser- vaations on the subject of the paper, but there were one or two points connected with it which specially interested him. When Mr. Morris was considering the date of some of the blocks it struck him that the plants and trees represented would, in some cases, furnish a clue. There was one block, said to be Italian, which Mr. Morris thought must have been cut by a German. He should say most probably, for the plant represented seemed to him to be the mountain ash. In the Florentine engraving of 1508, which followed, the tree was, apparently, a Lombardy poplar, and if so, it was interesting, because the tree was introduced from America, and the block showed that it had already become common in Italy at that date. Turning to woodcuts in modern books, he could not help referring to Walter Crane's "Grimm's Tales," one of the best illustrated books he had seen for a long time. He always purchased ten or twelve copies of all Mr. Crane's cheaper books, and he had distributed that one very widely. He might perhaps be allowed to say, quite incidentally, that he did not share Mr. Morris's prejudice against the unjust judge who took money from both parties to any suit he was trying. In the East he was considered the perfect judge who took a bribe from each litigant, and returned it to the unsuccessful one, who then felt satisfied that the judge had done everything possible for him, but was unable to decide in his favour. In conclusion, he wished the proprietors of illustrated papers would do more for the cause of the good decoration of books. They certainly might lead the way in this branch of the revival of national taste. He had for years been carrying on a correspondence with the managers of some of these papers, in the hope of inducing them to give up advertising on the backs of their best illustrations, and so completely spoiling them. The manager of the *Graphic* wrote to him a year or two ago, to say that his criticisms had been taken seriously to heart, and that when the existing contracts ran out they would try to avoid the pernicious practice; but they had not fulfilled their promise. Probably the receipts from the advertisers were too great a temptation for the proprietors. The practice was more general and obtrusive than ever, and he had in consequence given up binding the weekly illustrated papers, for in book form they were now offensive to the eye. He was on the free list of the

Graphic, and it might seem ungracious to look a gift horse in the mouth; but it was in the interest of the illustrated papers themselves that he raised this protest, for such sordid "double-dealing" has always proved the damnation of art.

The vote of thanks having been carried unanimously,

Mr. MORRIS, in reply, said it was a pity that the contrary view to his own had not been put forward by some one, as there was a good deal to be said *pro* and *con*. What Mr. Sachs had said about texture was very true, but it applied after all to a particular kind of wood-cutting, not to that which he was thinking of as being suitable to the ornamentation of a page. He remembered a lecturer showing a very beautiful slide of Bewick's starling, which looked exceedingly handsome, but it had no relationship whatever to the type of the page on which it appeared, or rather the type had no relationship to it, and the result was that the starling did not make an ornament to the page, and one would prefer to have a separate proof of the starling. That was a strong case, because he yielded to no one in his admiration for Bewick's work, especially when it was employed on fur and feathers. But this view of texture may be carried so far as to apply it to the mere presentation of outline; since it made all the difference in the world whether those lines were cut nice and round, and sweet, or whether they were reduced to a straight needle point on the one hand, or, on the other hand were chopped out and were made edgy and sour. He did not propose to go into any battle of the styles, but the page of the book, the type, and the woodcut ought to go together. If it were necessary to have such woodcuts as Mr. Fred Walker's illustrations to "Philip," the type ought to go with them, to be of the same style. But though this might be possible, it was unnatural, because the essential character of a book was that it was stamped; printers called the types stamps, and the woodcuts were stamps. There ought to be that same kind of clearness and distinctness—that absence of vagueness which you got in the stamping of a coin. Mr. Webb said there might be a difficulty in reconciling the story-telling function of a woodcut with its ornamental function, and no doubt that was true; but it seemed to him that it was just that kind of difficulty or limitation which made an art worth following. If there were no difficulty in carrying out a work of art in any special material, instead of learning to be an artist in pottery, or glass, or wood-cutting, why not follow the most simple and direct form of art, which gave the advantages of all others, not perhaps in the easiest, but in the fullest, way—that of oil painting. But that was not what was wanted. Oil painting might be the most important of all the arts, though he was not quite sure about that; but nevertheless you wanted other arts as well. The woodcutter or the artist had no more right to grumble at the conditions under which he worked than the poet had at having to write in rhyme instead of prose. If he wanted to write prose he could do so. As a matter of fact, if books were largely ornamented in this way, some *modus vivendi* would be found between the ornamental and the story-telling capacity of the art; a school would grow up which would have its own due and proper conventions, under which it would work with perfect ease. The question raised by Mr. Day as to what hope there was for an improvement in book illustration and ornamentation, was really whether it could be hoped for as an ordinary and general thing. He did see certain difficulties, which mostly reduced themselves in the long-run into commercial ones, with which he was not bound to deal on the present occasion. If people chose, they could have such books in very large measure, but no doubt the commercial difficulty would put a stopper on many attempts to decorate books properly. He thoroughly sympathised with what Mr. Day said about the publisher and his man interfering with the artist. The publisher ought to select the artist, tell him what the book was, and the subject required, and let him do his best. But there was one thing in favour of the possibilty of having beautiful books; they were self-contained. If he were asked whether it were possible to have buildings generally good in the present day, he should say, no; but, in the case of books, which were self-contained things, he would say yes. There were not the same difficulties with a book as with many other articles of commerce. The first thing necessary was to have a certain number of artists who had an intense desire to produce work suitable for book ornament; and those artists would, in some way, force the public to give them an opportunity for producing those books. He threw the whole burden really on the group of which he was a humble member, the artists themselves; the public could only take such books as were offered them. The publishers' part was to open their purse as widely as possible, not be afraid to spend a good deal of money on a good book, though they only sold a few copies. Finally, even if books were not beautiful, they migh be made tolerably good looking. Perhaps some little advance had been made. The principal difficulty in getting a cheap book to look well was the paper, but if people would only turn their attention to this matter, they could easily get paper much better for its purpose than what was now considered good paper—paper which would show on the surface of it that it was common paper, but would not be disagreeable to handle or read, and would not be of that horrible shiny character, and look as if you could rub it all to pieces, which, in fact, you could. Some books you could not even carry comfortably from one end of a room to the other, on account of the extra weight of the adulterants necessary for that kind of paper. He had had in his hand a moderate sized book, a royal 8vo., which weighed as heavy as the biggest folio of the 15th century. All that extra weight was not real finish, it was

only trade finish, and was done in order that the books might sell. There was as much hope of doing something in the way of producing good-looking and even beautiful books, as of getting any betterment in any kind of decoration whatever; and after all it need not cost more to print books from beautiful stamps rather than ugly ones. He had the highest possible hopes, if artists would only be true to themselves.

NINTH ORDINARY MEETING.

Wednesday, February 10, 1892; The Right Hon. Sir LYON PLAYFAIR, K.C.B., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Ashburner, Lionel Robert, C.S.I., 9A, Gloucester-place, Portman-square, W.
Hervey, Hubert J. A., 12, Lowndes-street, S.W.
Hughes, John, Chester; and 16, Great George-street, S.W.
Jex, Edward, 27, St. Mary-at-Hill, E.C.; and the Dukeries, Springfield, Chelmsford, Essex.
Rickmann, Adolph, 59, Knightrider-street, E.C.
Sessions, Frederick, Russell-house, Gloucester.
Simpson, Edward Henry, 100, St. Martin's-lane, W.C.
Smith, W. A., Houghton-house, Arundel.

The following candidates were balloted for and duly elected members of the Society:—

Ames, Thomas R. J., 49, Maury-road, Stoke Newington, N.
Browne, Rev. Canon George Forrest, B.D., 54, Bateman-street, Cambridge, and 2, Amen-court, E.C.
Bryden, W. R., 1, George-street, Buxton.
Buchanan, John Young, M.A., F.R.S., 10, Moray-place, Edinburgh.
Chubb, John C., 128, Queen Victoria-street, E.C.
Clarke, Somers, F.S.A., 15, Dean's-yard, Westminster, S.W.
Constable, Archibald, 14, Parliament-street, S.W.
Corder, William, Feeringbury, Westbourne-road, Edgbaston, Birmingham.
FitzGerald, Prof. Maurice Frederick, B.A., Queen's College, Belfast.
Gaymer, John, North Walsham, Norfolk, and John-street Adelphi, W.C.
Gujpatee, Rajah Goday Naraen, Rao, Vizagapatam, India.
Haden, William Nelson, Homefield, Trowbridge.
Halsey, W. S., 213, Cromwell-mansions, S.W.
Hawkins, Herbert Spong, London, Brighton, and South Coast Railway, London-bridge, S.E.
Hughes, John Griffith, Atlantic Engine Works, Bootle.
Kirkaldy, James, 68, East India-road, E.
Ledward, Thomas, 9, Pendrell-road, Brockley, S.E.
Macan, H., M.A., Imperial-buildings, Ludgate-circus, E.C.
Mackenzie, Captain R. J. H. L., R.E., Karachi, India.
Miller, Adam, 11, Queen Victoria-street, E.C.
Oppert, Dr. Gustav, Presidency College, Madras.
Pascoe, James Rogers, Pyrmont, Woodford-green, Essex.
Penfold, Harold, 14, Priory-road, Bedford-park, Chiswick.
Rose, Tom Kirke, 9, Royal Mint, E.
Rowell, Herbert, Hebburn-hall, Hebburn-on-Tyne.
Sibson, Alfred Edward, 2, St. John's-villas, Palmerston-road, Buckhurst-hill, Essex.
Thorp, Walter, B.Sc., The Limes, Henry-road, New Barnet.
Travancore, His Highness Sir Rama Varma, Maharajah of, G.C.S.I., The Palace, Trevandrum, Travancore, India.
Watney, Walter D., 33, Poultry, E.C.
Wilson, Captain Robert Charles Dighton, 21, Chesham-street, Belgrave-square, S.W.
Wilson, Walter H., Queen's-road, Belfast.

The paper read was—

BURNING OILS FOR LIGHTHOUSES AND LIGHTSHIPS.

By E. PRICE EDWARDS.

This paper is not intended to re-open the controversy in respect of the relative merits of oil, gas, and electricity as lighthouse illuminants. My purpose is to give a simple account of the use of various kinds of oil for the illumination of lighthouses and lightships in this and neighbouring countries; to show what has been done in the past and what is being done at the present time.

It should also be understood that I do not propose to enter into minute technical details regarding the chemical composition of the oils, but shall present to you facts of a more or less general but essentially practical character, which have come under my observation while carrying out my duties as an official of the Trinity-house Corporation.

The importance of the subject as affecting the safety of life and property at sea, and facilitating navigation in the dangerous waters near to our shores, will probably be regarded as sufficient justification for its presentment before this Society.

Up to the middle of the last century, and in some cases up to the early part of the present century, British and other sea lights were

simply bonfires fed with wood or coals, or bales of pitch and oakum, burned in open fixed grates, or swinging iron baskets, known as "chauffers." Such lights as guides or warnings to mariners were frequently of the least service when most needed; at the best they were uncertain and insufficient, their smoky, ill-burning flames or red-hot fuel being visible at very short distances at sea. It is said, however, to have been an advantage possessed by these bonfires that their light was, at times, reflected in the sky, whereby mariners were enabled to fix approximately the position of the light-tower itself. The employment of these fiery materials seems to have lessened when candles of tallow came into use. One trustworthy record of this we find in Smeaton's work on the Eddystone Lighthouse, wherein he says that the light was maintained with twenty-four candles, "whereof five made two pounds." He further tells us that it was very necessary to keep the lantern cool, complaint having been made of "it being so hot, especially in the summer, as to give much trouble by the running of the candles." It will be understood that an important function in connection with the use of tallow candles was the snuffing of them, and the old clock in the Eddystone tower was set to strike once every half-hour "to warn the keepers when to snuff the candles."

It is not easy to find any exact records of what was the actual practice in respect of the majority of the lighthouses in those comparatively dark ages, but stated in general terms it may be accepted that wood, pitch bales, coals, and candles, were the main illuminants for lighthouses up to the middle of the last century, and that they were all miserably inefficient for the purpose.

As an illuminating agent for domestic purposes, oils of various kinds have been, as you must all be well aware, employed from time immemorial, and it is more than probable that, for small harbour and fishermen's lights, oil of some kind was used, but the appliances for burning oil were then so imperfect that a light so produced was regarded as quite inferior to a coal fire.

Not until the invention of the Argand oil burner, about 1784, was anything like a real advance made in the use of oil for sea lights. Most of the difficulties which had previously prevented oil from being used for that purpose were overcome by the splendid invention of M. Argand, and thenceforward oil quickly displaced all other illuminating agents for lighthouses. It is now more than 100 years ago since that distinguished Frenchman perfected his burner, and to this day the large majority of oil-burning lamps are constructed on the principle then discovered and realised by him.

Perhaps I may be here permitted to refer briefly to the manner in which oil is consumed and light produced while a lamp is in operation. Of course, the process is quite familiar to many of my hearers; but, as it will be a convenience to me to state it here, and it may possibly be useful information to some of you, I will ask the indulgence of those who know all about it. In the first place, it should be realised that, when oil of any kind is consumed, by burning in a lamp or elsewhere, and flame is the result, the liquid itself is not inflamed. We talk freely enough of the burning of oil, but what really burns is the vapour or gas of the oil. In lighting a lamp, in the first instance, the flame of a taper or match is applied to a portion of the oil-sodden wick, and the heat of this flame converts the oil in that part of the wick into vapour or gas, and the same flame ignites the oil vapour. The burning vapour will then continue the manufacture of more vapour, as additional oil is supplied to the wick, and thus the oil will be consumed by evaporation, until there is no more oil in the lamp to be drawn up the wick for conversion into oil vapour. One other point to be borne in mind is that, in the act of burning, the vapour combines chemically with the oxygen of the atmosphere; and, as oxygen is the principal supporter of combustion, it follows that, the more effectually air containing oxygen can be supplied to the flame, the more perfect and vigorous will be the burning of the vapour.

It was the recognition of this principle which enabled Argand to accomplish his great work, and to produce an oil burner associated with a glass chimney, by means of which the flame of a cylindrical wick was fed with air internally and externally, whereby vastly improved combustion of the oil vapour was effected, the smoky and snuffy solid wicks then used for oil lights were banished and the maintenance of a clear steady flame rendered possible. Briefly stated, the great invention consisted of the introduction of a hollow cylindrical instead of a solid wick, working on a hollow metal cylinder open at the bottom and at the top, whereby air was admitted into the centre of the burning ring at the top to the wick. A glass cylinder outside the wick drew up a circular current of air, and

caused it to impinge upon the outside surface of the flame, and also prevented irregular draughts and puffs of air from striking the flame. With this burner was associated a cistern, so placed that the oil should flow by gravitation down the supply pipe to the burner, and, immersing the wick, would be maintained in the burner tube at a constant level very near to the top of the burner, the portion of wick above this level being fed with oil by capillary action, the oil creeping up the wick to the burning point. Of the further extension of the Argand principle I shall speak presently. I refer now to M. Argand's great invention, because it marks the period of the real advent of oil as an illuminant for lighthouses.

At the period indicated fish oils of several kinds were employed for various purposes, including illumination, but the lighthouse authorities seem, by common consent, to have adopted spermaceti oil, obtained from the South Sea whale, as the most suitable for their purposes, and at the close of the last century this was, in the northern latitudes, in pretty general use. From about 1790, sperm oil was burned with good results in the Argand lamps used for lighthouses in England, Scotland and Ireland, the United States, France, and other European countries up to 1832. In that year France changed her oil, but Great Britain and Ireland held on to the sperm for another twelve years, the authorities being well satisfied with its suitability and efficiency, and being apparently unwilling to make a change which might prove of doubtful advantage. At this time the market price of sperm oil ranged from 5s. to 8s. per gallon, and there was no lack of the commodity. But as time went on, prices showed a continued upward tendency; ominous rumours were current that the supply being dependent upon the success of the whaling industry would become restricted as the demand increased. Furthermore, colza or rape-seed oil was entering into competition with it at about half the price, and in 1845, after careful experiments, the Trinity-house Corporation acted upon the recommendation of a Select Committee of the House of Parliament, and determined to adopt this oil for their lighthouses and lightships in lieu of sperm, on account chiefly of the much lower price of the former.

This is the oil which had been used in French lighthouses since 1832, with good effect. The oil is obtained by expression from the seeds of the rape plant, a small wild cabbage (*Brassica oleracea*) grown to a considerable extent in France and Belgium. Its price per gallon was then 3s. 6d. as against 7s. for sperm, and therefore its adoption effected a large saving. When its employment was under consideration, some trials as to its value as a lighthouse illuminant showed that the lamps then in use with sperm were not suited for burning this vegetable oil; but, by the efforts of Mr. Wilkins, of London, Mr. George Herbert, of the Trinity-house, and Mr. Stevenson, in Scotland, who each designed a lamp suitable for burning rape-seed oil, this difficulty was overcame. It was also found that with suitable burners the light-yielding powers of the fish and vegetable oils were about equal, while there was no material difference as regards consumption. Thenceforward all classes of burners used in lighthouses and on board lightships in the United Kingdom were gradually adapted for the use of the new oil. Its great safety, its effective illuminating power, and its economy, as compared with sperm oil, combined to cause it to be regarded as a most desirable illuminant; and, for many years it has been in use, latterly, however, in diminishing quantities. In connection with the contracts made for the supply of this oil for lighthouse purposes, the greatest care has always been exercised to ensure the oil so supplied being of the purest and best quality. The samples submitted with the annual tenders, and the deliveries subsequently made by the contractor, were subjected to severe tests, comprising chemical examination for free acids or adulterating elements, test of capacity to withstand congelation at 25° F., 16 hours' continuous burning, during which period the wick must not be trimmed, and measurements of the illuminating power taken every few hours, and, at the end, the wick carefully examined, to see if any incrustation had formed which would injuriously affect the maintenance of the light. Each cask of oil delivered is sampled, and carefully tested, as above indicated, to ensure its being of a quality equal to that submitted with the tender of the firm holding the contract. Any impurity in colza oil is tolerably certain to make itself evident in the burning: the foreign substance will most probably carbonise in the wick at the burning point, and will hinder the proper quantity of oil being evaporated, thus impairing the effectiveness of the flame, and, if prolonged, causing it to sink, so as to be of no value as a light. It is obvious that the strictest tests are a necessity. The oil

for the Trinity-house service, when approved, is started into large iron cisterns, each capable of holding 9,000 gallons, and after being allowed to settle down for a month or two, a process which improves all animal and vegetable oils, is drawn off into iron drums (five gallons each) tinned inside, and despatched by the lighthouse tender to the lighthouse or lightships.

In 1852, a new Lighthouse Board, for the United States of America was constituted, and one of the first questions they dealt with was that relating to the substitution of another and cheaper oil in place of the sperm oil there in use. Following the lead of France and England they inquired as to the possibility of employing rape-seed oil. The difficulty experienced in their investigation was that this oil would have to be imported from Europe, as no available means existed for its home production. An endeavour was made by the Board to stimulate the cultivation of the rape plant and the manufacture of the oil in America, but without success. While this effort was in progress, Professor Henry made a number of experiments with various oils, but more particularly with lard oil, and arrived at the conclusion that it was possible to burn this oil satisfactorily in lighthouse lamps. Moreover it could with facility be manufactured in America, and supplied at a price considerably less than would have had to be paid for colza. Consequently, about 1861 lard oil became the illuminant in all the lighthouses of the United States, a special lamp for burning it having been designed by Mr. Joseph Funck, the foreman of the lamp shop of the United States Lighthouse Board. The principle of the lamp was that of the Argand, but its speciality was that the reservoir for the oil was so placed that the heat of the flame passed through its centre, it being a necessity in order to get the best effects from this oil that it be kept at a high temperature, it having a marked tendency to congeal at temperatures below the normal.

The possibility of using petroleum had been many times mooted in the United States, but no safe methods of burning it at this date seem to have been available. Sundry accidents had happened in its manipulation, and petroleum had gained the reputation of being a dangerous explosive liquid which should only be handled with the greatest amount of caution. It was not, therefore, thought desirable to depart from using the safe lard oil. As late as 1872 a Committee from the Trinity-house of London visited America, and found lard oil in general use in the lighthouses of the country, and it continued to be so employed up to 1879. The average price paid for it was 1 dollar 10 cents per gallon, as against 1 dollar 64 cents for sperm.

Among other vegetable oils which have been used for lighthouses may be mentioned olive and cocoa-nut oils. The former has yielded very satisfactory results in a burning test made at the Trinity-house about six years ago; the illuminating power obtained being quite equal to that obtained from the best colza. The oil, however, was quite solid at 25° Fahr. It was, in former days, used in some Irish lighthouses, and many of the Mediterranean lights were also illuminated by its agency; but its cost, in 1867, was about 6s. per gallon, as against 3s. for colza; therefore it could have no chance in the competition with colza, apart from its liability to congeal. It is still used in some of the small Mediterranean and Asiatic lights.

Cocoa-nut oil has been, and still is, employed to a considerable extent for lighthouses in India and Ceylon, but it is now being displaced by mineral oils. A sample tried at Trinity-house showed that, when kept in a liquid state, it could be burned, and yielded fairly satisfactory illuminating results; but it was necessary to keep a lamp burning under the oil cistern to keep it fluid. It is not at all adapted for illuminating purposes in these latitudes, as it becomes solid at ordinary temperatures. Moreover, its price here would not have allowed it to compete with colza.

The progress made in the further development of lighthouse burners during the period when sperm and colza were the illuminants is worthy of notice, as the additional knowledge gained had doubtless a great deal to do with the further utilisation of oil for lighthouses. The Argand principle had to be adapted to new conditions when the lens system of Fresnel came into use. Previously the great beacon lights on our coasts had been produced by a number of single-wicked Argand burners, each placed in a reflector. If the light was meant to be fixed, *i.e.*, continuously shining, showing with equal effect all over the arc to be illuminated, the lamps and reflectors would be suitably arranged around a cylindrical framework, so that their rays should proceed continuously in the direction required; but if the light were to be revolving or flashing, a certain number of the lamps and reflectors would be fixed on each face of a polygonal framework,

and the whole framework set in rotation, whereby each group of lamps on a face would send out a beam of their combined rays, and each beam would successively travel over the seaward arc requiring to be illuminated. This is, as you doubtless are aware, known as the catoptric system of illumination. It is in operation at only a very few lighthouses now, and these will probably be changed to the more perfect or lens system in due course. On board lightships, however, the Argand lamps and reflectors have to be retained in consequence of the movements of the vessel rendering lenticular adjustment very difficult and costly. With the dioptric system one large burner only is used, placed in the centre of the lighthouse lantern and surrounded by a structure of glass lenses and prisms, the use of which is no doubt familiar to all. When Fresnel was completing the application of his lens system, the necessity arose of providing a larger and more powerful burner than the single-wicked Argand, and, in conjunction with his friend, M. Arago, he produced an enlargement of the Argand burner, having four concentric wicks. With all the four wicks alight the flame, of this burner was about 4 in. high and about 3½ in diameter. Each wick was independent of the others, air spaces separating the circular wick cases, and the oil was supplied to the wicks by hydrostatic or mechanical pressure. In such burners both sperm and colza oils were freely used, and up to the year 1872 no greater number of wicks than four were employed in any burner, and colza oil was in general use in all British lighthouses.

Sir Lyon Playfair, who has shown his appreciation of the importance of my subject and honoured me, by presiding this evening, will well remember calling the attention of Mr. James Young, in the year 1848, to the oozing out of some petroleum above a coal-working at Alfreton in Derbyshire, and suggesting to him that it might possibly afford a profitable subject for investigation. From that suggestion most important and valuable results have emanated. That particular supply of petroleum quickly gave out, but not until Mr. Young had, after careful observation, formed a theory as to how it had been formed. This theory he subjected to experiment; he followed what he believed to be the natural process by which the petroleum had been formed, and by the slow distillation of coal he produced a liquid (now known as crude oil) somewhat similar to that which had oozed out at Alfreton. The yield of liquid from a ton of coal was about fifty or sixty gallons; but subsequently Dr. Young's attention was drawn to the Torbanehill or Boghead bituminous mineral, which was found to contain a much larger percentage of carbon than the coals he had previously distilled. Subjecting this new raw material to his process, he succeeded in extracting from it as much as 120 gallons of crude oil per ton. There being extensive fields of bituminous shale in Scotland, the extraction of paraffin oil rapidly grew into an important industry.

Briefly stated, the process is to place the shale in retorts to which a gradually increasing heat is applied. All the volatile constituents of the shale are thus vaporised, and the vapours so formed conducted off by pipes to be condensed. The whole of the resultant condensed liquid is crude oil, a dark-green viscous fluid with a specific gravity of ·870 to ·885. A considerable quantity of the vapour remains uncondensed, and is led off to be utilised for heating purposes. The next process is the distillation of the crude oil in order to obtain from it the various products required. This is also a gradual operation, and is continued until the oil is distilled to dryness. The first application of heat to the still releases the most volatile elements; as the heat is increased, the heavier portions of the crude oil are vaporised. It is important to note this operation, showing the quality of the different paraffin burning oils as extracted, The early distillate is given up to the production of gasoline and naphtha, and is cut off when the condensed vapour in a liquid state has a specific gravity of ·770. These products are highly inflammable, that is to say, they will vaporise at comparatively low temperatures. The next section of the distillate is devoted to burning oils, the specific gravity of which ranges from ·770 to ·850. It is this section with which we are chiefly concerned. The further extension of the distillation yields lubricating oils containing solid paraffin. The burning oil is subjected to chemical treatment for purifying, and a process of fractional distillation to enable the oils to be separated into different qualities to suit the markets. For the general public the lighter oils are appropriated, having a specific gravity ranging from ·795 to ·810, and none of these can be vaporised at temperatures below 90° F. (Abel test). The oil for lighthouses is specially selected, and has a specific gravity of from ·810 to ·820 and cannot be vaporised

until subjected to a heat of 145° F. Let me here observe that the temperature at which mineral oil can be vaporised is the test of the safety of any such oil, and is known as its flashing point. The vapour evolved is inflammable in the open, and explosive if confined. I do not mean that any spontaneous inflaming or explosion will take place, but simply that the application of flame to the vapour will ignite it. Specific gravity in itself is not a test to be depended upon. The lighthouse oil, it may be observed, does not give out dangerous vapour until it is heated to a temperature above 145° F.

As I before remarked, the industry of making paraffin-burning oils is a large one in Scotland, the whole having grown out of the enterprise and skill of Mr. James Young, encouraged and assisted by such eminent scientists as our chairman of this evening.

While Dr. Young was pursuing his investigation with the Boghead mineral, the French lighthouse authorities were making trial of oil extracted by distillation from the bituminous schists of the Department of Allier, and found it possible to burn the oil in a single-wicked lamp invented by a M. Maris. The result of the trials was that a few small harbour lights were illuminated with this oil. Some accidents occurred which had the effect of alarming the authorities, and of causing its use to be proceeded with very cautiously, and it was for several years confined to single-wicked lamps.

In 1868 Captain Doty, who had given some attention to the subject of mineral oil burning, came upon the scene, and put himself in communication with various lighthouse authorities. On his introduction by the late Emperor, Napoleon III., to the French authority, he submitted burners with three and four concentric wicks, which he alleged were suitable for burning the new mineral oil, and in 1869 at the La Canche lighthouses a trial of the Doty lamp with schist oil, as then supplied, was made in comparison with a Colza lamp. But although good results as regards the mineral oil burner followed this trial, the further application of this illuminant for lighthouse purposes was not proceeded with owing to the fear of accident by explosion with the schist oils then in the market, the uneasiness being increased by a report made at the time by the chairman of the United States Lighthouse Board, that although mineral oil was abundant in their country, it was not thought advisable to use it in lighthouses there on account of its inflammability. It is possible that the schist oil was either inherently of inferior quality to the Scotch paraffin or was badly made. But however that may be, Young's Paraffin Light and Mineral Oil Company, which was at that time in existence, submitted to the French authorities the paraffin oil manufactured by them, and as a result of the trial made it was found that the Scotch oil was less inflammable and dangerous, and a better illuminant than the schist oil then in use in single-wicked lamps. They further made a careful examination of the relative merits of this oil as compared with all the mineral oils of French origin, with the result that the superiority of the Scotch paraffin was conclusively proved, and in January, 1870, a three years' contract was made with Young's company to supply the oil required. In 1873 we find that the Commission des Phares gave the order for the substitution of mineral oil for colza in all the French lighthouses, on the grounds that its cost was one-half that of colza; that with proper tests on receipt of the oil its safety could be ensured; that the light yielded by it was superior to that from colza, and the lamps with mineral were more easily managed than those burning colza. The burners used were those of Doty and Lepaute, the former gentleman receiving, in recognition of his efforts, a grant from the French Government, in addition to the price of any burners supplied by him.

In this country, the question of using mineral oil in lighthouses had been under consideration before 1868; indeed, both the English and Scotch lighthouse authorities had for some time been inquiring and working at the subject. It is right to say that the intervention of Captain Doty in the investigation and competition helped the matter forward considerably. At first, he submitted to the Trinity Board only a single-wicked Argand burner, adapted for burning mineral oil; but suggestions were made to him at the time as to the mode in which four consecutive wicks were used in some lighthouse oil burners. Upon this hint Captain Doty appears to have acted promptly, for he shortly afterwards produced three and four-wick burners adapted to burn mineral oil, which burners he subsequently, as we have seen, introduced to the French authorities with some success. The Trinity-house engineer, and the engineer to the Commissioners of Northern Lights were at the time experimenting, with the object of adapting the then existing lighthouse burners for the combustion of mineral oil. The Trinity-house proceeded

with the investigations and trials, and ultimately the Douglass mineral oil burner was perfected. The Northern Commissioners accepted Captain Doty's burner as furnishing a solution to their inquiry. The deliberate proceedings taken in connection with the introduction of paraffin as a lighthouse illuminant, are justified by the important considerations which must be taken into account, before a safe and well-tried oil could be displaced in favour of an oil having, to say the least of it, a doubtful reputation.

Elaborate and careful trials were conducted by Dr. Stevenson Macadam, in Scotland, and Professor Tyndall and Mr. Valentin, in England, ably assisted by the engineers to the respective Lighthouse Boards; and, in 1870, Dr. Macadam reported that "paraffin oil consumed in Doty's lamps, alike from readiness in trimming and lighting up, from steadiness of flame, and from high photogenic power, possesses decided advantages over colza oil for lighthouse illumination; whilst the quality of the best mineral oil now to be obtained in the market renders the employment of paraffin oil practically safe." In 1871, Dr. Tyndall supported Mr. Valentin in a strong recommendation that the use of paraffin oil be extended, stating that "the consensus of evidence leaves no doubt upon the mind that, as regards cost and illuminating power, the paraffin light really possesses the advantages claimed for it;" while, from the practical point of view, Messrs. Stevenson and Mr. Douglass reported most favourably upon the new illuminant, and upon the safety and effectiveness with which it could be used in lighthouses. By the year 1873 all doubt had disappeared, and paraffin was rapidly displacing colza oil in the majority of lighthouses in the United Kingdom.

While European authorities were adopting paraffin as a lighthouse illuminant, the United States authorities again resolved to give consideration to the matter. They had become better acquainted with and possibly less timorous of the petroleum which was spouting up so freely in their country. The action of Mr. James Young, and the development of the paraffin industry, opened their eyes to the possibilities of utilising the rock oil of their country. It is a curious fact that before the Americans knew the value of their petroleum, the process of distilling shale and making paraffin, under Young's Patent, was carried on in America. When they realised what their great possessions were, there was, you may depend upon it, a "boom in oil."

In 1874, the Lighthouse Board investigated and experimented: they tried a great number of mineral oils, and in the end resolved to have petroleum of a certain quality. It took several years to change their burners, but ultimately, I believe in 1879, all were adapted, and lard oil became a thing of the past so far as lighthouse illumination is concerned.

In Canada the petroleum obtained in the Dominion had been in use for lighthouse lamps before 1870. In those days Canada was less advanced than she now is, and her coast lights were of a somewhat primitive character, although probably sufficiently effective for the purposes required. The lighthouses were simple structures, built of wood from the forest close by; the burners of simple construction in reflectors; the oil from the nearest source. Under the energetic direction of Mr. William Smith, the Deputy Minister of Marine, many of the lights were subsequently improved by the adoption of the large four-wicked concentric burners, but it was then found that the Canadian petroleum was not suitable for these large burners, as under the great heat developed the wicks were carbonised and capillary action checked. Now, I am informed, the oil for these burners is supplied from New York.

The use of mineral oil for lighthouses has not extended very rapidly in other British colonies. To this day colza is largely employed; but as prejudices against the use of mineral oils die out, and the freight for such oils (unreasonably kept up as regards lighthouse oils on the ground of danger) is lowered, and also as the petroleum found in various parts of the world is brought into practical account, we may expect mineral oil to displace all others.

For those to whom the terms paraffin and petroleum are confusing, let me say that paraffin oil is extracted from bituminous shale, as I have before described, while petroleum exists in the earth as a crude oil, and is drawn therefrom in a liquid state. Speaking generally, it may be said that the crude oil resulting from the destructive distillation of shale is somewhat similar in character to the crude petroleum oil. There are, of course, many differences in detail among all mineral oils, but taking them as crude oils from which burning oils have to be obtained, we may consider the question of how a safe oil for lighthouse purposes can be and is produced. These crude oils are subjected to somewhat similar processes for their refinement. It has been stated that the section of the distillate

devoted to burning oils consists of a mixture of hydrocarbons of varying volatility; the early portion of the distillate is therefore more volatile than the last portion, the former having required less heat to vaporise it than the latter. Suppose then the section of burning oils has been obtained by the application of heat from 300° F. to 600° F., this section may be cut up into further divisions, the first part of which would consist of light oils, with a specific gravity of from ·790° to ·810 and a flashing point, as regards paraffin, of from 90° F. to 105° F., and as regards ordinary petroleum, from 73° to 90° F. Such light oils as these are mostly used by the general public for ordinary burning purposes, and are retailed in this and other countries.

In refining crude petroleum a very large fraction of the burning oil section consists of this light oil, and the refiners are naturally desirous of disposing profitably of this oil, which might, if not available for illuminating purposes, remain on their hands as more or less a waste product. The trade in American petroleum is now a large and important one, but was young and undeveloped when the Petroleum Acts of 1862, 1868, 1871, and 1879 were passed, and the framers of those Acts may have thought it desirable to so far encourage this trade by lessening to a minimum the restrictions upon those light oils being brought into and freely distributed throughout the country. In these Acts the oil indicated as dangerous, and as requiring to be specially restricted as regards its transport and storage in this country, is that which gives off inflammable vapour at a temperature below 73° F. (Abel test), while all oils flashing at or above that temperature are not regarded as dangerous by Act of Parliament. The consequence is, this country is practically flooded with American oil, of which a very large proportion gives off inflammable vapours at temperatures between 73° and 80° F., which oils, in my humble judgment, are essentially dangerous, no matter in what improved or safety lamps they may be used. Temperatures of 73° to 80° F. are frequently experienced in summer weather, and then these oils evolve their vapour. Again, in a lamp burning with this light oil, the conduction of heat from the burning point to the oil receptacle may quite possibly raise the metal, or other material enclosing the oil, to a temperature above 73°; and this heat, communicated to the oil, would cause it to vaporise, and the space above the surface of the oil, if ignited there, would cause an explosion, and if the lamp were upset, the oil would most probably immediately inflame, on coming into contact with the burning wick. From the point of view of danger, I venture to think too much reliance is placed upon special safety lamps, and too little consideration is given to the inherently dangerous nature of the oil used. I fear many, if not the majority, of the accidents which have happened with mineral oil lamps have been due to the fact that large quantities of low-flashing oil are sent unrestricted into the markets of this country, and distributed for sale to all the retail shops in the United Kingdom. Oils of the character here referred to would never be used in lighthouse or lightships, on account of the serious risk which would be incurred of accidental conflagration.

In the majority of cases of refining petroleum no such section as above referred to is cut off, the whole of the fractions of burning oils, from light to heavy, being mixed together. But, in the case of paraffin manufacture, after the light oils are cut off, then what is known as lighthouse oil—of specific gravity ·810 to ·820 and minimum flashing point 145° F.—is cut off. This is the kind of mineral oil which has been in use by the British lighthouse authorities for the past 18 years; and the several firms who annually tender for the supply of this oil are fully aware of the requirements. It does not appear to have been considered by the American petroleum firms worth their while to compete with the Scotch companies for this special business, although tenders are invariably invited by public advertisement. It does not seem that there should be any very great difficulty in supplying American petroleum to meet the requirements of the lighthouse Boards, but they probably are not disposed to cut out of their distillates the limited fractions of the burning oils section which would be necessary. Probably the same reasons apply in some measure to the refiners of Russian oil. Several samples have been sent for testing, but the flashing point in each case was below the specified limit, and in the test lamps at the Trinity-house the flame was inclined to be a little smoky and fell off after seven hours' burning. But it may be hoped that the Baku managers will send another sample taken from a narrower cut out of the best portion of their burning oil distillate.

The paraffin referred to is quite safe to use in lighthouses, and with burners of six and eight wicks. In these large burners the oil in the wick cases is maintained by regulated pressure

at a constant level about three inches below the burner tips, where it is found that the heat of 120° F. is not reached. Just above the position where it is necessary to maintain the constant level, the wick-cases are drilled with small holes, so as to enable the oil to overflow if it should rise above the proper level. As a matter of fact, the pressure causes the oil to have a constant tendency to rise, thus a constant overflow is established, whereby cool oil is continually supplied to the wicks, and prevents the metal at that point from becoming unduly heated. I took the temperature of the overflow oil of a ten-wick burner last week, and found it was 108° F. The lamp was being worked with only a little oil, and the overflow oil was flowing back to the reservoir, the temperature of oil in the reservoir being 94° F. At neither of these temperatures could inflammable vapour be given off, and therefore the oil was as safe as it could be. Oil is quite safe until it begins to evolve vapour. Prevent vapour forming in your lamp, except at the burning point, and you have nothing to fear. This you can achieve by using oil which will not vaporise until it reaches a temperature of say, 120° F. During the eighteen years paraffin has been in use in English lighthouses only one serious accident has happened, and that was due to mismanagement on the part of a keeper.

For lighthouses on isolated rocks at sea, and on board lightships, even the paraffin with flashing point of 145° has not been regarded as suitable. The consequences of an accidental firing of the oil in a rock lighthouse might be very disastrous, and the Trinity-house Corporation with their engineer have not been willing to encourage the possibility of this risk. On board a lightship, where there is a number of swinging lamps in the lantern at the masthead, which in bad weather, as the vessel rolls and labours in the sea, are subject to violent oscillations and jerks whereby the oil is frequently spilled, and in very severe weather sometimes thrown about the lantern, it has not been considered desirable to use the Scotch paraffin; although in French lightships an oil of that character has been burned for some years.

But in the year 1885 an oil was brought to the notice of the Trinity-house, with a flashing point of 250° F. (Abel test). This was an American petroleum, and probably consisted of a portion cut out of the burning oil section rather late in the process of distillation of the crude oil. The promise of this oil was so favourable that careful trials were made with it, and excellent results as regards illuminating power were obtained from it. Its capillarity was a little less than the paraffin in use, and to burn it in the large burners necessitated a raising of the constant level, and a little different adjustment in the burners. Sir James Douglass quickly recognised the value of this oil, and after a practical trial had been made of it in the lamps on board the Goodwin Light Vessel, it was resolved to proceed further. Colza was still the illuminant at rock lighthouses and on board lightships; this new oil could be supplied at about one-fourth the price paid for colza, could be burned more easily in the adjusted lamps, was liked by the lamp-trimmers as being cleaner and more easily managed, and could not become dangerous until heated to 250° Fahr. With all these recommendations, it is not surprising that the Trinity-house, with the concurrence of the Board of Trade, arranged that this oil should be used at all lighthouse and lightship stations where colza was then in use.

On further inquiry, it was found that if there were a demand for such oil, there would soon be a supply to meet it. The Thompson and Bedford Company, of New York, were the first to put the oil into the market, but other companies have proved since that no firm has a monopoly of the supply of this oil. The Broxburn Oil Company sell paraffin oil of similar character, and other Scotch companies are prepared to supply it if required. The Trinity-house at once proceeded to adapt all the remaining colza burners for burning this new oil, and have progressed so much that, instead of taking a contract for 300 tons of colza, as used to be the case, the quantity to be taken this year will probably not exceed 10,000 gallons, if any is taken at all. Such mineral oil as this is, indeed, safe, and ought to commend itself to the public at large. It has been stated that oil of this character develops more heat in burning than the low test oil. If this were really the case, there would still be such a large margin of safety in the oil that it could not be of material consequence. But, from trials made by myself and others, it does not appear that there is a greater development of heat with the high-test oil as compared with low flashing oils.

I made a trial, a few days ago, of five mineral oils burning in domestic lamps of similar construction, and took the temperature of the oil in the reservoir of each after five hours' burn-

ing, the bulb of the thermometer being kept in the oil the whole period. The results are shown in this Table :—

Oil used.	Flashing point. (Abel Test.)	Temperature of oil after 5 hrs. burning.
	Deg.	Deg.
1. High-Test Petroleum ..	248	86
2. Paraffin Lighthouse	154	86
3. Water-white Petroleum..	114	87
4. Russian Petroleum......	86	85
5. Standard-white Petroleum	76	88

I then applied a flame to the filling hole of each successively, and from the first three there was no indication of vapour, although the flame was put completely into the reservoir. On applying the flame to the fourth, there was a slight indication of disturbance; but on applying it to the fifth, an explosion immediately took place, a tongue of flame shooting up from the filling hole about a foot long, and the flame of the burner was forced up the chimney by the pressure of the exploding gas in the oil in the reservoir. This proves that, with No. 5 oil, having a flashing point of 76° F., the oil in the reservoir was heated to 88°, and a large quantity of inflammable vapour had formed, which was stored in the reservoir, and which inflamed violently on applying a lighted taper.

This is a result which deserves the careful consideration of all users of mineral oils. Suppose, while this storage of oil vapour exists in the lamp, the oil in the reservoir requires replenishing. The filling hole will perhaps be opened, and the inflammable vapour liberated; it might then ascend to the flame through the air-holes, or a lighted taper or match brought near, to show much oil to be poured in; in either case the consequences might be very serious.

Other experiments, carried out in greater detail, have been made in this direction, from which similar results were obtained. The three oils which give off no vapour show that safe mineral illuminants are obtainable either of petroleum or paraffin, and that the lighthouse authorities are enabled to use it without risk and without difficulty. The introduction of this oil has enabled Sir James Douglass to perfect his burners of all classes; and the Trinity Board have arranged that the modified burners which have been displacing the colza lamps ashore and afloat, shall be in every case more powerful; and the result is that, while the lights shown for the mariner's benefit have been vastly improved, the cost of producing these lights has been considerably decreased as compared with the colza lights; while the element of safety has been preserved by the adoption of oils which may be consumed in the largest burners without risk.

It may be interesting to note that by the change to mineral oil the illuminants for sea lights have successively been obtained from animal, vegetable, and mineral sources, and that the cost per gallon has descended in the three stages from about 6s. to 3s., and to 1s. 4d. At the present time paraffin of the quality required and high test petroleum can be obtained at about 6d. per gallon. With this great decrease in cost, the question of the relative consumption of colza and mineral oil is practically unimportant, but, as a matter of fact, it is found that in similar burners there is rather less mineral oil consumed to maintain a maximum flame than with colza. The increased power of lights necessarily involves an increased consumption of oil; but the cheapness of the oil makes the additional expenditure a matter of small account.

It may be freely admitted that those who have striven with so much zeal and success to make gas lighting available for lighthouses, have by their efforts greatly stimulated the development of oil burners; and this development has been favoured, in a marked degree, by the introduction of the safe mineral oils to which I have referred. It was thought a great advance when the four-wicked burner was enlarged by two additional concentric wicks; but, since that was accomplished, burners of 8 and 10 wicks have been perfected by Sir James Douglass.

Eight-wick burners, consuming paraffin or high-test petroleum, are now installed at the lighthouses of Coquet, Whitby, and Bishop Rock, Scilly; and ten-wick burners are established at the lighthouses on the Casquets in the Channel Islands, and Round Island, Scilly.

In clear weather, seven of the inner wicks of the 10-ring burner and five of the 8-ring burner are suppressed, the full power of each being employed only when the atmosphere is thickened by fog, mist, or snow. The candle-powers of the unassisted flames of each burner with mineral oil are as follows :—

Trinity-house	Douglass	single-wicked	burner		20	candles
,,	,,	two	,,	,,	60	,,
,,	,,	three	,,	,,	180	,,
,,	,,	four	,,	,,	350	,,
,,	,,	six	,,	,,	835	,,
,,	,,	eight	,,	,,	1,500	,,
,,	,,	ten	,,	,,	2,215	,,

The old four-wicked Fresnel burner, with colza oil, gave 230 candles.

In connection with the oil burners, I must not omit to refer to the very important question of the cotton wicks employed as a vehicle for carrying the oil up to the burning point. With sperm and colza oils a rather hard closely woven wick was in use, and as nearly the whole of the wick was steeped in oil, only about 3-8ths of an inch being above the constant level, its texture and suitability for promoting capillary action were not of great consequence. But when paraffin was introduced, the nature of the oil rendered it necessary to alter the mode of burning. Being so much more volatile than the animal and vegetable oils, it would have been dangerons to bring the constant level of the paraffin very near to the flame, and the oil would not have been consumed satisfactorily. It was, however, fortunately discovered that this oil had great capillarity or creeping power (a peculiarity which is sufficient to explain what has often been called the sweating of metal and glass receptacles of this oil), and that if the wick were immersed up to a point two or three inches below the top the oil would rise in it by capillary action up to the burning point. To facilitate this action it was necessary to displace the old closely woven wick for one of looser texture and of a spongy character. In the investigation of this particular branch of the subject, Sir James Douglass informs me that a great deal of the success attained is due to Mr. Henry Defries, who expended a large amount of time and made many experiments in his efforts to produce a satisfactory wick. His perseverance and intelligent perception of the requirements were ultimately rewarded, and a wick was produced in every way suitable for mineral oil consumption. The theory of using a wick is that it should not be burned; it should act merely as a vehicle for bringing up oil to be converted into vapour, and this vapour only should be burned. That is the theory, but the practice falls short of it. Most wicks get burned and carbonised more or less. And what is the consequence? With carbonised wicks the tendency is for the gas-making action to be arrested, because the charred and cindered part of the wick offers a decided obstruction to the upward passage of the oil to the flame. If the oil cannot get past this obstruction, the flame cannot be maintained, it gradually diminishes, and before long goes out. Moreover, the burning of the wick itself communicates heat to the metal of the wick case, and with a volatile oil this would introduce a rather serious element of danger.

In this connection I may, perhaps, conveniently call your attention to what appears to be an important departure taken by the Broxburn Oil Company. Out of the burning oils section of their distillate from crude paraffin they cut a narrow fraction of oil of a very homogeneous character, with a very limited range of boiling points, but flashing at 100° F. This oil, it is found, lends itself to more perfect combustion than any mineral oil yet known. The processes of creeping up the wick, of forming and burning the oil vapour, are so perfectly effected that the wick itself is not carbonised, and only requires renewing at very long intervals. The lamp you see burning here was lighted on Thursday last, at 12 o'clock, and has not been put out since that time. Every morning the oil cistern has been replenished, but neither the wick nor the light are materially affected.

On the 30th of June last, an Argand burner with this oil, was lighted at 8 a.m., and burned day and night continuously until the 22nd July, when it was put out for want of oil. It burned 532 hours continuously, and at the end the wick, which is now on the table, was clean with very little char upon it.

In certain conditions this may be a very valuable kind of oil for lighthouses, but its flashing point is low for such service. For domestic lamps it may possibly be applied very usefully, for many would consider it a great advantage to keep one wick in a lamp for weeks together without trimming or renewing it. Here is a domestic lamp which Mr. Love, the manager of the Broxburn Oil Company, to whom I am indebted for much useful information, has had under trial for three weeks; the wick has not been changed, the lamp has been lighted every morning and burned for about seven hours, the reservoir being filled daily. Sir James Douglass is sanguine that he can successfully use this oil for illuminating a new lighthouse shortly to be placed at the entrance of the River Usk in Monmouthshire. This light will not be under the constant attendance of a keeper, and the supply of oil to the burner will be automatic, a reducing valve being introduced between the oil reservoir and the burner to render the flow uniform.

A further project Sir James has in view is to use this oil for the illumination of buoys at sea, instead of storing in them compressed gas as now. This project is, however, at present only in the region of experiment.

This leads me to mention another kind of mineral oil light, which has proved very serviceable on the Swedish and Norwegian coasts, which has also been adopted for lighting the Danube entrances, and in several instances in Scotland, at Stoneness in the River Thames. This light burns automatically without a wick at all, and is alight all day as well as all night. The light is produced by the combustion of very volatile petroleum spirit, which gives off vapour at all temperatures. The burner is fed automatically from a reservoir containing a sufficient quantity of spirit to last until it is replenished—perhaps once a fortnight. This light is visited occasionally, only to see that there is a sufficient stock of spirit in the reservoir, and that the automatic action is perfect.

Soft paraffin wax has also recently been submitted for trial as to its suitability for lighthouse purposes. It is now being used in what are known as the Cera lamps on board ships, and, to a limited extent, for domestic purposes. It has many advantages. When carefully freed from oil it requires less air for its combustion than other oils, and is therefore less liable to smoke under unfavourable conditions of burning. It gives more light than colza and other oils, is absolutely safe at a flashing point of 340° F. But it requires special arrangements to keep it fluid, and trouble in melting it in the first instance. For lighthouses purposes, it is not obvious that it can compete with the mineral oils, as now used, especially as regards price and facility of employing it; but the lighthouse authorities will no doubt await further developments of the application of this material with interest.

From time to time oils of various character have been submitted for trial, with a view to their being used for lighthouse purposes; but the paraffin and high-test petroleum have not been excelled, as regards efficiency and suitability, while, in respect of economy, they cannot be beaten. It will, doubtless, be observed that the Russian oils do not appear to have been brought seriously into competition with the paraffin and high-test American petroleum. Possibly it has not been considered worth while to cut out of the burning oils produced the comparatively small quantity of special oil adapted for lighthouse and lightship requirements; but there can be no doubt that the Trinity-house Corporation, and other lighthouse authorities, will gladly welcome any further competitor to supply their requirements; and I trust that the explanation of such requirements which I have offered to you this evening may be of service in making more widely known the special needs of the service, and in possibly stimulating the production of still more efficient and economical illuminating agents.

The supply of crude petroleum all over the world is very large, and, as the demand increases, the supply appears to be maintained; but should there come a time when the liquid petroleum resources show signs of exhaustion, the manufacture of paraffin can be continued, so as to supply the wants of the world for practically a unlimited period, seeing that bituminous shales exist in all parts of the globe in great abundance. It is much to be hoped that legislation will not do anything to cripple these important trades, but will allow full and free facilities for the transport and storage of all mineral oils which are admittedly safe for general use; but will, at the same time, in the interests of the general public, put such restrictions on the traffic in, and the use of, oils which give off dangerous vapours at temperatures below 100° F. (Abel test) as will prevent such oils being distributed all over the country for general use. In the Inflammable Liquids Bill of last Session, the distinction drawn between dangerous and safe oils did not appear to be so clear as it might be, and that the safe lighthouse oils as now used would have been subjected to the restrictions applying to really dangerous oils. It might perhaps be desirable to enact that every retailer of mineral oil should inform the buyer of the flashing point of the oil, for that is, without question, the one simple and intelligible test of its safety or otherwise. At the present time no one really knows what is sold over the counter as mineral oil.

It may be of interest to state that the samples of all oils submitted to the lighthouse authorities with tenders are subjected to severe tests to ensure only the very best quality of oil being supplied. The burning test lasts 16 hours without break, and no trimming of the wicks is allowed during that period. While the burning test is going on, photometrical observations are made after 4, 8, 12, and 16 hours, the mean of all being taken to indicate the real value of the illuminating power of the oil as burned in the test lamps. Of mineral

oils the specific gravity and flashing point are carefully ascertained, and each oil is subjected to fractional distillation to show the range of temperature at which the whole is distilled over, and the proportions distilling in uniform fractions between those limits. For paraffin the specified range is between 302° and 572° F.; for the heavy mineral oil a much narrower range is specified, viz., between 530° and 660° F. Further tests are made as to the oil remaining liquid at a low temperature; as to the effect of the 16 hours' burning on the wicks; as to the relative consumption, and a comparison with the sample of the oil accepted in the preceding year. When a contract is made for the oil supply every delivery under such contract is carefully tested to determine that oil supplied is in all respects equal to the sample upon which the contract was taken, and no oil is accepted which does not in all respects come up to the contract sample. When very high-priced mineral or vegetable oils were the illuminating agents for lighthouses, it was necessary to keep a strict watch on the expenditure. On the one hand it was requisite to ensure that a proper quantity of oil was used each night to maintain an efficient light; and on the other it was necessary to prevent waste, or possibly fraudulent dealing with so costly a commodity. Therefore a very elaborate system of accounting for every gill sent to the lighthouse was introduced, and is kept up to this day, although the value involved is very small now as compared with former days. The maintenance of a never failing supply of oil at each station is one of the most important obligations of the officers of the Lighthouse Boards, and to the credit of the service it may be stated that there is no instance on record of a lighthouse or a lightship having been unable to show lights at night through want of oil.

In the majority of cases the mineral oil is kept at the stations in tin-lined iron cisterns, but Sir James Douglass has in some recent instances recommended underground tanks built with rubble and cement, and lined with sheet lead. Such tanks are designed to contain at least twelve months' oil, and where they are constructed have given much satis faction.

The annual deliveries of oil to the stations on the English coast are made by the attendant steamers. One in particular is detailed for the mineral oil bnsiness. Consignments of varying quantities are made to be taken on board this vessel at different ports, and the small steamer takes to each lighthouse its annual supply. The work of delivering the oil is often delayed or made hazardous by the weather, and at the best of times is attended with much labour and difficulty.

In concluding my paper, I beg to say that the advantageous position now occupied by the authorities in respect to lighthouse oils is due mainly to the development of the mineral oil industry, through the enterprise of Mr. James Young, and those who encouraged and helped him in his early efforts; to the subsequent endeavours of those concerned in the mineral oil trade to meet the requirements for lighthouses, &c.; and to the desire of the lighthouse authorities, with their officers, to avail themselves at all times of new methods and improvements for the benefit of the important service over which they have control.

I must now thank you sincerely for your patience in hearing me, and ask you to forgive my many shortcomings. I have endeavoured to present the matter to you in a non-technical manner, and simply from the practical point of view, as affecting the service with which I am connected.

DISCUSSION.

The CHAIRMAN said Mr. Edwards had made this subject, although a technical one, extremely interesting. It was quite clear that mineral oils must in time beat the vegetable oils, on account of their chemical composition, the ingredients in the latter not being all combustible, but consisting of fatty acids and glycerine. Mineral oils, on the other hand, were nearly of the same composition as olefiant gas, the illuminating constituent of coal gas, with the addition of a little more hydrogen. They were therefore sure to win in the end; it was merely a question of manufacturing them safely. It was curious also that this was one of the oldest oils described in history, though it had been forgotten. It was only in 1846, when visiting one of the coal mines belonging to his brother-in-law, that he noticed this peculiar liquid pouring out of a portion of the strata, that it occurred to him it was worth investigating. In the Bible, and especially in the Apocrypha, this substance was constantly referred to, sometimes under the name of petroleum, *petri oleum*, the oil of the rock. When the spies were sent by Moses into the land of Canaan, they returned bringing wheat, grapes, honey, and oil flowing from the rock. Again, in the first chapter of 2nd Maccabees, there was an extraordinary account given of an experiment with petroleum. Nehemiah, after conquering the Persian territory, was anxious to find where the Priests of the Sun hid the sacred fire, and he offered some descendants of the priests a large

reward to show it him. They took him to a cave where there was no fire but a thick water, and he took of that water and poured it over the burnt sacrifice and filled the trenches round the altar with it. When the sun came from behind the cloud—(he did not mention the burning glass, but he must have had one)—the water took fire, the burnt sacrifice was consumed, and the water in the trenches was licked up. Therefore he called that thick water naphtha, which meant purification, and that was the origin of the word naphtha, which was still commonly applied to native petroleum or to the lighter portion of the distillate. It was frequently referred to under the name of thick water or rock oil, as when it was said, will the Lord not be satisfied with so many bullocks, and a river of oil flowing from the rock. It was also often called salt, as in the text, "Thou shalt not have a burnt sacrifice that is not smeared with salt;" the sacrifices being smeared with petroleum and set on fire. Again, "When the salt has lost its savour it is only fit to be trodden under foot;" but salt never lost its savour, and was never fit to be trodden under foot. But the salt of the earth, which was pretroleum, lost its essence by exposure, and left asphalte as the residue, which was made even in old times into pavements to be trodden upon. The Dead Sea is to this day locally called "Lake Asphaltites." The poor little spring of oil, which he introduced to his friend, James Young, and induced him to manufacture into burning and lubricating oil, soon dried up, but the industry then set on foot had grown to be very mighty indeed. From it had come not only a vast chemical industry in England, but it had led to the vast commerce in natural petroleum in America and Russia. It extended from the Caspian sea right away to the Himalayas, and there need be no fear of the supplies being exhausted. Baku was comparatively a small place, but the whole Caspian sea had petroleum beneath it, and sometimes it floated up to the surface, and could be set fire to. One day Mr. Young brought him, in great dismay, some of his oil, which—it being very cold weather—had become thick and turbid, and asked him what he should do, as the oil evidently would not keep. He said that must be the substance which Reichenbach described under the name of paraffin wax, and he asked him to get him enough of it to make a couple of candles. He produced it by freezing, though each candle cost £1, and he lit up his lecture room at the Royal Institution with those two first paraffin candles, and announced then that they would be the parents of a great candle industry. He was glad to say that his friend James Young died with an enormous fortune, which came chiefly from paraffin candles, for they paid much better than oil. Some years ago there was an Exhibition at Glasgow, and he found there a bust of himself in paraffin, which was very gratifying to him, as showing that the paraffin manufacturers had not forgotten the author of their industry. It was quite possible, by chemical means, to convert the lighter kinds of petroleum oils into heavy oils which would be quite safe; he had done it himself, and though it had not yet been done commercially, no doubt it would some day if it were necessary. This rock oil was no doubt used by the ancients for torches; because although you often read of candles in the Bible, candles were not then known, but torches were, and no doubt this oil was used for the purpose, and probably the first lighthouse ever put up—that on the island of Pharos—was illuminated by a fire kept up with asphalte and other combustibles, rock oil included.

Mr. Boverton Redwood said there was no doubt of the immense stores of petroleum in the world, which would last, probably, for centuries. Having had the opportunity of visiting some of the principal oil fields, he had been much impressed with the fact that up to the present time, notwithstanding the immense growth of this trade, we were probably only on the fringe of an infinitely greater development. Looking to the extent to which mineral oils were likely to be employed in the manufacture of illuminating gas, for the purposes of liquid fuel, and in other directions, this might really be termed the age of petroleum. Some of Mr. Edwards's observations with regard to the flashing point of these oils he must venture to call in question, because he understood him to adversely criticise the standard which had been adopted by the legislature, not only in connection with the introduction of the Abel test, but in the inception of the petroleum legislation. The system of testing first adopted was known as the open test, the flashing point in the open cup being 100° F. When the Abel system was legalised by the last Act, one of the most important points snbmitted to Sir Frederick Abel for consideration was the sufficiency or otherwise of the then existing test-standard. He had the honour of being associated with Sir Frederick Abel in some of his experimental work, and well remembered his expressing in his report a very distinct opinion that there were no grounds for considering that the minimum legal flashing-point was not calculated to afford adequate protection to the public; therefore, in fixing the new standard at 73° F., he avowedly did so because it was as nearly as possible the equivalent of the test which had hitherto been in use. A very elaborate investigation was also made in Germany, and when the Abel-Pensky system was adopted, which was substantially Abel's with a mechanical arrangement for the introduction of the light, the standard was fixed at 21° C., which was lower than the English standard. Again, when the subject of petroleum testing in India was being considered, the standard was fixed at substantially the same point as in this country, although the climatic conditions might be thought to require a higher standard. The definition provided that if the whole of the samples were of uniform quality, if none flashed below 70°, and the average was 73°, they might be passed as safe for use in lamps; if a single sample only were

tested, however, the standard was fixed at 78°. With regard to the relation between the flashing point and safety or danger in use, he was rather surprised that Mr. Edwards had not referred to the experiments made by the Commission in Berlin, or to those of Sir Frederick Abel and himself. Substantially it was found that a lamp might be said to be in the safest condition when the space above the oil in the reservoir was filled with vapour. If a lamp were of dangerous construction, having a free communication between the flame and the reservoir, and you tried to ensure safety by using oil with a high flashing point, you might have safety or you might have danger. Oil of a low flashing point obviously volatilised more readily, but that very condition tended to keep the upper portion of the reservoir charged with so much vapour that, even if the flame was communicated to it, there was simply ignition, but no explosion, for which a certain proportion of air was necessary. With an oil that volatilised more slowly, there was greater risk of getting an explosive atmosphere. For some years Sir Frederick Abel and he had, through the courtesy of Mr. Alfred Spencer, been afforded the opportunity of examining the *débris* of lamps with which accidents had occurred in the metropolitan district, and, where possible, the oil which had been used; and at a later date, in accordance with the desire of Colonel Majendie, they had made further investigations into lamp accidents. It was found that some of the most violent explosions occurred with oils of comparatively high flashing point, and the whole result was to confirm the conclusion previously arrived at, that safety could not be ensured by insisting on the use of high flashing oils only. With a dangerous lamp you might have an accident with almost any kind of oil; if the lamp were of safe construction, it would be next to impossible to have an accident with oil of any sort. He was not advocating the use of oil of extremely low flashing point, but the experience of 30 years had conclusively shown that the present standard of 73° F. was sufficiently high to insure the public safety. Mr. Edwards had given the result of a few experiments with different oils, but experiments were being made by the million every night, and the results of a few isolated experiments were not so convincing. It was quite possible to produce an oil which had a high flashing point, a low specific gravity, a high capillarity, which would flow and burn very well, and would not cause any abnormal heating of the lamp, but such oil could only be supplied in comparatively small quantities; and unless it could be shown to be essential to the safety of the public to have an oil of that description, it would be unwise to take any steps, by legislation or otherwise, which would have the effect of limiting the supply in that direction. He quite agreed with Mr. Edwards that there was no insuperable difficulty in manufacturing from American or Russian petroleum an oil suitable for lighthouse purposes; but it was necessary to take only a small fraction of the total distillate; and possibly it might answer the purpose of the Scotch refiner better to manufacture such an oil than the Americans and Russians. Exception had been taken to the definition of "inflammable liquid," in relation to lighthouse oil, in the recent Inflammable Liquids Bill, but it was worthy of note that this point was not raised when the Bill was under discussion, by specially appointed delegates of the trade, including representatives of Young's Paraffin Oil Company, the Broxburn Oil Company, and others. If the title of the paper had been rather more general, he thought there would have been a much larger attendance; but as regarded oils for lighthouse purposes, he had nothing but commendation for the manner in which the subject had been treated.

The CHAIRMAN having proposed a vote of thanks to Mr. Edwards,

Mr. S. S. BROMHEAD pointed out that the temperature in the lamps experimented on would vary according to the material of the reservoir. If it were of metal, the oil would get to a much higher temperature than if it were of glass, with a layer of plaster between it and the burner. They were all delighted to find that the Trinity Board had at last recognised the value of mineral oil, but he could remember, some twenty-five years ago, when the manufacturers pressed it upon them in vain, although the oil was even then in general use. An oil which was safe enough for domestic use ought to be safe enough for a lighthouse; and if the Board insisted on such a high standard that the manufacturers had to appropriate the cream of their product for this particular purpose, it would tend to lower the average quality of that supplied to the public at large.

The vote of thanks having been carried unanimously,

Mr. PRICE EDWARDS, in reply, said he had simply endeavoured to present the facts as they came under his notice as a public official; he had not attempted to deal very technically with them. He had the very highest respect for the opinion of Mr. Redwood, who had devoted the best part of his life to this subject, but he must repeat that what he had stated were simply facts; whether his experiments would be borne out by thousands of others he could not say, but they were conducted in a perfectly *bonâ fide* way. One gentleman had spoken in favour of glass for lamps; but others objected to glass lamps as being dangerous, because they were easily broken, and would allow the vapour to escape. If there were vapour contained in any receptacle at a higher temperature than the flashing-point of the oil, there was a source of danger; for it only needed to be liberated to inflame, or, if a flame got to it, to explode the lamp; and these facts, having come incidentally under his notice, he thought it his duty to mention them.

Correspondence.

DUST AND FRESH AIR.

I regret that my inability to hear in a large room prevented my attending the reading and discussion of Mr. Teale's paper. The closed ash receptacle under the grate has been used by myself for fully thirty years, by the simple expedient of bending a sheet of perforated polished brass to fit the front opening under the fire receptacle; and the addition to this of a strip of sheet iron between and behind the two lower bars of the fire, entirely prevents dust from falling on the hearth, making a perfectly clean, hot, and almost smokeless fire. Hundreds of copies of my arrangement have been made, and many are in use at the present time.

With regard to the use of velvet for the exclusion of dust, this has been used from time immemorial under glass shades; but its use for cupboards, &c., which are to be opened at intervals, however pretty in theory, is utterly impracticable, owing to the fact that it is impossible to obtain such wood as must be used in a condition which prevents its alteration in shape. For all important work of this class I use Spanish mahogany, which has been drying for ten or twelve years; but even this, if worked, or even planed, will begin again to alter its shape. When it will stop doing this I cannot tell, but I believe I am within the mark in stating that it does not settle down in another ten years, although it is pretty well acknowledged by experts that old Spanish mahogany changes its form less than any other wood known, and less than any artificial material which can be used in its place.

Our practice of opening every window in the house to its full width on all possible occasions, as an absolute necessity for keeping a house sweet and healthy, would hardly accord with the proposed system of controlled and limited ventilation; and, speaking from some experience, I should prefer the open windows and the "blacks."

The method of double glazing suggested is expensive, requires periodical attention, and is totally inapplicable to existing window frames. An equally good result can be obtained in ordinary window frames, by the use of two sheets of glass, set in with a putty, made by mixing whiting with what is known in the trade as "copal bottoms," *i.e.*, the thick waste from the bottoms of copal varnish casks. This putty is absolutely air and dust tight, making a perfect joint with the wood and glass, the latter having ample elasticity to provide for the expansion and contraction of the enclosed air. Any appreciable space between the sheets is quite unnecessary in practice.

It will be seen that I have traversed the same ground as Mr. Teale, with the essential difference that I have worked to existing conditions, and obtained the same result, at a very small expense, except the exclusion of "blacks' from the house; and, as regards any system yet invented, I may honestly say I prefer the "blacks" along with unlimited ventilation.

THOS. FLETCHER.

Warrington.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock:—

FEBRUARY 17.—Capt. F. E. YOUNGHUSBAND, "The Pamirs." General Sir GEORGE CHESNEY, K.C.B., C.S.I., C.I.E., will preside.

FEBRUARY 24. — ERNEST HART, "Ancient and Modern Art Pottery of Japan." Prof. WILLIAM ANDERSON, F.R.C.S., will preside.

MARCH 2.—Prof. VIVIAN B. LEWES, "Spontaneous Ignition of Coal, and its Prevention."

MARCH 9.—A. P. LAURIE, M.A., "Experiments on the Durability of Modern Pigments."

MARCH 16.—TEMPEST ANDERSON, M.D., "Iceland."

MARCH 23.—GILBERT R. REDGRAVE, "Manufacture and Industrial Application of Flexible Tubing."

FOREIGN AND COLONIAL SECTION.

Tuesdays, at Half-past Four or Eight o'clock; due notice of the hour will be given:—

FEBRUARY 16—LEWIS ATKINSON, "The Forthcoming Exhibition at Kimberley." The Hon. JOHN X. MERRIMAN, M.L.A., will preside. The paper will be illustrated by lantern slides. 8 p.m.

MARCH 15.—F. A. PEZET (Peruvian Consul General), "Peru." 8 p.m.

APRIL 5.—The Rev. JOHN McLEAN, D.D. "Manitoba and the North-West Provinces of the Dominion."

APRIL 26.—Sir EDWARD BRADDON, K.C.M.G., "The Progress of Australasia."

MAY 24.—Colonel HOWARD VINCENT, C.B., M.P., "The Extension of Colonial Trade."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

MARCH 3.—Surgeon-General Sir WILLIAM JAMES MOORE, K.C.I.E., "Indian Sanitation and the International Congress of Hygiene." Major-Gen. Sir OWEN TUDOR BURNE, K.C.S.I., C.I.E., will preside.

MARCH 24.—G. H. M. BATTEN, formerly of the Bengal Civil Service, "The Opium Question." Sir JOHN STRACHEY, G.C.S.I., C.I.E., will preside.

APRIL 7.—Dr. J. AUGUSTUS VOELCKER, "The Agricultural Needs of India."

APRIL 28.—Sir WILLIAM WEDDERBURN, Bart., "Reorganisation of Agricultural Credit in India."

MAY 19. — JERVOISE ATHELSTANE BAINES,

I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock:—

FEBRUARY 23.—J. WILLIAM TONKS, "Artistic Treatment of Jewellery: Jewel and Address Caskets." Sir PHILIP CUNLIFFE-OWEN, K.C B., K.C.M.G., C.I.E., will preside.

MARCH 29.—E. ROSCOE MULLINS, "The Decorative Uses of Sculpture." ALFRED GILBERT, A.R.A., will preside.

APRIL 12. — C. PURDON CLARKE, C.I.E., "English Brocades and Figured Silks."

MAY 17.—GEORGE J. ROBINSON, "Decorative Plaster Work" (II.). J. HUNGERFORD POLLEN will preside.

CANTOR LECTURES.

Monday evenings, at Eight o'clock:—

PROF. GEORGE FORBES, F.R.S., "Developments of Electrical Distribution." Four Lectures.

LECTURE IV.—FEBRUARY 15.—Generators of electricity by water-power and by steam obtained from destructors—General account of destructors—Hydraulic accumulators—Utilisation of local circumstances—Probable developments of electric distribution in the immediate future.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 15...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Prof. George Forbes, "Developments of Electrical Distribution." (Lecture IV.)

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. J. W. Grover, "An Explanation of the London Water Questiou."

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 1A, Adelphi-terrace, W.C., 8 p.m. Rev. J. J. Lias, "Miracles and Science."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Whitworth Wallis, "Wanderings in Sicily, the Island of the Golden Shell."

TUESDAY, FEB. 16 ... SOCIETY OF ARTS, John-street. Adelphi, W.C., 8 p.m. (Foreign and Colonial Section.) Lewis Atkinson, "The Forthcoming Exhibition at Kimberley, South Africa."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Victor Horsley, "The Brain." (Lecture V.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. A. H. Curtis's Paper, "Gold-Quartz Reduction Machinery."

Statistical, School of Mines, Jermyn-street, S.W., 7.45 p.m. Mr. L. L. Price and Dr. J. C. Steele, 'The recent Agricultural Depression as exhibited in the rental of an Oxford College, and the financial position of a leading London Hospital."

Photographic, 5A, Pall-mall East, S.W., 8 p.m.

Zoological, 3, Hanover-square, W, 8½ p.m. 1. Mr. F. E. Beddard, "Contributions to the Anatomy of the Anthropoid Apes." 2. Mr. A. G. Butler, "On a Collection of Lepidoptera from Sandakan, N.E. Borneo." 3. Mr. G. A. Boulenger, "Third Account of the Fishes obtained by Surgeon-Major A. S. G. Jayakar at Muscat, East Coast of Africa."

Asiatic, 22, Albemarle-street, W., 4 p.m.

WEDNESDAY, FEB. 17...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Capt. F. E. Younghusband, "The Pamirs."

Meteorological, 25, Great George-street, S.W., 7 p.m. 1. Mr. Edward Mawley, "Report on the Phenological Observations for 1891." 2. Hon. F. A. Rollo Russell, "The Untenability of an Atmospheric Hypothesis of Epidemics." 3. Mr. Henry Harries, "The Origin of Influenza Epidemics." 4. Dr. Ernest H. Cook, "Note on a Lightning Discharge at Thornbury, Gloucestershire, July 22nd 1891."

Microscopical, 20, Hanover-square, W., 8 p.m. Address by the President, Dr. Braithwaite.

Photographic Club, Anderton's Hotel, Fleet-street, E.C., 8 p.m. Mr. F. P. Cembrano, "Public Exhibitions."

Archæological Association, 32, Sackville-street, W., 8 p.m.

Civil and Mechanical Engineers, 7, Westminster-chambers, S.W., 7 p.m. Mr. R. Booth, "Gas Producers."

Inventors' Institute, 27, Chancery-lane, W.C., 8 p.m.

THURSDAY, FEB. 18...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. Percy Groom, "Bud Protection in Dicotyledons." 2. Mr. F. Stephani' "Revision of Colenso's New Zealand Hepaticæ."

Chemical, Burlington-house, W., 8 p.m. Mr. Horace T. Brown, "A Search for a Cellulose Dissolving (cyto-hydrolytic) Enzyme in the digestive tract of certain Grain-feeding Animals. 2. Prof. Tilden, "Limetbin."

London Institution, Finsbury-circus, E.C., 6 p.m. Prof. Vivian Lewes, "Illuminating Flames."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. E. Ray Lankester, "Some Recent Biological Discoveries."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m.

Historical, 11, Chandos-street, W., 8½ p.m. Annual Meeting.

Numismatic, 22, Albemarle-street, W., 7 p.m.

FRIDAY, FEB. 19...United Service Institution, Whitehall-yard, 3 p.m. Major C. F. C. Beresford, "The Telephone at Home and in the Field."

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m. Prof. Percy Frankland, "Micro-Organisms in their Relation to Chemical Change."

Philological, University College, W.C., 8 p.m.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Physical, Science Schools, South Kensington, S.W., 5 p.m. 1. Annual General Meeting. 2. Prof. S. Thompson "Supplementary Colours," and 3. "Modes of representing Electromotive Forces and Currents."

Geological, Burlington-house, 3 p.m. Annual Meeting.

SATURDAY, FEB. 20 ... Saturday Lecture Society, Lecture Theatre, South Kensington Museum, S.W., 3 p.m. Rev. G. F. Browne, "Early Christian Art." (Lecture II.)—Scotland and Man.

Royal Institution, Albemarle-street, W., 3 p.m. Lord Rayleigh, "Matter: at Rest and in Motion." (Lecture II.)

Journal of the Society of Arts.

No. 2,048. Vol. XL.

FRIDAY, FEBRUARY 19. 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CANTOR LECTURES.

The fourth and concluding lecture of the course on "Developments of Electrical Distribution" was delivered by Professor George Forbes, F.R.S., on Monday evening, 15th inst.

On the motion of the Chairman, the thanks of the meeting were voted to Prof. Forbes for his course of lectures.

The lectures will be printed in the *Journal* during the summer recess.

Chicago Exhibition, 1893.

MEETING OF THE ROYAL COMMISSION.

A meeting of the Royal Commission was held on Wednesday, 17th inst. Present: The Attorney-General, M.P., in the chair; Sir Frederick Abel, K.C.B., D.C.L., F.R.S., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Sir Frederick Bramwell, Bart., D.C.L., F.R.S., Michael Carteighe, R. Brudenell Carter, F.R.C.S., Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., C.I.E., Professor James Dewar, M.A., F.R.S., Major-Gen. J. F. D. Donnelly, C.B , Sir Henry Doulton, Sir Douglas Galton, K.C.B., D.C.L., F.R.S., C. Malcolm Kennedy, C.B., J. Fletcher Moulton, Q.C., F.R.S., Sir Owen Roberts, M.A., F.S A., Professor W. C. Roberts Austen, C.B., F.R.S., with Sir Henry Trueman Wood as Secretary.

TEXTILE COMMITTEE.

A meeting of the Committee on Textile Manufactures was held on Friday, 12th inst. Present:—Mr. Charles Malcolm Kennedy, C.B., Chairman of the Committee; Mr. J. D. Barbour (Belfast); Mr. C. E. Bousfield (Leeds); Mr. Frederick Ellis (Dewsbury); Mr. William O'Hanlon (Manchester); Sir Owen Roberts (Clothworkers' Company); Mr. Thomas Wardle (Leek); and Sir Henry Trueman Wood (Secretary of the Royal Commission).

ELECTRICAL DEPARTMENT.

The following circular letter from the Chairman of the Electrical Committee has been issued:—

Society of Arts,
John-street, Adelphi,
London, W.C.,
February, 1892.

Gentlemen,—The Electrical Committee are anxious that the Electrical Department of the Exhibition should contain a good representation from this country.

The British exhibit will include a historical collection as well as the contributions which will be sent in by commercial firms. In addition, it is hoped that a portion of the electric lighting of the Exhibition may be carried out by some British firms, and the Committee think that the arrangements of a complete lighting station on the English method could advantageously be shown at Chicago.

From the English point of view it is specially desirable to show how large a share English electricians have had in developing electrical science and its practical applications. The first electrician was an Englishman, Gilbert. It was in England that a practical telegraph line was first worked out by Ronalds in 1816. There are no names more closely associated with the early development of the science of electricity than those of Davy and Faraday. The introduction of telegraphy must inseparably be connected with Cooke and Wheatstone; while the early history of the dynamo would be incomplete indeed without reference to Wilde and Holmes.

In England, electricity was first applied to the working of railways, and here nearly all the submarine cables of the world are made.

It is hoped that arrangements may be made for showing the fine collection of historical apparatus in the possession of the Post-office, and this will be supplemented by contributions which will be sought from many other sources.

On the commercial side, whilst there is no disputing that practical electric lighting has made greater progress in America than in this country, there is yet much that England can show electricians on the other side of the Atlantic. The domestic uses of electricity, and its artistic application, are matters in which they confess themselves to be less than we are; and probably many firms who make this a speciality will find it to their interest to show in the Exhibition electrical fittings and the manner of their application.

It is especially to be remembered that the Exhibition will be visited by numbers of foreigners, and especially by many persons from our own Colonies; and it is important that English electricians should not miss this opportunity of strengthening and increasing their hold on Colonial trade, since it is quite certain that a strenuous effort will be made by American manufacturers to get this important source of revenue into their own hands.

Another department in which the United States exhibit will certainly be deficient is that of electric railway signals. The methods on which American railways are worked, do not, as is well known, require the very complete system of signalling apparatus employed in European countries, but this system is now being introduced into America, and will probably supplant the methods now in use. There is, therefore, a very favourable opportunity for manufacturers of this class of apparatus to bring themselves before the notice of American customers.

Another important department which ought not to be neglected is that of electro-metallurgy. Here also English inventors will probably find it to their advantage to bring their inventions under the notice of American metallurgists.

A special building in Jackson-park will be devoted to the Electrical exhibits. The size of this building is 700 feet by 350 feet, enclosing an area of 250,000 square feet. The space provisionally allotted to Great Britain in the building is 20,000 feet.

It is understood that all the buildings as well as the grounds will be lighted at night.

Applications for space in the British Section must be made upon forms to be obtained from the Secretary of the Commission, Sir Henry Trueman Wood, at the Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, not later than February 29th, 1892, and addressed to the Secretary as above.—Yours faithfully,

W. H. PREECE,
Chairman of the Committee.

RAILWAY COMMUNICATION.

At the meeting of General Managers of British Railways, held at the Clearing-house on Thursday, the 11th inst., it was decided that the railways would carry goods for British exhibitors at the Chicago Exhibition, to and from the port of shipment, at half rates. The American railways will charge their usual rates to Chicago, but will bring back the goods free at the close of the Exhibition. Many of the principal steamship companies have reduced their rates considerably, and will take freight for the Exhibition at 11s. per ton. Many of them have also consented to adopt a reduced passenger tariff for exhibitors and their *employés*, certified as such under the authority of the Royal Commission.

CANADIAN COMMISSIONER.

The Canadian Government have appointed Mr. William Saunders Commissioner for the Dominion of Canada at the World's Columbian Exposition.

The word "Praxiteles" has been registered at the General Post-office as the telegraphic address of the Society of Arts, and of the Royal Commission. Telegrams may therefore be addressed "Praxiteles, London."

Proceedings of the Society.

INDIAN SECTION.

Thursday, February 11, 1892; Lieut.-Gen. Sir ANDREW CLARKE, G.C.M.G., C.B., C.I.E., in the chair.

The paper read was—

RECENT TRAVELS IN INDO-CHINA.

By LORD LAMINGTON.

The kingdom of Siam, lying as it does off the track of the chief line of steamers, is a country not often visited by Europeans; but this will be changed, as the last five or six years have witnessed a considerable increase in the number of European traders. It may be assumed that once the globe-trotter realises he can see Oriental life with most of its essential characteristics retained, he will not grudge the four days spent in going from Singapore to Bangkok.

The chief part of the town lies on the western or left bank of the river, but its originality is being destroyed by the construction of roads and houses partaking of European design. It is on the other bank where locomotion is only possible by boat through a network of intricate canals, embowered by tall palms, ferns, and bamboos, that it might be well entitled the Venice of the East. The houses, almost hidden in the jungle, are of bamboo, built on piles to raise them above the mud. For that matter all the houses in Siam and the Shan States are raised above the level of the ground, and are entered by ladders. A large population live in house-boats moored to posts on either side of the river.

I witnessed some of the Royal processions, both by land and on the river; the former are curious from the quaint old dresses that are intermingled with the modern uniforms of the

naval and military forces; the water *fêtes* are fascinating from the many long canoes that take part in the display, and which are propelled by some seventy men, whose gilt paddle blades glisten in the sun. The whole scene is one of gorgeousness and splendour. The King, with his crown on and in his robes of State, sits on a high throne under a golden canopy in the largest canoe. At night, too, the river illuminations are like a fairy scene, and at all events in one respect differ from our Crystal Palace displays, as some of the fireworks in Siam are musical.

I spent a pleasant fortnight in Bangkok, and was received courteously by the King. Though the Europeans there affect some indifference if not contempt for all that is to be seen in Bangkok, to the ordinary traveller there is much for him of interest in the manner of life of the people. It may be some consolation for those who in this country deplore the degeneracy of our times, as marked by strikes and the difficulty of getting good servants, to know that in Bangkok a row of houses have long remained in an unfinished state owing to a strike of the Chinese, and that the second is a grievance which is constantly aired.

I left Bangkok in the *Chow Phya*, a stern-wheeled steamer, owned by a British Company, which runs, so long as there is sufficient water in the river, as far as Paknam Po. The river bank was fringed with bamboos, and amid them houses, or rather huts, now and again showed themselves. At the back of these houses are extensive paddy plains. Teak and paddy are the two great articles of Siamese trade; and, for either of these, a dry season like the one they had last year means serious loss. The dryness affects the teak, in that the logs cannot be floated out of the forest down the creeks; and even in the river the shallows are so numerous that the cost is enormously increased by the labour of working them down. After the first two days, the steamer was constantly grounding. Then arose a wild scene of confusion. The steamer chiefly pays by towing up empty rice-boats; these are astern, in four lines, with perhaps from four or five boats in each.

As soon, then, as there is a sudden check, or when rounding a sharp bend of the river, the boats dash and grind up against one another, or against the bank, the family on each boat yell and shriek, and jump on to the roof, made of bamboo and plantain leaf, endeavouring to avoid the danger of being swamped and crushed.

We took four days to reach Paknam Po, the river banks being monotonously flat all the way. I here changed into a boat provided for me by the Chinese agent of the Borneo Company. I took charge for him of some money that was needed by other agencies up the river; nor was he sorry to be quit of it, being always fearful of being robbed. As a matter of fact, robberies occur only between the natives, and an attack on a European is unheard of. This Chinaman described the people as very apathetic and indifferent as to who their rulers might be. Their only dread is of compulsory service, to which, in addition to a regular annual amount, they are always liable to be called on to do. One instance was related to me of how a certain town was named to supply men for military purposes, but the people heard of this, and the whole male population discreetly vanished into the jungle.

When a prince is on his travels, every district through which he passes is called on to supply him with food and transport, and it is not uncommon if the news gets wind for the owners of boats to request a European to take temporary charge of them. Much as the people dislike this system, they evince no desire of working for themselves. This is to be partly accounted for by the impossibility of their retaining money in their own possession, if once it becomes known that they have any laid by—for the practice of farming the taxes naturally results in great oppression—and partly because the ease of living renders them careless as to the future.

When I was ascending the Meping, I experienced the greatest difficulty in obtaining boatmen, despite the liberal pay, and the fact that they might otherwise at any moment be called upon to work for some chief without reward. On one occasion a traveller to Chiengmai found that the crew whom he had engaged had paid substitutes to do their work, while the latter in their turn hired others; and thus packed away in one small boat were three crews, one of whom alone worked. The boats are covered in, and can be made very comfortable. A crew is usually composed of four men. They punt the boat, pressing the bamboo pole into the hollow of the shoulder, with their bodies bent double. The men are almost always Laos, and are capital workers when once they start. They are all tattooed about the middle, and often dispense with garments altogether. These tattoo marks are beautifully executed, and by

these markings, the Laos to the west of the Mekong acquire the title of "black-bellied," those of Luang Prabang, who are only now beginning to adopt the custom, have hitherto been known as "white-bellied." They have no hair on the face, unless it be a moustache resembling a scraggy tooth-brush, and their heads are shaven except on the crown, where the hair bristles straight up as if astonished at the extraordinary countenance below it. Cheap German looking-glasses beguile a great part of their time, as they gaze at their faces and carefully search for any hairs showing where they should not be. The men are amphibious, tumbling out of the boat on the smallest provocation. It was interesting to see raftsmen bringing down teak rafts. On a high scaffolding a man would watch for any shallows or obstructions, and give orders accordingly to the others. Some would be poling; but one man in the water behind, with a pole attached to the raft by a long rope, would, as soon as a particular direction were pointed out, swim off, and then planting the pole firmly into the river-bed, the rope would gradually tauten and the raft swing round on this extemporised pivot.

At Raheng I paid a visit to the Governor, but the interpreter not turning up our conversation was strictly limited; however he returned the visit in the afternoon under more favourable circumstances, bringing with him a present of a pig and chickens. Though I was only staying at the other end of the town or rather long straggling village, he had never before been such a distance. The main street was difficult to ride through without one's feet damaging the eggs or other commodities exposed for sale in the shops, whilst overhead bamboo shutters to keep off the sun gave unpleasant knocks on the head.

I continued my journey up to Chiengmai, and on the third day was making slow progress up the rapids. The delay was compensated for by the fine scenery; rocky cliffs of great height bordered the river, and every niche where a tree could find place for its roots was filled by some specimen of forest life. The worse rapids had to be surmounted by towing, at which all assisted. My own dress was adapted for getting wet, as it only consisted of a shirt and a short native skirt or sarong, and no boots or socks. Once the rapids passed, the villages became again more frequent; in some of them were deliciously sweet smelling flowers. There is an ingenious water-wheel used for irrigation purposes, and as it turns, instead of making a creaking noise, low melodious sounds are produced. The blades of the water-wheel are fashioned out of split bamboo, set at such an angle that they hold the water caught in going round till they reach the highest point of the circle, when the water empties itself into another bamboo projecting from the bank, thence it is conveyed and distributed wherever required.

After nearly a three weeks' journey I reached Chiengmai, the capital of the Laos country. Its population is put at 20,000, but I consider that a very high estimate. The inner town is surrounded by a high wall, in which are temples and houses with large compounds. The market is most varied, and the Laos graceful and charming to look at. Their dress consists of a longish petticoat with many horizontal stripes of different colours, a yellow shawl is thrown gracefully over the bust, and their hair, done up in a knot, is usually decorated with flowers. The American missionaries, who have established themselves here, enforce upon any converts they may make the wearing of tight-fitting white jackets. The effect is most ungraceful; and, if the senses are exercised in any way, I am sure it is not in the one desired. The people are themselves most modest, and this act of Mrs. Grundyism can only be to create in the mind suggestions which had no existence before. A new wooden bridge connects the two banks, but it was a matter of debate whether it would stand the floods, with teak logs crushing up against it. This is one of the very few bridges in the country. It is lamentable to see, both for the interests of the country and for the travellers' comfort, how the so-called trade routes are the veriest tracks in the jungle, made yet more difficult by the deepest muddy holes, boulders, fallen timber, and any other conceivable obstacle.

The Chief of Chiengmai gave me a representation of one of the Laos plays, followed by some of the national war dances. The performers are, in every case, women, and of his harem. They don't speak, but only act by gestures. This is chiefly done by the working of the wrists and hands. Their dresses are magnificent. The band do the chorus, and tell, or, more strictly speaking, relate the story. The musical instruments are very varied, those fashioned of strips of bamboo, stretched across a wooden framework, being, in my opinion, most silvery-toned and melodious. After a feast, I finished up the

evening by playing a game of cards called "pok," something of the nature of *vingt-et-un*. Some of the wives played, and apparently any of the public who liked to could join in. The faces of the natives whilst playing were a study of immobility.

Some description of the political position of the country would not be out of place, for Great Britain, of all European powers, has by far the largest interests at stake in Siam. She carries on the bulk of the trade in Bangkok; and hitherto at Chiengmai the only firm that has an agency there is the Borneo Company. Moreover, there are thousands of British subjects in the country. In Siam proper there are Malays, Chinese, and Hindoos; in Laos there are Burmese and Shans. These altogether number several thousands, and it is for their protection that we have a consul at Chiengmai, who, by treaty, has partial powers of jurisdiction in cases in which they are concerned, though it is a matter for regret that he has not equal powers as the consul at Bangkok. Our frontiers, which have been extended by our now holding all the old kingdom of Burma, are in course of arrangement with Siam; in fact, except for a comparatively small distance on the north, they have been practically agreed to. Laos territory used to merely own the suzerainty of Siam, but the latter is now imposing her authority to a much greater degree, not entirely to the satisfaction of the Laos. No doubt, however, Siam is wise to try and consolidate her tributary States. The French idea is to retrieve in Indo-China another India. Consequently every year sees them pushing on from Tonquin and the Annan coast. The very least they seek is the Mekong as a frontier, and for this no other authority need be quoted than that of M. Ribot, the Minister of Foreign Affairs, who recently made a statement to that effect in the Chamber. The new Governor-General of Tonquin, M. de Lanessan, in his work on Indo-China, considers the watershed between the Mekong and Menam rivers as the proper frontier. There is not the slightest validity whatsoever in any of these claims, but every year sees fresh expeditions being sent out for purposes of survey, commerce, or any possible excuse. The Mekong has been ascended last year by steamer as far as the first rapid, and its uselessness as a waterway has been fairly proved. This will not deter the French from including Luang Prabang as a possession, nor is it likely that any opposition would be offered, though there was a talk of the Siamese venturing to offer fight. It may be well asked what the French expect to gain, as the "hinterland" of the Annam coast to the Mekong is decidedly of a poor nature, unless it has mineral wealth. The answer, then, is that they expect to be able to put goods into Chiengmai, by way of the Black River, cheaper than the British can from Bangkok, or the Panthay traders from Burma. The idea is ludicrous, but that was the way in which the French accounted to me for their policy; if it is not that, they must have other and grander intentions.

To resume my personal narrative. Mr. Archer was about to take charge of a frontier survey mission, and I took advantage of his kindness to travel with him. I had to secure the services of a party of Panthays and their mules to take my baggage. These Panthays are Chinamen who had been driven out of Yunnan for rebellion, some few years ago, and had settled in Burma, carrying on trade, in the dry season, by caravan. They were fine tall men, and hardy. The way of loading their mules is peculiar; the baggage is strapped rigidly with long leather thongs on to a tree or trestle, and must be so adjusted that the weight on either side is equal. This is then lifted up by two men and placed on a pad on the mule's back, without any further fastening, and keeps its place by balance. This is the reason why the weights on either side must be carefully adjusted. After several trifling *contretemps*, we left Chiengmai on December 10th, 1890, and, in eight days, reached Meung Tuen. The country we went through was perpetual jungle, except on the rare occasion of passing through the paddy or rice fields of some village. If there were the population to work it, the area of cultivation might be vastly increased, and, from the dense wood on the hills, it may be imagined that the whole of the country might be rendered productive. We saw a certain amount of teak, but this, wherever it can be worked to a profit, is fast disappearing before the axe of the Burmese forester, and there are no attempts at replanting.

At Meung Tuen the escort and survey officials joined us from Burma; they had been suffering a good deal from fever. We were now a large party, as there was a Siamese representative and his escort. Subsequently, we were joined by a Laos Commissioner, and also a representative from Kyangtou, one of the Shan States.

Our course lay eastwards, over the divide

between the Salween and Mekong water-systems. As often as not the route took us up the bed of some stream, overhung by creepers, wild plantains, and the general wide luxuriance of tropical growth. Tiger and deer were plentiful, also monkeys. Birds might be heard flying away, but all animal life, from the density of the jungle, was rarely seen.

In three days we reached Meung Sat; the greatest elevation we had been over was about 3,300 feet, the altitude of the cultivated valleys being usually about 2,200 feet.

Meung Sat is a very small village, The plain is extensive. The Mekhok, a fine river some 60 yards broad, flows on the eastern side. The cold mists in the morning made us shiver, the thermometer registering 44°. This does not sound chilly, but the change after the heat of the day, when it was 88° or 90°, was trying.

The Musea tribe, who live on the hills, occasionally visited us, anxious to see the "lords of gold and silver." They live in the most secluded parts of the mountains, never allowing a stranger to approach their villages if they can help it. Otherwise they are nice, open-faced, little people, extremely expert with the cross-bow and arrow. They carry some of the latter poisoned in case of any danger. In every party of these people I came across, one or two of the number carried musical instruments in the form of a hollow gourd, in which are five bamboos; holes are pierced for notes. The music is soft, but melancholy. Our further route lay down the left or opposite bank of the Mekhok, and on January 1st we reached the village of Na Mon, which no white man had previously visited.

The antagonism of interests for the last decade has made the neighbourhood by no means safe. The outpost villages on either side were inhabited by men whom a sense of constant danger had made somewhat callous to the right of property. There was consequently nothing but an ill-defined foot-track, and even this had been unused for a year after the burning of Meung-Yon and Wying Chè villages by the Siamese last year. We had, therefore, to cut, and in a good many places to dig, our own road, for not far short of a hundred miles in all, extending on either side of Wying Chè. This resulted in a very serious loss of time, but as a compensation it induced the former inhabitants of the destroyed villages to return and rebuild their old houses, so that the line is now likely to be kept open. From a distance of about twelve miles below the town of Maingthat, as far as Ta Ton, the Namkôk runs in a narrow channel between hills, and the stream is rendered quite unnavigable by constant rapids, of which the chief is Kyeng Haö Wyen. This is the point at which the Siamese claim that their frontier crosses the Namkôk.

Phya Pap, the celebrated rebel against Chiengmai, was the immediate cause of the destruction of the Viang-Ké group of villages. After the failure of his projected rising at Chiengmai, he proceeded to Kyangton, where, attracting to himself some of the floating bad characters who are scattered about the Shan State, he marched south, and occupied Meung Fang. The Chief of Meung Fang was himself engaged on a questionable enterprise against a State whose destiny, whether to be under our protection or that of Siam, had not been decided; but he quickly returned to his capital, and, driving out Phya Pap, pursued him across the Meh Kok, and, on the ground that the Shan villages on the north bank had given assistance to the rebels, burnt them; hence the general devastation. The mission was running short of supplies, so I, with a large detachment of mules, went off to Meung Fang to try to get provisions. The Chief was, in consequence of his former conduct, greatly afraid of us, and tried to keep away; but I routed him out, and got him to give orders that rice, chickens, &c., might be sold, for, without his permission, the people did not venture to trade with us. The plain of Meung Fang is a rich possession, and of great extent.

On my return to Viang-Ké, we were further detained by the non-arrival of Mr. Kennedy, who had met with some difficulties with the hill tribes whilst foraging. At length, to the relief of our anxiety, he returned, and we travelled in a north-easterly direction to Ban Meh Chan.

The country, including the site of the old and large town of Viang-Ké, is covered with impassable cane-brake. The number of tigers is, therefore, very great; and, until we left the Namkôk, there were alarms in the mule and bullock camp every night, and sometimes several times in the same night. No mules were taken, but several bullocks were carried off. The density of the jungle secured the safety of the tigers. From Meungngam, the road leads gradually up to a double ridge, the highest of which is 2,750 feet above the sea-level. The ascent and descent are very gradual, and the roads, under ordinary

circumstances, and with regular traffic, would be very easy. It had, however, been almost totally disused for many months, with the result that we marched mostly along stream beds, and by-paths, cleared for us by working parties, through interminable stretches of giant bamboo. At length we entered the western fringe of the great Chieng Sen plain; but, although there were abundant signs of former cultivation, no inhabitants were met with until we reached the Laos villages round about Ban Meh Chan. Just under the hills, at Pung Pen, there is an extensive area of hot springs. There is a considerable deposit of sulphur, and the air was heavy with the smell of sulphuretted hydrogen. The water bubbled out from fissures of a reef of rock, and in at least one place spurted out in a spray to a distance of two feet. We had no apparatus for testing the temperature, but it seemed to be very close on boiling point, and, in the early morning, heavy masses of steam rose from the marsh formed below the springs. A still more singular circumstance was the existence of similar springs of hot water in the bed of the Me Chan, which flows a short distance to the south. The stream is quite deep enough to suggest a bath, and the springs in its bed are quite hot enough to the bare feet to cause the bather to jump.

Our route lay under the abrupt precipitous ridges, which marks the western boundary of Chieng Sen. Kyaington villages have crept down under this range, and are stationed on the upper waters of nearly all the rivers here, as far down as the Mè Sair. Close to the sources of the Mèh Tham, which flows out of a cavern at the foot of a sheer cliff, are two fine caves high up in the face of the precipice; inside both are shrines, pagodas, and images, which seem now-a-days to attract few worshippers.

At Honglük we were again in the Shan country; the plain which we had been traversing formed the principal point of inquiry for the Commission, and from the want of any strong natural feature it will be hard to define the boundary.

As I wanted to enter Tonquin through the Siboong Pana, a route which no European had hitherto travelled, I with great regret bid farewell to my friends of the Commission to go on alone. This was by no means agreeable to my mulemen, who were afraid of going into a new country. However, extra pay tempted them, and I left on February 1st.

On the way to Chieng Lap, we passed by Meung Len, 21½ miles distant from Honglük, on the north side of the stream named after it, and in the centre of a very fine plain. It was the largest and most flourishing place I had seen in the Shan States.

There are some fine brick monasteries, and I saw a man smelting and working silver, amid the houses that form the apology for a street, a woman working primitive bellows, made of two bamboos, and a feathered piston. The Nam Zen is just fordable, and no more, at this time of the year, when it is at its lowest.

It was a little below Chieng Lap that Garnier, in ascending the Mekong, had to forsake his boats and contiuue his journey by land along the right bank. Even here, some 1,500 miles from its mouth, the Mekong is a noble river. The natural bed would be about 600 yards wide, but where I crossed it was not more than 80 to 100 yards, very deep, and flowing between jagged rocks that protruded out of the sandy channel. A raft was fashioned out of two canoes and a bamboo platform to ferry over me and my belongings. This was not done, however, before some tapers had been burnt to propitiate the devils, and a sacrifice of rice, nuts, and a rupee offered up on the rocks. I was unaware of the ceremony till it was too late to see it. The eastern or left bank of the river is Chieng Kheng territory. We had to descend it for some six miles, marching over the burning sands of the broad river-bed.

Here the Nam Ma flows in, and during the rains its current is so violent, and the volume of water so great, that the passage of the Mekong by travellers going either east or west has to be made below the mouth of the Nam Ma. On a high bank in the angle, formed by the bend of the Mekong, is the site of the ancient city of Viang Kôk. As usual, no sort of idea could be obtained when this city ceased to exist. The ramp and the moat could still be traced, though choked with jungle; and the place must have been of considerable size, and commanding, as it does, two reaches from the one front, must have been of some strength. The whole country from here to the neighbourhood of Meung Long is deserted, and the land itself so nearly flat, with only very gentle undulations, that practically the whole area could be brought under cultivation by irrigation from the Nam Ma, the Nam On, and the Nam An. Meung Long lies in a flat valley, or, rather, a strath, along the banks of the Nam Ma. It is the beginning of the long plain, as it might be almost termed, which

runs up to Meung Sing, and past it, on to Meung Phong, is Chieng Hung territory. It varies in width from a mile or two at Meung Long and Meung Kang, to five or six at Meung Sing, and eight to ten at Meung Phong. Each of these townships is separated from its neighbours by gently sloping ridges from 100 to 200 feet high and covered with dense forest. Otherwise the plain is unbroken, and the existing clearing for paddy cultivation might be enormously extended without any other labour than that of clearing the jungle. To the west a high range growing steadily higher northwards separates the strip of plain land from the Mekong, and to the east hills tower up to heights of 6,000 or 7,000 feet, shutting off the Siamese territory so completely that there is absolutely no regular communication except perhaps toilsome tracks from one village to the other. The gradual resettlement of the Trans-Mekong country drew the chief town eastward to the ancient town of Kyang Kheng on the left bank of the river, and from there the present Chief on his accession moved further eastwards to Meung Sing, no doubt as a precautionary measure against possible attacks from Kyangton. Chieng Kheing is by rights tributary to Kyangton, but the Sawbwa of the former was offended that his nephew should have been made chief of the latter State, and at our recognition of his nephew's claims. In his anger he had placed himself under the protection of the Siamese State of Nan. As Kyangton was one of our protected Shan States, I could not be sure what reception the Sawbwa of Chieng Kheng might give me, no European having ever visited the place. I, therefore, advanced with caution, and sent on my two interpreters to ask for camping ground: my whole party only numbered eight persons. Everything passed off satisfactorily, and I paid a visit to the Chief, a kind, portly old gentleman, and most anxious now to return to his proper allegiance.

Except rice, coffee, opium, and a small amount of tea, which is more cultivated as one goes north, till the tea-gardens of Ibang are reached, there is no produce of any value in the State, sugar-cane and tobacco being only grown for personal consumption. This, however, is only because the land has not its resources developed, and requires better means of communication. Otherwise it is decidedly fertile, and, I should say, has a larger population than exists in adjoining regions. In my opinion, it is highly important that our Government should not shrink from accepting the allegiance of this State. The responsibility is insignificant compared with what they incurred when they took on Kyangton, the capital of which, under favourable circumstances, is a month's march from their nearest military post. At present, the frontier rests on the Mekong; and a river is always an undesirable frontier, more especially in this case, when, by crossing over, there is a mountain range, with no path fit for even pack animals from between Meung Sai, in the south, till north of the parallel of Chieng Hung. This would form an excellent line of demarcation between us and the French, and no one with any knowledge of that country would deny that the day must come when we and the French have conterminous frontiers, for they will advance till they meet us. Moreover, we should, from our position, be giving moral support to that portion of Nan lying on the east bank of the Mekong, and we should ourselves be holding a commanding position in the fertile districts of the upper part of that river. The Government, by accepting what is offered them, would acquire what I consider to be of utmost value to our interests.

I left Meung Phong, one of the towns of the Sibong Pana, held to be the richest and most fertile region in northern Indo-China, thence on to Meung La, where, finding a due easterly course to the Black river was impossible, I had unwillingly to go south-easterly to Meung Sai. The difficulty of obtaining information was very wearying. Descriptions of the route were never reliable for more than two days' journey ahead at the most, and drawing maps on the ground was the only method at getting an idea of the relative distances between places.

We were disturbed on one or two nights by dacoits taking our mules. We were, however, always successful in retrieving them. The people generally were most friendly, and extremely interested in all my possessions. When it happened that I camped near a village, the whole population turned out to gaze in wonderment at my eating with a knife and fork. The hill tribes, of whom there are many varieties, are timorous. They live hardy lives, wandering about as the soil on the hill sides becomes exhausted by the crops of paddy.

I passed the salt wells of Baw Hay and Bawlun. This salt forms an important article of commerce, and the Panthay caravans load up with it on their return westward journey. The village chief endeavoured to prevent my visit-

ing the wells, being afraid that the presiding spirit would be annoyed at seeing a stranger. They themselves never venture near in either black or white clothes.

Here the hill tribes are mostly Yao Yin. They have the neatest and most intelligent appearance of all the hill people, and bear a closer resemblance to the Yunnanese. The women have a light complexion, and wear a loose kind of Turkish trousers of very finely embroidered silk, a long loose coat, and numerous silver ornaments. On ceremonial occasions, they wear an extraordinary head-dress of red cloth stretched over a stand about six inches above the head, and about two feet long and one broad.

A monotonous thumping sound attracted my attention to a novel rice-pounding machine in use about here. Water is led through bamboo pipes into a hollow cut into one end of the rice-pounding pestle, which I had hitherto always seen worked by foot, the pestle then rises with the weight of water at the other end, the water is automatically discharged, and the pestle falls back and pounds the unhusked paddy.

At Meung Sai I was in Luang Prabang, or Siamese territory; thence the hard travelling began. Pack animals never go beyond Meung La. I had to take a path along the crest of the hills on the left bank of the Nam Pak. Some of the ascents were, I feared, impossible for loaded animals, and the narrowest of tracks on precipitous slopes, often blocked by fallen timber, made our progress slow, though I had several natives cutting a way. When we again reached the Nam Pak, I put the luggage on rafts and allowed the mules to scramble along the banks as best they could. My mulemen were now complaining of the hardships of the road till on March 4th we reached the westernmost French port, called Dien Bien Phu. It was pleasant to see once again a European, of whom there were three here, and a half company of Annamite troops. The road now to Lai Chau on the Black River had some pretence to the title of a road, our only mishap being an onslaught of tigers on our mules. The country was very unhealthy, and though the soil of the plains is undoubtedly fertile, the villages look poor. But then, till recent times, the country has always been terribly devastated by warfare. The Black River is well named, as it flows through deep gorges. Lai Chau, though marked with big letters, is only of importance as a military post, the native houses numbering some half-dozen. Here I left my retinue and mules, except a faithful Chinese interpreter. My voyage was now in a long, uncomfortable, narrow boat, and the three or four days I spent in reaching Chobo would have been most monotonous except for the excitement of shooting the rapids.

Some six weeks previous to my arrival dacoits had attacked Chobo, three Frenchmen had been killed, and the place burnt; the marks of bloodshed were yet visible. It was now re-occupied by the French; but I had to take an escort for my further journey. At Tuvu, opposite to the curious rocks on the right bank, called—from their resemblance to the church—Les Rochers de Notre Dame, great excitement prevailed, owing to a large force of troops having just returned from a three days' successful encounter with the dacoits, or "pirates," as styled by the French. The pirates had crossed the river, and had been heard firing on the opposite side. The hills now receded from the river, and in every direction over the flat valley fires and smoke came from the burning of the villages, or were signals by the pirates.

I re-embarked, and had a sail hoisted on the sampan, the ropes of which were merely the bark of some creeper or liane. We moored for the night at a military post, called Les Mines de Cuvie; but warned by two sampans bringing up ammunition that pirates were about, we anchored in the middle, and passed an undisturbed night.

After passing the *massif* of Mount Bavi on the right, the delta of Tonquin may be said to commence. Chinese pagodas, and occasionally brick buildings, were visible amid the numerous villages. The junction of the Black and Red rivers is a very tame piece of scenery. The banks are low, flat, and treeless, and the water thick, and but with little current.

Vietri is a large military post where the great Clear River joins the Red River. Here again was bustle and excitement, as a large body of troops were starting to-morrow in search of some more marauders.

I continued my slow and monotonous journey in the sampan, with the boatmen very cross at having to go on during the night, and the Annamite sergeant and myself having to spend the night in urging them on. Enlivened by one or two false alarms of pirates, we reached Hanoi, the capital of Tonquin, and there was a charm, though a sense of awkwardness, in approaching again a place boasting anything of Western civilisation.

At Hanoi I may be said to have finished my journey. The town has no great interest to a traveller; its development has been entirely owing to the large official population of Frenchmen, and these are making it attractive, but its situation in the centre of the delta does not permit of its ever being very charming. A daily steamer took me to Kaiphong, which is the port and seat of commerce of Tonquin.

There are fine warehouses, but nothing in them. The Chinese have left the place. Piracy flourishes within a mile or two of the town, and prevents the natives, through fear, from cultivating the soil. Undoubtedly, however, the delta is rich in soil and in minerals. There is a seam of coal a little way to the north, at Hongay, 169 feet thick. Unfortunately the French home policy has retarded the development of the country.

I visited, in a coasting steamer, the different magnificent harbours on the Annam coast. Rolling green hills, that look as if they would afford excellent pasturage, embosom fertile valleys. The coast, like the delta, is healthy, a contrast to the fever-stricken mountains of the interior. I landed at the charming town of Saigon, having everywhere met with the greatest kindness from the French in their new possession.

It is to be regretted that the French at home don't give a free hand to those in Tonquin to develop the country, in place of trying to keep it as a close market for their own goods. Cochin China was prosperous because of free trade, now it suffers from that advantage being taken away. Tonquin has never had the chance, and with the slow influx of capital, the resources of the delta remain as they were before the arrival of the French. Every kind of restriction is placed on the introduction of foreign capital, to the detriment of the country; whilst the Government monopoly of opium-growing, and the heavy taxes levied on the people, combine to drive them to piracy. It must be said that the French in the possession would gladly see all this altered; the fault rests on the selfishness of those at home.

DISCUSSION.

Sir STEUART BAYLEY, K.C.S.I., said every one present must have been highly gratified at this very interesting paper, giving an account of such a long and adventurous journey, which was so fully illustrated by beautiful photographs. Possibly the most interesting part of the paper to many, and that on which there would be most room for difference of opinion, was that which dealt with the frontier question—as to making the Mekong our boundary, or going beyond it—but that was one which could not be discussed in that Society. He would only remind the Society that the rights and interests of Siam had to be considered. Quite apart from political questions, there were many other points connected with the country on which he was sure those present would be glad to get any further information from those experts who were present, the principal one being, perhaps, the question of trade routes. Lord Lamington had told them, as appeared obvious from the map, that trade from Tonquin could not be expected to go by the Black River to Chiengmai, in competition with the easier routes he had named; but there were many other trade questions, which would be of interest to everybody. Not long ago the proposal for a railway, which was to run through Siam to Yunnan, from the Gulf of Siam, was brought forward, and a proposition was made which reminded one of the description of charity, in which A and B met together, and decided that C should be relieved at the expense of D. In this case the projectors and chambers of commerce decided that the trade between China and this country would be relieved by having a railway to Yunnan, the guarantee for which should be given by the Indian taxpayer, but the Indian Government did not see it in that light, and seemed to consider that if the money of Indian taxpayers was to be spent on a railway, it would be better to have it in a country over which they had some control. The question was still very much interesting the public what would be the best line of railway through this country, but whatever line was taken it must in some way strike the Northern Shan States. One of the difficulties attending the study of Siamese geography was the extraordinary difference in the spelling of names. At one time Chiengmai used to be Zimme. In the south the former syllable was spelt Chieng, but in other maps made by Indian surveyors it was Kieng. Probably it was owing to a difference of pronunciation, the Siamese pronouncing it soft and the Shan States hard. Similarly with regard to the river systems, those in the south of Siam seemed to be called Me, as Me-Kong, but higher up they seemed to be called Nan. He hoped someone with personal knowledge of Siam would throw light on these points.

Sir CHARLES CROSTHWAITE, K.C.S.I., had also listened with very great interest to Lord Lamington's paper. It was very gratifying to those who had to deal with these questions on the spot, from an official point of view, to find men in Lord Lamington's position coming out and visiting these countries, and giving their views on them from an entirely independent standpoint. He hoped many others would follow his example, and visit the great countries of Burma and the Shan States which had fallen under our administration. The question of boundaries must be left to those who

were responsible for dealing with it; but there was nothing of an unpleasant or hostile nature at present arising, nor need there be. It was natural, when we were occupied in annexing Upper Burma, that there should be some little disturbance on the frontiers of the old Burma Empire, and that encroachments should take place, which would now be settled in an amicable spirit. It was a matter of comparatively little importance whether these countries fell under our power or under the friendly power of Siam. The real question was who was to get the trade with them, and how we could make the most of them so as to find fresh markets for our goods, and also employment for those superflous articles of the present day, our boys. This was a question of a great deal of importance, on which a great deal had been written. Everybody who had looked into it knew the route so ably advocated by Mr. Colquhoun and Mr. Holt-Hallett for making a railway from Maulmain, up the valley of the Salween, and through Siamese territory to the Shan States, a line which they hoped to connect with another railway coming from Bangkok. Although at present the question of the route was still open, and could not be decided, because sufficient information had not yet been obtained, he ventured to think the true course would be for us to remain, as far as possible, within our own territories, and, therefore, to start off from a point on the Mandalay Railway, and take a course up to the north-east and through the Shan States, and in that way touch the border of Yunnan; from thence, perhaps, deseending again, and dealing with the countries through which Lord Lamington had passed. At present the surveys were incomplete. He hoped that those interested in the trade of England would keep public attention to this point. We had annexed the country of Burma, which of itself was of great value, but its real importance lay in the fact that it might become the high road of our trade with China, and by that means, with a port like Rangoon and a railway running up to the Chinese frontier, we could get command of a new field for English commerce. If those who had the leisure, opportunity, and power of effecting such enterprises would go into these countries, and bring their influence to bear on questions of this kind, much good would be done.

The CHAIRMAN then invited Mr. Ridley, the engineer of the chief line from Bangkok to Chieng-mai, and on the Chinese frontier, to give the results of his observation.

Mr. RIDLEY said his stay in Siam was of very short duration, and, owing to the dryness of the season the steamer by which he travelled stuck in the river, and he was not able to learn very much. Altogether, there were eighteen engineers engaged on projecting the various railways shown on the map, which were intended to go up towards Luang-Prabang, but for some reason the Siamese Government had abandoned part of it. Possibly one or two of those gentlemen might be present, and if so, would be able to give more information than he could. The total length of the line from Bangkok to Chieng-sen was about 620 miles, from Sarraburrie to Khorat about 95 miles, and from Bangkok to Khorat 145 miles. The highest summit which had to be passed was just beyond Zimme, and the level of the line there would be 3,173 feet above sea level. The height of the range was much higher than that, and the railway, when made, would have to go through a tunnel about half the length of the Mont Cenis, or nearly four and a half miles. The whole of the time the engineers were there, the reports they sent home fully confirmed what had been said in the paper as to the very peaceable disposition and amiability of the Siamese. At first they were rather shy, but after a short time they found that the engineers were honestly engaged, not intending to rob them, and they had no trouble whatever. The natives used to come into the camp and bring them supplies with great readiness. His own impression was, that if the projected line were made, it would be very important to connect it with Maulmain and British Burma, but it was not easy to design a railway across a country like this, where the jungle was so dense, and, in some places, grew from 15 to 25 feet high, so that an engineer found it very difficult to select a route. A short time ago the Siamese Government had made a contract for the construction of part of the main line from Bangkok to Aynthia, and for the branch line to Khorat, and the first sod would probably be cut in the course of a few months.

General MICHAEL, C.S.I., said:—I have really very little to say beyond expressing pleasure at hearing the very interesting paper which Lord Lamington has read. I should not have ventured to speak at all but for one sentence in it, which appeals directly to my feelings as an old forest officer. It is this, "We saw a certain amount of teak, but this, wherever it can be worked to a profit, is fast disappearing before the axe of the Burmese forester, and there are no attempts at replanting." I know too well what this means. Cruel waste and rapid destruction of old and young trees indiscriminately. Lord Lamington's graphic description of his river journey recalls vividly to my recollection an expedition which I made, more than 40 years ago, up one of the southern Burmese rivers, shortly before the war of 1851, which gave us Rangoon and British Burma. I then saw the waste and destruction caused by the uncontrolled Burmese forester. I had been sent by the Madras Government to see whether I could pick up hints from the Burmese system of working which might be turned to good account in the experimental conservancy work on which I was then engaged in the Anamully hills. If England or the Government of India are in a

position to offer advice to Siam, the importance of preserving their forests should be advocated. The Siamese have an example close at hand, in the effects of good forest administration in British Burma and throughout India.

The CHAIRMAN, in proposing a vote of thanks to Lord Lamington, said he should like to refer to what had fallen from General Michael, who said he hoped that the question of re-foresting the lands of Siam would be brought forward, and that British officers should influence that country in the direction of re-foresting. It was a great satisfaction to him to be able to say that the enlightened ruler of Siam was establishing a forest department for the very purpose of doing what General Michael suggested. He felt a strong personal interest in Siam and its government, and without touching on any political questions, he must say he was very glad to see this young English statesman so alive to the obligations and responsibilities which, more than half a century ago, England took upon herself with regard to this kingdom of Siam. After Bowring's treaty with Siam, we had been in constant communication on both political and trading matters with the various rulers of the country, and whilst we had reaped considerable advantages from that treaty, we had not in any way paid for it by any obligations or anxieties of our own. If the question of boundary was to be settled by France and ourselves, he trusted the obligation and duty we owed to Siam would not be lost sight of. In 1875, when conducting negotiations in Siam, he was assured by the then representative of France, and subsequently by a dispatch from the French Government, that French influence did not extend in the direction in which it was now going, and that her area of intervention was entirely confined to the south-east and Lake Cambodia; and, therefore, whilst certain subjects with reference to authority in the Shan States were raised, at that time France had in no way interfered. The present ruler of Siam, during the 20 years that he had been on the throne, had acted in such a way as to demand the sympathy and support of Englishmen. He was the first to declare that slavery should cease out of his land; and every opportunity had been taken, and every effort made, considering the enormous difficulties he had to deal with, to stamp it out throughout his dominions. With reference to the occupation of the land, and the way in which it was held, he had studied our Indian system, and instead of the oppression under which the lands were held at that time, had introduced a system by which the ryot and the farmer could enjoy a fair amount of his toil. His object, as he himself told him in 1875, was to have a free people on a free soil. When he ascended the throne, posts of communication and post-offices were unknown; but these were powerful influences in developing enlightenment and civilisation, and they were now fairly distributed. He had also introduced the telegraph, to bring the various centres in connection with the capital. He had also done much with reference to the sanitation of the towns, although there was a good deal yet to be done; and also with reference to various old customs; the chiefs having armies and retainers of their own he had swept away, and there was but one army and one revenue. At times, every chief took toll, and even in Bangkok, in 1875, there were taxes for the first king and taxes for the second king, and for various high officials. All that was swept away, and with it the corruption and oppression under the old system. He had done much to purify the courts of justice, and make them worthy of respect, and all this in the face of enormous difficulties, one of the greatest being that arising from the very treaty obligations he had with this country with regard to the consular powers. He hoped, when the time came, there would be sufficient public opinion in this country to justify a change being made which would restore Siam to the independence she had lost by those treaties. He hoped that when the settlement of the boundary took place care would be taken that not one single acre of territory to which Siam was justly entitled should be sacrificed for any political reason, and that we should do all we could to create an independent Siam, and offer to it and its Government our most hearty support and sympathy. If this were done, he believed it would be of enormous value to the best interests of England.

The vote of thanks having been carried unanimously,

Lord LAMINGTON, in reply, said undoubtedly the King of Siam was doing an immense amount of good work for his country, and was trying to bring it more and more into a liue with the ordinary ideas of Western civilisation. Of course, he had great difficulties to cope with; first of all, whilst at Bangkok and the surrounding districts he was able to exert absolute authority, owing to the want of communication, it was very difficult indeed for him to enforce those regulations in the more distant parts of the country. That was one reason why it was so desirable that Siam should have communications opened up by means of railways. From what he saw of the country, he believed that a railway would eventually pay. It was true there was a great want of population, but a railway would create population. It created wants, and led to the land being brought under cultivation, and when that was done towns would spring up. From Bangkok to Chieng-Mai it was now a three weeks' journey for passengers; for goods it took about five weeks, the distance being about 500 miles, yet Chieng-Mai was a very flourishing place with a good market and a certain amount of wealth, and if there were a railway the journey could be done in 24 hours. The difference in cost of a ton of goods in Bangkok and Chieng-Mai was something enormous. The railway would certainly be made some day, and it might also be desirable for British interests to have a separate railway in British terri-

tory, but there was ample room for both, and he believed that each would help the other. Rivalry in trade produced trade. Some people had an idea that when one country got good trade the adjoining country suffered, but he did not believe in that notion at all, and although we might have our own line from Burma into the Shan States, he hoped the King of Siam would have another running to Chieng-mai, eventually perhaps joining our line at Chieng-sen. With regard to the difficulty about spelling names, every person who made a map spelt the name differently. A European in Siam would spell a name as the Siamese pronounced it, another in Laos would spell it as it was pronounced there, and some-one in Burma would write the name in a different way, there being slight differences of pronunciation in each case. The particular instance of Chieng-mai being called Zimme arose arose from the Burmese being incapable of pronouncing the word Chieng-mai, and he had even seen a map made by Indian surveyors in which Chieng-mai was put in one place, and Zimme a few miles off. With regard to the frontiers, there was room for all parties in Indo-China, and he thought the English and Siamese Governments deserved great praise for putting the frontiers in order. There only remained a very small portion which was practically still unsettled. Otherwise the whole boundaries were agreed upon. He was perfectly well all the time he was travelling, but had an attack of fever after he returned home. It appeared to be generally the case that Europeans whilst employed in the jungle were perfectly well, but when they got back either to their temporary home or to this country fever was certain to develop.

Mr. Holt S. Hallett commuicated the following remarks on Lord Lamington's paper:—The information obtained by Lord Lamington during his journeys in Indo-China should prove of intense interest to our commercial and mercantile communities, and should be closely studied, weighed, and considered by the officials in charge of our foreign and Indian affairs. Such action is all the more advisable and necessary in face of the lamentable political fiasco that has recently occurred, much to the indignation and vexation of our merchants and manufacturers on the West Coast of Africa, where a vast and rapidly increasing British market has been snatched from us, and finally annexed by the French. Matters promise to follow exactly the same course in Indo-China, and with no excuse for the astonishing ignorance and apathy displayed by those controlling our foreign and Indian affairs. By the treaty of 1769 with the King of Burma, it was stipulated that the King of Burma "should re-open the golden road to China." This proves how much attention was paid to the subject of increasing our trade relations with China, even at that early date. In 1795, a British envoy was sent to Burma, with the same object in view. Since our acquisition of the Burmese coast provinces of Arakan and Tenasserim, in 1826, our merchants have been vigorously improving their trade relations with Indo-China, and looking eagerly forward to the time when the means of interior communication would be so far improved as to enable them to lay down our merchandise, not only in Indo-China but in South-Western China at a price which would ensure us millions of customers, who, without cheapened means of communication, were precluded, by their comparative poverty and the great cost of carriage, from becoming extensive purchasers of our goods. Even with the present cost of carriage we have so expanded our trade that thousands of our fellow subjects have for many years been employed throughout Siam and its protected States conveying our goods, and the great market covered by the Siamese dominions is practically, and nearly exclusively, a British market. To understand the threatened action of the French in the half of the Siamese dominions that lies in the valley of the Mekong, we must remember that the policy of creating a great eastern empire for France, that was to fully compensate for the loss of their Indian Empire, was fully set forth by Admiral de la Grandiere, the first Governor of French Cochin China, after the annexation of three provinces from Annam in 1862. As this policy has been consistently carried out step by step, as occasion and means allowed, by the French ever since it was first set forth, and as its continuance has been urged and openly avowed by every French official that has set foot in Cochin-China, it will be well to look it plainly in the face, and consider how far it conflicts with British interests in China and Indo-China. Admiral de la Grandiere's policy was the annexation of the whole of the Annamite dominions (including Cochin-China, Annam, and Tonquin), Cambodia, the Siamese provinces and protected states in the basin of the Mekong, the Burmese Shan States in the basin of the same river, and the southern provinces of China, as opportunity arose through the frequent insurrections in that part of the Chinese Empire. All of these places formed extensive, and nearly exclusive markets for British, British Indian, and British colonial goods, and all of these markets, in which French goods hardly made an appearance, would be closed to all but French manufactures as soon as they had passed into French hands. Since 1862, the French have so far carried out the admiral's policy as to incorporate Cochin-China, Annam, Tonquin, and Cambodia in their dominions, and have for many years been employing officials, in the guise of scientific travellers, to spy out the Burmese and Siamese possessions in the valley of the Mekong, with the view of eventually incorporating them in French Indo-China. China has, as yet, proved too hard a nut for them to crack; and the annexation of Tonquin has proved a costly and not very satisfactory affair. French attention is now evidently turned to the Burmese and Siamese possessions in the basin of the Mekong. That early action may be expected is evident from M. Ribot, the French Foreign Minister's

speech last October, and from the appointment of M. Pavie, late French Consul at Luang-Prabang, as Consul-General at Bangkok, and M. Lanessan, as Governor-General of French Indo-China. If we allow the portions of the Burmese Shan States of Kiang Hung and Kiang Tung, which lie the east of the Mekong, to fall into the hands of the French, by not asserting our supremacy over them, we block the best route for railway connection between Burma, Siam, and China, and enable our French rivals from Tonquin to replace our goods in south-western China and Shan States by French manufactures. The "Sibsong Pana," which, according to Lord Lamington, is "held to be the richest and most fertile region in Northern Indo-China," implies "twelve provinces," and is applied by the Shans to the twelve provinces of Kiang Hung, three of which lie to the west of the Mekong, and nine to the east of that river. I need hardly draw attention to the recent acts of war perpetrated by Siam upon the territory of our vassals, during which they have annexed districts of our protected State of Kiang Tung (Kyaington), namely Muang Fang, Muang Ngam (Meungnyam), Kiang Hven, and Kiang Kheng (Chieng Kheing), and destroyed the Viang Ké group of villages. By allowing the Siamese to keep these provinces of Kiang Tung, and preventing the chief of that State, who is now our vassal, from reconquering them from Siam, we are not only wronging him, but are allowing the Siamese to keep territory which, in their hands, may any day be lost to us as a market by being annexed by the French. The Siamese should be forced to retire from these provinces of Kiang Tung, which they could not have conquered or kept had it not been for the rebellions recently raging in the Burmese Shan States, and the consequent disturbed and weakened condition of the Shans. Even though some of these annexations like that of Kiang Hsen and Muang Fang occurred as early as 1881, these provinces of Kiang Tung were merely held by force, and no peace had been signed by the Chief of Kiang Tung giving up his claims to them. He still claims them, they are his by right, they form part and parcel of the Burmese dominions, and Siam has no right whatever to them. The policy of annexing the territory of its neighbours is an insane one for Siam to pursue. It sets a very bad example to the French, which they will doubtless be only too glad to follow at the expense of Siam.

The blocks of plans illustrating Lord Lamington's route have been kindly lent by the Royal Geographical Society.

FOREIGN AND COLONIAL SECTION.

February 16, 1892; The Hon. JOHN X. MERRIMAN, M.L.A., in the chair.

The paper read was "The Forthcoming Exhibition at Kimberley," by LEWIS ATKINSON. The paper and report of the discussion will be printed in the next number of the *Journal*.

TENTH ORDINARY MEETING.

Wednesday, February 17, 1892; General Sir GEORGE CHESNEY, K.C.B., C.S.I., C.I.E., in the chair.

The following candidates were proposed for election as members of the Society:—

Ellis, Walter L. J., 30, St. John's-wood-road, N.W.
Herschel, Alexander Stewart, M.A., D.C.L., F.R.S., F.R.A.S., Observatory-house, Slough, Bucks.
Parsons, Hon. Richard Clere, Oak Lea, Wimbledon-park, Surrey.
Sturge, Edward Brockway, 20, The Waldrons, Croydon, Surrey.
Wollaston, Arthur N., C.I.E., India-office, S.W., and Glen-hill, Walmer, Kent.

The following candidates were balloted for and duly elected members of the Society:—

Goodman, Prof. John, The Yorkshire College, Leeds.
Handcock, Henry W., Lanorna, Blyth-road, Bromley, Kent.

The paper read was—

THE PAMIRS AND NEIGHBOURING REGIONS.

By CAPTAIN F. E. YOUNGHUSBAND, C.I.E.

Looking from the plains of Northern India one sees to the north a lofty barrier of snow-capped mountains which enclose the Punjab like a wall. Yet these ranges visible from the plain are only the first of a succession of similar ridges which rise tier upon tier till the main axis of the Himalayan system—the watershed which divides the rivers of India from those of Central Asia, and which roughly forms the boundary of the territories under the influence of the Government of India—is reached.

Up to this point the country is fairly well known, and many writers have told how, passing over the first range from the plains, the lovely vale of Kashmir is reached, from which again rise forest-clad mountains with snowy summits; and how, on the other side of these, the traveller finds himself among bare sterile mountains almost entirely devoid of vegetation, which, increasing in height as one penetrates inland, finally culminate in peaks of 25,000, 26,000, and even 28,000 feet in height. So far our knowledge of the country is considerable, though even here there is much

to learn, especially about the vast seas of ice with which the valleys near the highest range are filled. But beyond that point we are yet very ignorant. Light, however, is gradually being thrown upon it, and now I would add one more ray to those which have been sent forth by the bold and hardy travellers who have preceded me in the gradual exploration of the unknown.

The portion of the mountain barrier on the northern frontier of India which I wish now more particularly to describe is that round the meeting point of the Hindu Kush and Karakoram or Mustagh ranges—the apex of Central Asia as it were, where waters divide north and south, and east and west, and which, too, is the cradle of the Aryan race, and the spot whence sprung many of the chief languages of the globe. To the north of this is the region of the Pamirs, the Bam-i-dunya—the Roof of the World—round which the three great empires of India, China, and Russia touch each other. Intensely interesting this region is to study, to talk over, and to read about, and yet the traveller who visits the spot sees little to arouse enthusiasm in him. In place of the great, lofty peaks which he would have seen on his way thither, from whichever side he approached the Roof of the World, whether from the east by the Tagarma peaks (25,000 feet high), or from the west by the lofty mountain summits overhanging Shighnan, or from the south by the great peaks—nearly 26,000 feet—round Gilgit and Hunza, or from the north by Peak Kaufmann (22,000 feet); in place of these, when one comes to the Pamirs proper, one sees mountains rising for a very few thousand feet above the valley bottoms, and often, especially at the eastern end of the Great and Alichur Pamirs, the mountains have dwindled down to mere low, rounded hills. Nor are the valleys more striking than the mountains. They are not fine gorges hemmed in by lofty, precipitous cliffs like one sees in Hunza, but open, level plains, four or five miles in width, bounded by gentle gravel slopes leading up to the mountain summits. They are not finely wooded and picturesque like those in Kashmir and Ferghana, but are entirely devoid of trees and even shrubs. And, lastly, they are not richly cultivated or dotted with thriving hamlets and villages as one sees in parts of the Himalayas, but for the most part covered with coarse scrub, with patches of good grass at intervals only, and inhabited by pastoral nomadic people living in tents.

The region of the Pamirs, in fact, consists of a succession of long broad open valleys, running approximately parallel to each other in a general direction from north-east to south-west, and separated by low ranges of mountains, rising, as I have said, to no considerable height above the valley bottoms.

The climate of this inhospitable country is one of great severity. The very lowest point of the Pamirs is 10,300 feet above sea-level, and their usual average is from 13,000 to 14,000 feet, and naturally the cold at such great altitudes must be intense. Of the winter I have had no experience, and can only judge of what it must be from what I have felt in the late autumn, at the end of October and the beginning of November, when I have seen the thermometer 18° below zero (50° of frost). The Kirghiz tell me that the snow then usually lies about knee-deep, but seldom more than that. They remain on these high valleys all through the winter, while their flocks and herds find what they can to eat, grubbing amongst the snow. Spring hardly occurs at all. The hardy French traveller, Bonvalot, and his companions, crossing the region in March, suffered most intensely from the cold; and Colonel Gordon and the members of the Forsyth Mission, who visited it in April and May, found the country still very wintry in appearance. By the end of May, however, the snow seems to melt, and soon after summer may be said to commence, though even during that season the nights are still very chilly. The earliest date on which I have been on the Pamirs is the beginning of August, and then the water in the basin of my tent was frozen at night. Snowfalls occurred by the end of that month, and at the end of September the thermometer had reached as low as zero, Fahr.

But though the climate is severe now, it must at one time have been still more so, for one sees constantly on them and especially on the Alichur Pamir, signs of glaciers even in the valley bottoms. At the present time there are no regular glaciers, or rather only very small ones near the higher peaks. But formerly I should almost imagine the Pamir valleys to have been filled up with seas of ice, and the impression which one is given on looking at the hills and valleys of this region is that the mountains must have formerly been of a considerably greater height than they are at present, and that in course of time they have crumbled up, decomposed, and, as it were, melted away, their remains falling into the valleys and choking and gradually filling

them up; while the climate was too severe for there to be a sufficient rainfall to wash this *débris* away. Even now, if the climate were to become milder, and the rainfall consequently greater, the Pamirs would exist no longer, but be scoured out into deep valleys, such as exist all round this elevated region. For one remarks in every instance of a Pamir that at its lower extremity where the climate becomes milder, the summer longer, and rain more frequent, the gravel of the broad level Pamir valley is wasted away, and the river runs off through deep gorges. The Great and Little Pamirs, for instance, end up in the deep-set valley of Wakhan, the Alichur Pamir in the defiles of Shighnan, and the Tagh-dum-bash Pamir among the narrow passages of Sarikol.

A point, too, which ought to be noticed about the mountain systems of the Pamir region is, that the watershed of the range connecting the mountain systems of the Himalaya and the Hindu-kush with the Tian-shan is not the main axis. The watershed across the Pamirs, which divides the river systems of eastern and western Asia, is a comparatively insignificant range, with peaks probably not more than about 20,000 feet high, and few even of that height. But east of these is the great wall of mountains which overhangs the plains of Kashgar, with peaks over 25,000 feet in height, a bold, clearly-defined line of mountains, which ought certainly to be considered the real axis of the connecting link between the mountain systems of northern and southern Asia. It often occurs, indeed, as in this instance, that the real axis has been cut through by streams running from a water-shed of inferior dimensions lying to one side; and map-makers who mark the watersheds more distinctly, and throw the really higher axes of the mountain system into the shade, often mislead the traveller, who expects to see high ridges where perhaps low ones only exist, and comes across vast mountains, when only low hills were looked for.

The most southerly of the Pamirs is the Tagh-dum-bash, and beyond that the country changes in a remarkable way. I had the good fortune, in 1889, to have the opportunity of exploring a hitherto unknown tract of land, lying between the last-named Pamir and the caravan road which leads from Kashmir to Yarkand. On our maps all the valleys on the south side of the great range of the Karakoram or Mustagh mountains in this part were shown as filled up with vast glaciers, but nothing was known as to the character of the northern slopes of these mountains beyond what I had seen of them when crossing the Mustagh Pass. In 1889, however, I found glaciers on both sides, all the valleys in fact, on the north as well as on the south side of this strip of two hundred miles, being filled up with great seas of ice. The sides of the valleys are steep and precipitous, and the mountain peaks rugged and enormously high, showing the greatest contrast between the Pamir country on the one hand and the undulating gravel plains and rounded mountains in the vicinity of the Karakoram Pass on the other. It struck me, indeed, that the great mass of peaks round Mount Godwin Austen, four of which are 26,000 feet high, and Mount Godwin Austen itself, over 28,000, must attract more than their proper share of the monsoon clouds coming up from India, the snowfall consequently being greater here than in the regions on either hand, and hence this vast accumulation of glaciers which are probably the most wonderful on the face of the earth.

Time does not permit me here to describe them in detail, but I hope that a few general remarks upon these marvellous creations of nature may prove of interest. Ascending the broad pebbly bed of any of the streams which run down from the northern slopes of the Mustagh mountains one sees in front what appear to be great heaps of gravel, from the foot of which issue a stream. On nearer approach, one finds that the heart of these gravel heaps is pure ice, and that this is the extremity of a glacier. Clambering up to the summit of one of these mounds, the traveller looks upward over a sea of needle-like pinnacles of ice, and amongst these sees long lines of rocky *débris*, the medial moraines of the glacier; while on either hand mountains of stupendous height rise in stern and solemn glory. These pinnacles or seracs of ice are of every fantastic shape and variety of colour, sometimes pure opaque white, sometimes dark green, and sometimes a delicate transparent blue. Amongst these may be seen fairy-like caves and grottoes of pure ice, with icicles twenty or thirty feet in length hanging from the ceilings or formed in a delicate fringe across the entrance, and into the walls of these lovely caves one can look as into a sheet of glass. Still ascending the glacier through mile upon mile of this beautiful ice scenery, the seracs become less sharp and distinct, and the moraines disappear, till at length the great snowfields at the head of the glacier are reached. Here all is white, pure and unblemished; and the bold intruder is deeply

and unforgetably impressed with the noble sublimity of the mountains towering round on every hand, and moved by his audacity in daring to intrude into regions ruled by nature in such stern and stately grandeur. He feels, too, what tremendous forces must be so constantly and continuously at work beneath the calm and placid surface; for while at first sight all seems still and unchangeable, a glance around shows the glaciers rent into great chasms with perpendicular walls of ice, perhaps hundreds of feet deep, into which, if a stone is dropped, it bounds from side to side, and the echoes are heard coming up from the very heart of the glacier. And then a little observation shows that these vast seas of ice, motionless and immovable as they seem, are year by year forcing their way down the valleys, carrying on their icy bosoms the fragments and craigs of rock which have been broken off from the mountains by the nipping fingers of the frost. Great cliffs, too, are met with, worn away and ground by the glacier forced against them; and I have seen a whole cliff of limestone polished and smoothed by the glacier almost as well as small fragments of rock are by the hand of man. With evidences of such mighty forces as this before him, the lonely traveller cannot but feel overwhelmed and awed as he looks on this marvellous handiwork of nature, and sympathise with the superstitious hill men who regard these mountains with such reverence and respect.

Many interesting phenomena, too, may be witnessed in these mountains. I have looked on a mountain peak, and then, a few moments later, seen it gradually disappear before my eyes, almost as if it had vanished away; and it was only by a closer observation that I could make out that it had been overshadowed by an imperceptible snowstorm. The snow, indeed, in these mountains was often very fine, and almost like dust; and a very beautiful effect is, that it nearly always falls in perfect little hexagonal flakes, like little stars of lace-work, each one quite distinct, and remaining intact until it reaches the ground; then, as it has fallen, the snow of course remains white on the surface, but, digging into it, it appears of a beautiful delicate pale blue colour. Another effect of the snow is seen at the mountain tops, when the peaks seem to be fading away and vanishing off like clouds of whitened smoke—a beautiful effect, produced by the high wind blowing away the fine dust-iike snow at the summits. Again, another almost similar phenomenon on the mountain tops is that of long, level clouds, like streamers, flowing away from the peaks. The moisture-ladened air from the plains of India has been condensed on the icy mountain summits, and the wind has blown the mist away in a long thin streamer. Yet one other curious effect I have noticed amongst these mountains is that, after a snowfall, the air has been seen to sparkle and glisten, as if filled with glittering particles of snow lit up by sunlight, and yet the sky may be quite clear, and nothing apparently falling; and I was told that it is considered the presage of great cold to come.

Such is a brief description of only a few of the wonders of this region of peaks and glaciers, of snow and ice, and rocks and precipices where, it is needless to say, no inhabitants are to be found, and where few, indeed, even of the hardy hillmen of the Himalayas, have ever penetrated.

Streams issuing from these glaciers run into a river flowing for some distance parallel with the main range, and eventually joining the upper water of the Yarkand river. This river I had first discovered in 1887 when I crossed it on my way to the Mustagh Pass. I then knew neither exactly where it came from, nor where it went to, but in 1889 I followed it up for some distance towards its source, which I found to be amongst the glaciers east of the Mustagh Pass. Having found out whence it came, I was naturally interested in finding out whither it went, and following it down found it to flow, after a course of 150 miles, into the Jarkand river, and it was near the junction of these two rivers, and also at other points along the banks of the latter river, that I found the remains of human habitations, and signs of cultivation. The country, indeed, which is called Raskam by the Kirghiz, was formerly populated until the raids by the Kanjuti robbers of Hunza forced the inhabitants to leave their homes. I am told, too, that in those days merchants used to trade across the mountains into Baltistan and Kashmir, but this has lately been prevented, not only through fear of raiders, but also on account of the accumulation of ice upon the passes. Smelting furnaces, too, and fragments of smelted ore were noticed in the place, and there is little doubt that minerals are to be found in these mountains, but there are no indications or traditions that they are in sufficient quantities to be worthy of much remark.

It is time now that I should say something regarding the peoples who inhabit these mountainous regions beyond our frontier, and tell

you of the hardy Kirghiz of the Pamirs, of those interesting people the Chinese, our friendly neighbours beyond the border, and, lastly, of the bold robber tribe, the Kanjutis, who have played so important a part in the regions I am describing. The Pamirs are scantily populated by various branches of the great nomadic tribe, the Kirghiz, who inhabit nearly all the hill country in the western end of Kashgaria, who formerly peopled the country of Raskam in the valley of the Upper Yarkand river, and who have even penetrated to, and to this day live, in a spot so remote from the original home of their race in the steppes of Turkestan as Shahidula. They are a rough hardy race, not so tall nor so warlike as the tribes on our Pnnjab frontier, but well-built and strong, as they must necessarily be to withstand all the hardships of a winter on the bleak and barren Pamirs. The women especially are very robust in appearance, with ruddy rosy complexions, well set-off by the high white turbans they wear. They are not ornamental according to our ideas of beauty, but they may at least be called useful, for they appear to do all the work about the tent, milking the flocks and herds, making up the cheeses, manufacturing the felts, and doing all the thousand and one little things that are necessary in family life; while their husbands and brothers are, with the exception of the few who tend the flocks, idling their time and doing nothing. The men have indeed little in their character which one can admire. One admires an Afghan for his manliness, his love of fighting, and his patriotism; one even admires the Kanjuti raiders from Hunza for their boldness and enterprise; but the Kirghiz always appeared to me to have singularly little to attract one, for their whole character is too level and mild, having neither any particularly good or unusually bad traits to excite any large amount of interest in one for them.

My first acquaintance with these people—not with the actual inhabitants of the Pamirs, but with their brothers and cousins—was in 1887, in the hill tracts to the north-east of Kashgar. I was then travelling in the simple style in which some people think that explorers always, or, at any rate, should always travel. I had simply an Afghan interpreter and a Turki servant, while one pony carried all our stores and baggage. In this way we three used to ride forty or fifty miles a day, putting up for the night with the Kirghiz in their tents. The first evening of our ride we reached a small encampment where the only accommodation available for me was with four ladies. This rather embarassed me at first, for I am not very old now, and was younger still in those days. But my modesty was relieved when I found that three of the ladies were grandmothers, and the fourth a great-grandmother—their various children and children's children being away with the flocks on the higher summer pasturages. I was most hospitably entertained by them, felts were laid down in the tent for me, milk and curds were brought, and to crown everything, the great-grandmother insisted upon darning up some holes in my socks, which, as I had come all the way from Peking, were not in such good repair as one would usually like to see them. Every night in this way we used to put up with the Kirghiz in their tents. Usually they were hospitable enough, but on one occasion, when we arrived at a considerable encampment of from eighty to a hundred tents, we found them less friendly, and I noticed a dispute going on between my Afghan orderly and a crowd assembled round him. On asking him what the matter was, he told me that they were anxious to delay me, and talked even of robbing and, perhaps, murdering me. He, fortunately, kept his coolness and presence of mind though, asking them what was the use of delaying me, pointing out to them that I was travelling under Chinese protection, and asking them whether, on the whole, it would not be best to pass me on quietly to the next encampment rather than, by turning me back, to run the risk of annoyance from the Chinese. This they eventually saw. The matter ended peaceably, and I proceeded quietly on my way.

With the Kirghiz on the Pamirs, however, I had no such troubles; and on the three occasions on which I have been amongst them—in 1889, 1890, and 1891—I was always received with much cordiality. Felt tents were often erected for me in advance, sheep brought as presents, and all assistance given me; and, indeed, they seemed to have considerable respect for me, on account of my having actually visited Peking, the city of the great Khakan-i-Chin, the Emperor of China, an almost fabulous personage to them, and possessed, they imagine, of unbounded resources of wealth; the most potent ruler in the world, and the controller of armies, which could hurl destruction on all who opposed them. It is curious, indeed, with what superstition and reverence China is regarded by these Kirghiz and the inhabitants of Turkestan, none of whom have ever visited

the country, but who have to draw their own conclusions regarding it from their not very truthful conquerors, and from the fact that for centuries the Chinese have held their own in these remote regions, in spite of numerous attempts to overthrow their power. This last point, especially, is one which has great weight with all the people of Central Asia; and the prestige of the Chinese stands very high, from their having so determinedly and so frequently reasserted their authority with such unerring certainty.

I have interested myself much, too, both during my journey in 1887 from end to end of Chinese Turkestan, and again on my recent journeys in Kashgaria and the Pamirs, in examining the way in which the Chinese rule a conquered race, and comparing it with our own methods in India. I think the first impressions of an inquirer are rather unfavourable to the Chinese. They do little or nothing for the good of the country, they seldom improve the roads or construct canals, and education, except training a few natives as interpreters in Chinese, is almost entirely neglected; few or no officials speak the language of the country, and they are consequently very largely in the hands of their native interpreters; both the Chinese and native official accept bribes, and justice is often difficult to obtain; and, lastly, the punishments meted out are often very barbarous and cruel. Yet, in spite of all these very grave defects in their administration, I do not think that the Chinese are at all so unpopular as might be supposed. The natives have become accustomed to them, they do not look for or expect a highly civilised administration pure of every blemish, and they have had experience that, under Mahommedan rulers, they have been quite as corruptly, or even more corruptly governed; while what has, perhaps, most weight of all with them, is the fact that under the Chinese they are much less heavily taxed than they were under their own kings. Closer inquiry, too, shows that glaring instances of oppression are not really frequent, and, on the other hand, cases are not unknown where corruption has been very severely reprimanded. The cruel and barbarous punishments, too, occur but seldom. When a Chinese official does punish a man, he punishes him with extreme severity, and makes a lasting example of him; but, as far as I could ascertain, unless there was real necessity for doing so, the Chinese deal out punishment as rarely as possible.

The true secret, however, of the success of the Chinese, in addition to their prestige, is undoubtedly their perfect mastery of the art of impressing Orientals. We English in India are sometimes supposed to be too haughty and exclusive, but we might be considered low and familiar compared to the Chinese. It has its disadvantages, as they cannot possibly get in real touch with the people, but the Chinese system of extreme exclusiveness undoubtedly produces some good results. A Chinese district officer, even one of quite inferior rank, lives in a fine, large house, surrounded with high walls, and approached by massive gateways. He never appears in public except dressed in his neat silk official robes, and accompanied by an escort; and, most important point of all, he both pays the greatest respect to his superior and insists on it from those under him, while even his equals he always meets with dignity. A Chinese official, in fact, respects himself, and consequently is respected by others; and this is the grand secret why, with a very small force and at so great a distance from their capital, they are able to keep a conquered people in quiet and contented subjection.

Time does not permit me, however, to enter more fully into this subject, and before concluding this paper I must say a few words regarding the Kanjutis of Hunza, who have made such an impression upon all the country in the vicinity of the Pamirs. This tribe of robbers inhabit the deeply-cut valley which runs from the apex of Central Asia where the Hindu-Kush and Himalayan systems meet, and the watershed between eastern and western Asia joins that between northern and southern. They seem to be a remnant of the original Aryan stock which had overflowed from the first starting-point of their race to the north of the Hindu-Kush, and to have been left shut up in this secluded valley, while most of the other branches and off-shoots of the parent stock have been swept backwards and forwards by the tides of conquest, and drifted into far off and remote countries. Such a people cannot fail to excite one's curiosity, and the interest was naturally heightened in my case from having heard so much of their raids and bold forays in the countries through which I passed, before entering their secluded valleys. I found them to be small, well-built, hardy, determined, though not fierce-looking men, wearing long black curls, which gave them a very wild appearance. Perhaps the most remarkable feature about them is their capacity for en-

durance. They issue from their strongholds on their raiding expeditions, and cover often 200 miles of mountainous and uninhabited country, entirely on foot, and carry their own supplies for the whole distance on their backs; and I have known the cases of men carrying news of my movements to their chief in incredibly short spaces of time. Dressed in long cloaks of thick home-made woollen material, they sleep out in the open in the most intense cold, and yet live upon almost nothing. I remember on one occasion giving some Kanjutis who were accompanying me 2 lbs. of flour each, and was told that this was a regular feast for them for three days. Another characteristic of them is their avarice. Like most people they will not do anything for nothing, but they even seem to expect to get something for doing nothing. Money they did not appear to care about, as they scarcely appreciate its value, and when I gave a few of them some rupees they asked the Gurkhas of my escort what they were worth. The Gurkhas, with a cleverness for which they are not usually remarkable, would hold out a handful of tobacco and say, "Well, if you give me a rupee I will give you this much tobacco." Those that have been towards Gilgit and Kashmir are, of course, better aware of the true value of money, and all wish something and keep demanding presents for every little service rendered. The late Chief Safder-Ali-Khan was never tired of demanding things. I had given him and his Wazir a number of presents which should have been amply sufficient to satisfy them; but, unfortunately, I had given the Wazir a few pieces of soap wrapped in tinfoil paper. This seems to have excited the envy of the Chief, who had received none; for he promptly sent down two men, asking for some to give to his wives. Even when I had refused him, and told him that I had given him all that I ever intended to give, he used, day after day, to keep sending messages to me for every imaginable thing, down even to my tent and my mule trunks. The people seem to live mostly by agriculture, and are principally congregated in the lower part of the valley, where it opens out opposite Nagar. The produce of the fields, however, is scarcely sufficient for their wants, and they have to supplement it by living a great deal on apricots and other fruits, which are grown in considerable quantities. In the upper valleys they have flocks of sheep and goats, but they are very small, and not very numerous.

Such are the people whose chiefs have recently received at our hands the just punishment for their numerous misdeeds, and it is sincerely to be hoped that the peaceful cultivator in his village home near Gilgit, the indolent Kirghiz tending his flocks on the Pamir, and the enterprising trader wending his way across the mountains to Yarkand, may now enjoy that sense of security which this little robber tribe have denied them for centuries.

And here I must end this imperfect description of a region which has lately come so prominently into notice; a region replete with interest alike to the man of science, the student of languages, and the statesman; and the point at which the territories of the two great European rivals—or may I not say allies?—in the civilisation of Asia most nearly approach each other.

DISCUSSION.

The CHAIRMAN said they were all much indebted to Captain Younghusband for his very valuable paper. Everyone who had heard the very modest account he had given of what travellers in that region were exposed to, must entertain feelings of the highest admiration for those who underwent such hardships. What struck him most was the great stress laid on the very severe cold which had to be encountered, a matter which always appealed to the "gentlemen of England who lived at home at ease." They all sympathised with those who took part in Arctic expeditions, but what impressed them most was not the danger so much as the excessive hardships from cold which they had to endure. But except in the few cases where he had to leave his ship, the Arctic explorer had always the comfort of his cabin to resort to, and many Arctic travellers said that even in the bitterest weather they could manage to keep the ship itself almost uncomfortably warm. The travellers in the Pamirs had no cabin, and under no circumstances could he make his tent uncomfortably warm. Captain Younghusband's explorations had been of extreme value, not only to geographical science, but to the Government of India. The tracts he had explored were now assuming for the first time political significance, and, in dealing with political questions, the first essential was an intimate knowledge of the country in question. Having been lately connected with the Government of India, he could say how highly Capt. Younghusband's services were appreciated. It was said by a Latin author that poets were born, not made; and he thought the same would apply to adventurous travellers. Sir Roderick Murchison, the eminent geologist, began his career as an officer of dragoons, and Captain Younghusband did the same. He could hardly help saying, when he

saw the captain in evening dress, as if he thought of nothing but going to his club or into society, and then saw him mentally on one of his expeditions, with only two servants, with all their provisions carried on one pony, that he was a sort of geographical Dr. Jekyll and Mr. Hyde, appearing first in one character, and then in a totally different one. Mr. Andrew Lang, in one of his essays, spoke of explorers as representing the best type of English character, and remarked on the curious craving for fresh adventures, almost like that of a drunkard for alcohol, which always seized such travellers. When such a man got into what was termed a tight place, he would say, "Catch me here again," and sure enough you did catch him there again; and he had little doubt that, in a few months' time, Captain Younghusband would be on the war-path again. Until quite recently he belonged to the 1st Dragoon Guards, but the Government of India were so averse to losing his services that, when his regiment went home, they succeeded in breaking through the rules, in order that he might exchange into another regiment, and his services had now been secured permanently for the Indian army. He had no doubt that he would go on, and add many more to his list of achievements.

Lord CREMORNE said Captain Younghusband must often have found himself in an uncomfortable position, the nearest parallel to which that occurred to him being that of the adventurous Swedish professor, who not long ago traversed Greenland with a very small party. He had one advantage, however, in not having any doubtfully hospitable people to meet, the interior of Greenland being probably only uninhabited.

Sir HALLIDAY MACARTNEY, K.C.M.G.. said there were plenty of Englishmen who had the courage to lead a troop of horse, but to bear aloft—"Through snow and ice, a banner with this strange device, Excelsior!" required a very different and superior kind of courage. The country described was of great political interest at the present time, and it was astonishing that the heart of the oldest civilised continent should have remained until lately almost as unknown as the heart of Africa. The point of political equilibrium of Asia must be said to be changed many degrees further east; for while formerly they looked to Herat and Candahar as places of great importance, attention was now more directed to a point beyond the Mustagh Mountains, where the three great empires of China, Russia, and England met. He had listened with great pleasure to the testimony which had been given in favour of the Chinese, with whom he had so long been connected. He accompanied the Marquis Tsêng to St. Petersburg, after the region of Kuldja had been annexed by Russia, and lent him what assistance he could; and when the marquis succeeded in getting it restored to China, Lord Dufferin paid him the compliment of saying that he had accomplished what no man had ever done before, he had made Russia give back a province she had once annexed.

Mr. W. MARTIN WOOD said it was well to recollect that the pioneer in this modern exploration of high Asia was a member of the old Indian navy, the discoverer of the sources of the Oxus, and from that point, which was thought so striking at the time, one could measure how immensely our knowledge had been extended since. He thought the reader of the paper was a little hard on the Hunzas in describing them as brigands, and so on; for the photographs which had been shown seemed to offer some excuse for them, as it was difficult to see where they could find anything to live on, and they were no doubt driven to get their living how they could. Captain Younghusband had spoken of their receiving a just punishment from our troops, but that might be open to question, for they had never robbed our people or interfered with them. That was only an illustration of the extraordinary position in which we found ourselves in that region, where, as Captain Younghusband had said, our influence was constantly extending. It was our influence which had been pushed from within, not from without. Not much had been said about the Nagaris, but it was interesting to remark both on their similarity and contrast to the Hunzas, though they were of a similar race. They were superior to the Hunzas probably owing to their more fertile soil, and perhaps superior religion, or better customs with regard to other people. Speaking of English influence in high Asia, he would refer to the paper by Sir Alfred Lyall in the *Nineteenth Century*, in which he expressed the hope that England would not go on extending her boundaries, and thus increasing the responsibilities, which must weigh on the minds of reflective Englishmen.

Mr. OLIVER WILLIAMS, referring to the last sentence in the paper, said he hoped England and Russia might rather be allies than rivals. That time last year, he was travelling for some eight months through the Arctic seas, across a great part of Siberia, and came home through St. Petersburgh; and both the principal officials in Siberia and the ministers in the capital expressed their great desire for friendly intercourse and friendly exchange of commercial relations with England. They said that such a vast empire as Russia had ample work within its own territory which required developing in every way. There were vast regions which still required railways, canals, and other works which could only be carried out at great expense, and which must be assisted in such a country by the Government, who also had a great deal to do at present in connection with the famine. Russians were most desirous to show a friendly spirit to the English, and if we would only reciprocate it, great good would

result. His own experience with regard to the cold was, that while travelling night after night, with about 50° of frost, Réaumur, he did not feel the cold. One reason was that you were well wrapped up in furs and woollens, and, the other, that when the cold was so intense the air was always very calm.

The CHAIRMAN then moved a vote of thanks to Captain Younghusband, which was carried unanimously.

Captain YOUNGHUSBAND, in reply, said the kindness and appreciation which he received at home was a great encouragement to the traveller when wandering about in the wilds of Central Asia. He, like most travellers, had thought at times that he would never go in for that sort of thing any more; he had said so many times when crossing the desert on his way from Peking, on the glaciers, when exploring the northern frontier of Cashmir, and on the bleak and cold Pamirs; but when the traveller returned to his native country, and saw that an interest was taken in what he had done, and that people would still be interested in further journeys he might make, he felt his energies renewed, and was quite willing to undergo the hardships which must necessarily befall him, feeling that he was doing something for his government and his country.

Miscellaneous.

TRANS-SIBERIAN RAILWAY.

The *Board of Trade Journal* quotes the following from Dr. Meyners d'Estrey's article in the *Journal des Economistes* on the proposed railway across Siberia :—

"After the grand work of General Annenkoff in Central Asia, Russia has recently formed the project of constructing a still more gigantic railway. This is a line through Asia terminating on the Pacific Ocean and intended to connect the Chinese system with the European systems.

"The distances for the contemplated Trans-Siberian Grand Pacific are as follows :—From Tjoumens to Tomsk, 1,300 kilometres; from Tomsk to Irkutsk, 1,700 kilometres; from Irkutsk to Oustj-Strejelka, 1,300 kilometres; from Oustj-Strejelka to Oussouri, 1,600 kilometres; from Oussouri to Vladivostock, 500 kilometres. Total, 6,400 kilometres.

"This line will, therefore, exceed in length any of the Trans-American lines. In fact, that of Canada, opened in 1884, has only a length of 5,071 kilometres; the North Pacific, opened in 1883, 5,293 kilometres; the Central and the Union, opened in 1883, 5,260 kilometres; the Santa-Fé line, opened in 1881, 4,875 kilometres; the Atlantic and Pacific, 5,631 kilometres; the North Pacific, opened in 1883, 6,251 kilometres.

"The proposed line will meet few difficulties in connection with the level of the country; but the large rivers flowing from south to north, and which must be crossed by the line, will necessitate the construction of very expensive bridges. Thus, it appears, the opinion has been expressed that these rivers might be dealt with temporarily by means of boats. In winter the journeys would be made on the ice by means of movable rails. Such might be done for Lake Baikal, in order to avoid the great detour of 200 kilometres, which would have to be made by the line in order to pass to the south of this lake.

"The rivers to be crossed would be the Tobol at Tobolsk, the Irtysch at Omsk, the Ob to the east of Tomsk, the Tom at Tomsk, the Yenissei at Krasnojarsk and other arms of rivers of lesser importance.

"The system of crossing the river by means of ferry boats on which the carriages are placed is already employed at many places in Europe, among others near Hamburg; it works rapidly and does not cause any loss of time.

"The bridges which would have to be constructed over the rivers should be extremely substantial; they would have to resist the floating ice to be met with for a long period of the year in Siberia. This would, therefore, necessitate enormous expenditure.

"Further, there are other obstacles, such as the Yablonoi mountains, 1,150 metres above the level of the sea. But this altitude is really much less when it is seen that the passage through these mountains is situated 400 kilometres from the east coast of Lake Baikal, and that this lake itself is 409 metres above the sea-level.

"In the Amour valley the only question of difficulty will be that of the Oussouri. The eastern extremity of the line as far as the Pacific Ocean, near Vladivostock, will then be easily reached.

"It is difficult to form an estimate of the cost of these constructions. The Trans-Caspian line, which was inaugurated in 1888, cost about 32,000 roubles per verste (verste = ·633 of a mile), but it is most probable that the Grand Trans-Siberian will cost more, especially if it is desired to establish bridges across the rivers, which will sooner or later be inevitable in order to prevent delays and the continual expense of the transhipment of passengers and merchandise.

"The rivers may be crossed by ferry-boats in summer, and on the ice, when safe, in winter; but the ice drifts incessantly between these two seasons, and then the question of crossing becomes somewhat difficult of solution. This question has been put to General Annenkoff, and he counts on the construction of the line without bridges.

"This line has given rise to two proposals: one emanates from the Ministry of Public Works, the other is that of General Annenkoff. The Ministry of Public Works engages to construct the Trans-

Siberian within thirty years, and at a cost of 480,000,000 roubles; General Annenkoff only asks for four years and 300,000,000 roubles. It is probable that the system of the General will be accepted. Already the Ministerial Committee has given him its approval. He has also the support of the Ministries of War and Finance.

"The advantages presented by the Trans-Siberian are many. First for Russia, it will place St. Petersburg and Moscow in communication with its possessions on the Pacific Ocean, notably with the large military port of Vladivostock. It will permit Russia, in the event of a war with China, to rapidly muster an army on the frontiers of the Chinese Empire, and from a commercial point of view it will secure to Russia the situation as intermediary between Europe and the countries of the extreme East, such as China, Japan, and Corea. It will carry passengers and a large portion of the goods which, at present, take the sea-route in order to be forwarded from Europe to the extreme East and *vice-versâ*.

"The journey from Western Europe to Shanghai at present takes 44 days by the Suez route, and 34 days by the Trans-Canadian railway. It will be only 20 days by the Trans-Siberian.

"Along a large portion of the Trans-Siberian route, cultivation may be carried on over an area of land equivalent to the width of France from east to west, between the Vosges and the ocean. It will not be long before cultivation is commenced. When the Trans-Caspian was built, the country in which this railway of 1,000 kilometres was situated was only a desert. Now cotton is planted there with great success. Central Asia produces ten times more cotton than before the existence of the Trans-Caspian railway."

Correspondence.

BURNING OILS FOR LIGHTHOUSES AND LIGHTSHIPS.

As there was very little opportunity for discussion after the reading of Mr. E. Price Edwards's paper on "Burning Oils for Lighthouses and Lightships," I desire, with your permission, to correct a misapprehension that may probably arise from the remarks offered by Mr. Boverton Redwood, when he states that the definition of "inflammable liquid," in relation to lighthouse oil in the recent Inflammable Liquids Bill, was not objected to by the delegates of the Scotch oil companies.

The reason for this reference to the Scotch producers in his criticism of Mr. Edwards's paper is not quite apparent, and, to many who are not familiar with the history of petroleum legislation, it may be somewhat misleading.

It is well known that the Scotch producers, ever since the first Petroleum Bill of 1862, have on all occasions when the question of safety came under discussion in Parliament, or was the subject of investigation by Parliamentary committees, contended strongly for a high standard. But in the trade conferences of 1891, the question of the standard of safety was purposely never under discussion, as the general provisions of the Draft Bill submitted for their consideration were felt to be so onerous, that united trade action had become a necessity, in order to prevent serious, if not fatal, injury to the trade in mineral oils generally.

During 1891, however, the Scottish Mineral Oil Association, which comprises practically the whole of the oil producers of Scotland, issued a statement in regard to the Inflammable Liquids Bill, in which referance is specially made to the absurdity of lighthouse and other oils with flash points over 150° F. being brought within its scope, by the introduction into that Bill of quite a novel qualification, viz., specific gravity. That statement further says, "The subscribers desire to emphasise the fact that they have always maintained a standard of safety much above the requirements of any Act of Parliament; and that their mineral oils have, in consequence, stood the test of experience under all circumstances and in all climates, and have been practically free from accidents, either of conveyance, storage, or in use in lamps. To brand their manufactures, therefore, with the stigma that exceptional measures and precautions require to be adopted in their case would be manifestly unjust."

I may be permitted also to make some reference to the very remarkable statement which Mr. Redwood makes as to the result of experiments conducted by Sir Frederick Abel and himself, viz. :—"That substantially it was found that a lamp might be said to be in the safest condition when the space above the oil in the reservoir was filled with vapour." Now, if this is to be taken seriously, it is clear that Dr. James Young, the founder of the industry with Sir Lyon Playfair, and a host of other scientific men who have given special attention to this subject in England, in Germany, and in America, have been wrong in insisting that oils for domestic use should be high-test, with a minimum flash-point of 100° Fahr. That the more educated classes also, and public companies—such as railways, steamships, and lighthouse Boards—have all been erroneously seeking safety in high-test oils; and that the various Government departments, guided by Sir Frederick Abel himself, have been making a strange mistake in declining to use oil, even in a soldiers' camp, with a lower flash-point than 105° Abel test.

Mr. Redwood appeals from the few isolated experiments made by Mr. Edwards to the experiments made by the million every night, with lamps, in their own houses; but surely the sad scenes depicted from hospital experience by the late Mr. Charles Marvin, were enough to show that Mr. Edwards' experiments are oft repeated in the homes of the poor with

equally sensational, and too frequently with much more tragic results.

The unsafety of higher test oils, Mr. Redwood says, may arise from their volatilising slowly, and thus more liable to produce an explosive mixture. But the experiments of Mr. Edwards have frequently been confirmed by many other operators, that the temperature of oil in lamps rarely ever rises above 90° Fahr. after five or seven hours' burning, and usually it varies from 76° to 90° Fahr. High test oils, therefore, which give off no vapour under 100° Fahr. never reach the point in ordinary domestic lamps at which vapour can be produced, and, consequently, safety in their use is insured.

On the other hand, oils which begin to give off inflammable vapour at 76° to 90° Fahr. are exposed to such temperatures in the reservoirs of lamps, and are, therefore, maintained just at the point when volatilisation is least active; and it follows from this theory of Mr. Redwood's that 75° to 90° flashing oils are precisely the oils most dangerous to use under ordinary domestic conditions.

From an experience of 30 years with a great variety of lamps and oils, and having examined many cases of so-called lamp explosions, I should say that an explosion, in the true sense of the word, seldom, if ever, happens. What I have found is, that vapour, escaping from the lamp, flares up the chimney, or the vapour may take fire inside the lamps, and, under such circumstances, from the heat produced, the chimney breaks, or the reservoir may crack, or the soldered parts become disconnected; but, in the great majority of lamp accidents, the cause is either upsetting the lamp, or dropping it through carelessness, or from alarm when any flaring takes place. When a lamp is upset which contains oil that gives off vapour from 75° to 85° Fahr., the chances are, that the vapour and oil take fire, as they escape from the lamp, and the greater the volume of vapour present, the greater the risk.

The very exhaustive experiments conducted by Dr. W. Thörner in Germany, confirm our practical experience that the risk from any actual explosion in lamps is extremely small. He discharged an electric spark in the space above the oil in the lamp reservoir, and the result in nearly all the trials was merely a swishing noise, followed by the extinction of the flame, so that the energy of the slight explosion expended itself harmlessly up the wick tube. The explosions took place at temperatures varying from 76° to 84° Fahr., in the case of the ordinary commercial petroleum flashing at 74° to 80° Fahr. There were three explosions that were more violent than the others, and these were with oils flashing at 77° to 80° Fahr. The highter test, Water White and German Kaiser oil, did not produce an explosion till the oils reached 116° and 109° Fahr., and in these cases the explosion was slight.

We venture to think that practical experience fully justified Dr. Thörner in the opinion he expresses, that a petroleum which does not give off any explosive vapour at 100° Fahr. Abel test, may be used anywhere in Germany or in England with the most perfect safety.

William Love.

Obituary.

M. H. Blanchard.—Mr. Mark Henry Blanchard, the well-known terra-cotta manufacturer, died, in the 76th year of his age, on the 1st inst., at his residence, Bishop's Waltham, Hants, after a short illness. He was one of the earliest revivers of the use of terra-cotta, and, at the Great Exhibition in 1851, he obtained the prize medal for material and workmanship in terra-cotta. He carried out some of the most extensive works with this material throughout the country, more particularly those in the South Kensington Museum and the Gardens of the Royal Horticultural Society. Mr. Blanchard's premises were originally in the Blackfriars-road; but when the ground upon which they stood was required for public purposes, he removed to more extensive premises in Hampshire. As late as December of last year, a new invention of his for a fireproof staircase and flooring in terra-cotta was tested with, it is said, satisfactory results. Mr. Blanchard had been a member of the Society of Arts for nearly 30 years.

Sir James Caird, K.C.B., LL.D., F.R.S.—Sir James Caird, who died on Tuesday evening, 9th inst., although not a member of the Society of Arts, took great interest in the work of the Society. In December, 1857, he presided at a meeting, when a paper "On the Progress of the Agricultural Implement Trade" was read by Mr. S. Sidney; and he had promised to take the chair on April 18, when Sir William Wedderburn will read a paper before the Indian Section on the "Reorganisation of Agricultural Credit in India." During the 44 years between these two dates, he presided, on several occasions, at meetings devoted more particularly to the discussion of agricultural subjects. Full biographies of Sir James Caird have appeared in *The Times* and other papers, and it is not therefore necessary to do more here than set down the dates of the chief particulars of his life. He was the son of Mr. James Caird, of Stranraer, born in 1816, and educated at the High School and University of Edinburgh. Sir James Caird was M.P. for Dartmouth from 1857 to 1859, and for Stirling from 1859 to 1865. In 1860 he was appointed a Member of the Fishery Board, and, in 1863, became Chairman of the Royal Commission on the Sea Fisheries of the United Kingdom. He was appointed on the Famine Commission, to inquire into the circumstances of the great famine in India of 1876-7; C.B. in 1870, and K.C.B. in 1882; President of the Statistical Society, 1881-3; Member of the Royal Commission on Land Law (Ireland) Acts, 1885-7. He was also Senior Land Commissioner for England.

Sir James Caird was the author of several works on agriculture, which passed through numerous editions, and were translated into foreign languages.

General Notes.

CHICAGO EXHIBITION.—The *Austrian Gazette* publishes the nomination of Archduke Charles Louis, the Austrian Heir Apparent, as patron of the Austrian Section of the Chicago Exhibition. The Marquess Bacquehem, Austrian Minister of Commerce, is appointed President of the Austrian Commission, which further comprises five Vice-Presidents and seventy-five others as members of the Central Committee, and, finally, fifteen members of the Executive Committee. This is the strongest official body on record in this country connected with an International Exhibition, showing that Austria intends to be largely represented at Chicago.—*Standard.*

FRENCH SAVINGS BANKS IN 1891.—According to a report recently issued by the Minister of Commerce upon the situation of ordinary savings banks in France, it appears that the number of such banks existing in 1891 was 544, with branches to the number of 1,062. The number of new accounts opened during the year was 513,690, a falling off, as compared with the preceding year, of 12,175. The total number of accounts open at the end of the year was 5,936,825, and the amount of deposits during 1891 was 835,894,734 francs (£33,436,000). The total amount standing to the credit of depositors was 3,052,311,372 francs (£122,092,000). The *Monde Economique*, in reviewing the returns, calls attention to two remarkable points in connection with these statistics—the diminution of what may be termed active saving, and the augmentation of savings to which the word passive may be applied, by reason of the capitalisation of interest. The number of new accounts, which was only 513,690, amounted, in the previous year, to 534,865, whilst the total number of accounts open rose from 5,761,408 in 1890, to 5,936,825 in 1891. There is therefore a falling off in the savings, which points to a less prosperous condition of affairs. The deposits during the year have followed the same descending scale, and amounted to 835,000,000 francs in 1891, as compared with 869,000,000 in 1890. And yet the amount standing to the credit of the various depositors has risen from 2,911,000,000 francs in 1890, to 3,052,000,000 last year.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock :—

FEBRUARY 24.—ERNEST HART, "Ancient and Modern Art Pottery of Japan." Prof. WILLIAM ANDERSON, F.R.C.S., will preside.

MARCH 2.—Prof. VIVIAN B. LEWES, "Spontaneous Ignition of Coal, and its Prevention."

MARCH 9.—A. P. LAURIE, M.A., "Experiments on the Durability of Modern Pigments."

MARCH 16.—TEMPEST ANDERSON, M.D., "Iceland."

MARCH 23.—GILBERT R. REDGRAVE, "Manufacture and Industrial Application of Flexible Tubing."

Papers, the dates of reading of which are not yet fixed :—

"The Fisheries Department: its Position and Prospects." By J. W. WILLIS BUND.

"The Congo State." By Captain V. LOVETT CAMERON, R.N., C.B.

"Foreign Exchange." By EWING MATHESON.

"Colour Blindness." By Captain W. de W. ABNEY, C.B., F.R.S.

"Uses and Applications of Aluminium." By G. L. ADDENBROOKE.

FOREIGN AND COLONIAL SECTION.

Tuesdays, at Half-past Four or Eight o'clock ; due notice of the hour will be given :—

MARCH 15.—F. A. PEZET (Peruvian Consul General), "Peru." 8 p.m.

APRIL 5.—The Rev. JOHN McLEAN, D.D. "Manitoba and the North-West Provinces of the Dominion."

APRIL 26.—Sir EDWARD BRADDON, K.C.M.G., "The Progress of Australasia."

MAY 24.—Colonel HOWARD VINCENT, C.B., M.P., "The Extension of Colonial Trade."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m. :—

MARCH 3.—Surgeon-General Sir WILLIAM JAMES MOORE, K.C.I.E., "Indian Sanitation and the International Congress of Hygiene." Major-Gen. Sir OWEN TUDOR BURNE, K.C.S.I., C.I.E., will preside.

MARCH 24.—G. H. M. BATTEN, formerly of the Bengal Civil Service, "The Opium Question." Sir JOHN STRACHEY, G.C.S.I., C.I.E., will preside.

APRIL 7.—Dr. J. AUGUSTUS VOELCKER, "The Agricultural Needs of India."

APRIL 28.—Sir WILLIAM WEDDERBURN, Bart., "Reorganisation of Agricultural Credit in India."

MAY 19. — JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock:—

FEBRUARY 23.—J. WILLIAM TONKS, "Artistic Treatment of Jewellery: Jewel and Address Caskets." Sir PHILIP CUNLIFFE-OWEN, K.C B., K.C.M.G., C.I.E., will preside.

MARCH 29.—E. ROSCOE MULLINS, "The Decorative Uses of Sculpture." ALFRED GILBERT, A.R.A., will preside.

APRIL 12. — C. PURDON CLARKE, C.I.E., "English Brocades and Figured Silks." The LORD MASHAM will preside.

MAY 17.—GEORGE J. ROBINSON, "Decorative Plaster Work" (II.). J. HUNGERFORD POLLEN will preside.

MAY 31.—WILLIAM DE MORGAN, "Lustre Ware."

There will be no meeting on March 8, as previously announced. This will be replaced by a meeting on May 31.

CANTOR LECTURES.

Monday evenings, at Eight o'clock:—

PROF. WILLIAM ROBINSON, M.E., Assoc-M.Inst.C.E., "The Uses of Petroleum in Prime Movers." Four Lectures.

LECTURE I.—FEBRUARY 29.—*Properties and Uses of Petroleum in Prime Movers.*—Oil testing—Specific gravity, flashing point, composition—Expansion—Distillation—Vaporisation of oils—Spray-making and carburetting devices in modern oil-engines—Pressure of petroleum vapours at different temperatures—Behaviour of different kinds of oil in engine cylinder—Other properties of petroleum as heating and working agent.

LECTURE II.—MARCH 7.—*Petroleum Oil-engines.*—Heating of oils—Mixing and firing of charge in the internal combustion engine—Use of regenerator—Modes of governing—Practical tests—Study of indicator diagrams—Efficiency—Present economy and future possibilities.

LECTURE III.—MARCH 14.—*Oil Gas.*—Gas generator and internal combustion engine *versus* steam-boiler and steam-engine.

LECTURE IV.—MARCH 21.—*Oil Fuel and Gaseous Fuel for Steam-boilers.*—Safe heavy oils available—Different methods of burning oils—Injector-burners—Evaporative power of oil fuel.—Advantages and disadvantages of liquid fuel on steamships—Transport and storage of petroleum—Other uses of petroleum for power purposes.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 22 ... Geographical, University of London, Burlington-gardens, W., 8½ p.m. Mr. J. Theodore Bent, "Journeys in Mashonaland and Explorations among the Zimbabwe and other Ruins."
British Architects, 9, Conduit-street, W., 8 p.m. 1. Mr. R. Herbert Carpenter, "The Subject of Painted Glass: Introductory." 2. Mr. James Powell, "Some Details and Technicalities of the Glass-painter's Art." 3. Mr. N. H. J. Westlake, "Fairford, Winchester, and King's College (Cambridge), as Models for Modern Work." 4. Mr. Clement Heaton, "Stained Glass of the Renaissance Period, and the Use of Enamel."
Medical, 11, Chandos-street, W., 8½ p.m.
London Institution, Finsbury-circus, E.C., 5 p.m. Mr. G. L. Gomme, "Popular Superstitions and Traditions."

TUESDAY, FEB. 23 ... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. J. William Tonks, "Artistic Treatment of Jewellery: Jewel and Address Caskets."
Royal Institution, Albemarle-street, W., 3 p.m. Prof. Victor Horsley, "The Brain." (Lecture VI.)
Medical and Chirurgical, 20, Hanover-sq., W., 8½ p.m.
Civil Engineers, 25, Great George-street, S.W., 8 p.m.
Photographic, 5A, Pall-mall East, S.W., 8 p.m.
Anthropological, 3, Hanover-square, W., 8½ p.m. Mr. H. Ling Roth, "The Natives of Borneo." Part II. Edited from the papers of the late H. Brooke Low, Esq.

WEDNESDAY, FEB. 24...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Ernest Hart, "Ancient and Modern Art Pottery of Japan."
Geological, Burlington-house, 8 p.m.
Royal Society of Literature, 21, Delahay-street, S.W., 1 p.m.
Patent Agents, 19, Southampton-buildings, W.C., 7.15 p.m. 1. Discussion on Mr. Ellis's and Mr. Newton's Papers. 2. Mr. J. Imray, "Provisional Protection."

THURSDAY, FEB. 25...Royal, Burlington-house, W., 4½ p.m.
Antiquaries, Burlington-house, W., 8½ p.m.
London Institution, Finsbury-circus, E.C., 6 p.m. Mr. Shelford Bidwell, "Experimental Meteorology."
Royal Institution, Albemarle-street, W., 3 p.m. Prof. E. Ray Lankester, "Some Recent Biological Discoveries."
Electrical Engineers, 25, Great George-street, S.W., 8 p.m.

FRIDAY, FEB. 26 ..United Service Institution, Whitehall-yard, 3 p.m. Colonel J. R. Rothwell, "The Reconnaissance of a Railway: its Utilisation and Destruction in time of War."
Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting 9 p.m. Sir David Salomons, "Optical Projection."
Clinical, 20, Hanover-square, W., 8½ p.m.
Physical, Science Schools, South Kensington, S.W., 5 p.m. 1. Prof. S. P. Thompson, "Modes of Representing Electromotive Forces and Currents in Diagrams." 2. Prof. Maurice Fitzgerald, "The Flexure of Long Pillars under their own Weight." 3. Prof. J. Perry, "Choking Coils."

SATURDAY, FEB. 27 ... Saturday Lecture Society, Lecture Theatre, South Kensington Museum, S.W., 3 p.m. Rev. G. F. Browne, "Early Christian Art in England."
Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.
Royal Institution, Albemarle-street, W., 3 p.m. Lord Rayleigh, "Matter: at Rest and in Motion." (Lecture III.)

The Telegraphic Address of the Society of Arts is "Praxiteles, London."

Journal of the Society of Arts.

No. 2,049. Vol. XL.

FRIDAY, FEBRUARY 26, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

UNION OF INSTITUTIONS.

The following institution has been received nto Union since the last announcement.

Goldsmiths' Company Technical and Recreative Institute, New Cross.

Chicago Exhibition, 1893.

FINE ARTS COMMITTEE.

A meeting of this Committee was held on Wednesday, 24th inst. Present:—Sir Frederick Leighton, Pres. R.A. (Chairman of the Committee), Philip H. Calderon, R.A., F. Seymour Haden, F.R.C.S., H. Stacy Marks, R.A., Walter William Ouless, R.A., Lumb Stocks, R.A., W. Hamo Thornycroft, R.A., the Earl of Wharncliffe; with Sir Henry Trueman Wood, Secretary of the Royal Commission, and J. W. Beck, Secretary of the Committee.

PHOTOGRAPHIC DEPARTMENT.

Photographic apparatus and photographs are classified under Group 151 (instruments of precision, experiment, research and photography, photographs), which is included in the Department of Liberal Arts.

Photo-mechanical prints and processes, photogravures, &c., are classed under Group 76 (photo-mechanical and other processes of illustrating), which is, like lithography and printing generally, included in the Department of Machinery.

All the photographic exhibits, however, wil be placed together in the portion of the Liberal Arts and Manufactures Building allotted to the British Section.

Screens will be fitted up for the exhibition of photographs, photogravures, and other pictures produced by photographic methods.

For the space on these screens the charge will be 2s. 6d. per square foot, with a minimum charge of £2.

Exhibitors desiring to erect their own screens or stands can do so. In that case they will be charged for the ground they occupy according to the same scale as other exhibitors.

Proceedings of the Society.

FOREIGN AND COLONIAL SECTION.

February 16, 1892; The Hon. John X. Merriman, M.L.A., in the chair.

The paper read was—

THE FORTHCOMING EXHIBITION AT KIMBERLEY.

By Lewis Atkinson.

The idea of holding an International Exhibition at Kimberley was suggested by some of the inhabitants, and the Mayor called a meeting at the Town-hall, which was attended by all the leading townspeople. The idea being favourably received, committees were at once formed, and a guarantee fund started. It was considered that £12,000 guarantee would be quite sufficient, but the proposal was taken up so heartily that, in a very short time, about £20,000 was guaranteed, the Government giving a donation of £1,000 as a start off, the De Beers Consolidated Mines guaranteeing £2,000, the Kimberley Borough Council £1,000, the Hon. Cecil Rhodes £500, the Hon. B. I. Barnato £500, Messrs. Wernher, Beit & Co. £500, and all the large merchants about £250 each. On this side, a guarantee fund has not been started yet, but it is known that the shipping companies, banks, diamond merchants, and African merchants generally, are all willing to promote the interests of the Exhibition by making very substantial guarantees.

It was decided that the Executive Com-

mittee should consist of those only who had guaranteed the large amounts and the chairmen of the various committees, so that they might be perfectly certain that the money was expended in the best and most economical manner.

There have been Exhibitions held in the Cape Colony before, but none of so much importance, or of an International character.

RAILWAYS.

One of the many reasons that the Exhibition should be held at Kimberley is, because, thanks to the railways, it commands an exceptionally central position. It is close to the borders of the Orange Free State, Bechuanaland, and Transvaal; within reach of Natal; and the English visitors can reach it from Cape Town (647 miles) in 29 hours, or from Port Elizabeth (485 miles) in 27 hours; and travelling in the most comfortable manner in a kind of Pullman car train, fitted up with every comfort, and lighted by the electric light.

The Cape Colony has, indeed, not been lagging, when once it turned its attention to railway communication. In 1870, there were but few railways in the country; to-day, there are three trunk lines in the Cape—

	Miles opened.	Miles to be opened.
Western System:		
Cape Town to Vryburg, *viâ* Kimberley	864	41
Midland System:		
Port Elizabeth to Graaf Point, ,, Colesberg, ,, De Aar	734	
Eastern System:		
East London to Aliwal North.	292	121
	1,890	162

Total mileage, 2,052; cost, £16,261,846.

The Western system is to be extended to Mafeking.

The Midland system is being carried on through the Orange Free State to the Vaal River, and thence, through the Transvaal, to Johannesburg Gold Fields.

The year 1891 has witnessed the opening of rhe Natal-Charlestown line, in connection with which, and other railway works, the Colony spent some £4,000,000, and the opening of which was the occasion of festivities of great magnificence. Towards the close of last year Mr. Sivewright journeyed to Pretoria in connection with the railway policy of the Transvaal Government, and after carrying through some most interesting negotiations, succeeded in obtaining for the Cape Colony advantages of great importance. The Commissioner arrived in Pretoria towards the end of November, and on December 8th the Transvaal Executive gave its assent to an agreement by which the Cape Colony obtains special running powers over the Netherlands Railway Company's lines, which amount to partial control of the Johannesburg-Pretoria section of the Netherlands line, upon which a fixed tariff is to be used. The extension of the railway from Bloemfontein to the Vaal River is proceeding apace, under the Convention which received the approval of Parliament in July last. The section to Kroonstad is expected to be open for traffic early in this year. By the time the Exhibition is opened it is hoped that the railway will reach Johannesburg, but our Chairman can give you the latest particulars.

The traffic earnings on the Cape railways, which are under Government control, reached £1,986,674 in 1891, against £1,771,154 in 1890, an increase of £215,520.

The ordinary fare from Cape Town to Kimberley and back (first-class) is over £12, but the Cape Government are anxious to assist the Exhibition in every way, and are making special arrangements that visitors to the Exhibition shall do the same journey for about £3 10s., and exhibitors who take a certain amount of space will have a free railway ticket.

Telegraph Lines in Cape Colony, 1890.—Total miles of line, 4,640; miles of wire, 11,791; cost, £393,423.

Of what use, some of you may ask, can an Exhibition at Kimberley be to English trade, and of what interest to English visitors? Well, I will invite your attention to a few statistics giving a brief but clear indication of the importance of South African trade to Great Britain, and I will attempt to show that, as the Exhibition must work for the further extension of that trade, it is necessary that Great Britain should be well represented in every branch. If she does not make a good exhibit, other competitors, always anxious for an opportunity, may do her an injury. I may mention that I have already received information that Holland, Germany, Italy, Norway, France, Canada, and America are all proposing to exhibit. I will show what South Africa imports and what she exports; but before taking the trade statistics, I will give you the census return.

The Governments of the South African States

decided upon taking a census of the population during 1891. The arrangements for the Cape Colony were left in the hands of Mr. Henry de Smidt, the present Under Colonial Secretary, who earned the warmest congratulations for the admirable manner in which a census of the most comprehensive nature was carried out. Returns since made public have shown the total population of the Colony to be 1,527,224 persons, comprised as follows:—

Europeans	376,987
Malays	13,907
Hottentots	50,338
Fingoes	229,680
Kafirs	608,456
Mixed	247,806

Population of Cape Town		51,083
" Suburbs		29,063
" Port Elizabeth		23,558
" East London		6,858
" Kimberley,	28,644	39,121
" Beaconsfield,	10,478	
" Grahamstown		10,436
" King Williamstown		7,193

I may mention that Kimberley is a most cosmopolitan town, as it contains English, Scotch, Irish, Welsh, French, Germans, Italians, Norwegians, Swedes, Russians, Dutch, Portuguese, Greeks, Indians, Arabs, Chinese, Malays, and every variety of native. The Free State population was returned as 206,600, composed of 77,000 Europeans or whites, and 129,600 of other races. The census of Natal showed the population to be 543,913, the whites being 46,788, Indians 41,142, and natives 455,983, or ten blacks to one white. As to the Transvaal, £6,000 of public money was wasted in an attempt to take a census, a *fiasco* was the result, and although returns were published to the effect that the European population of the country numbers 119,128, they are not regarded as at all accurate. No census of the natives was taken.

In 1890, South Africa imported £13,780,000 worth of goods, an increase of £8,500,000 in five years; and exported produce to the value of £7,186,812, exclusive of diamonds—an increase of £2,500,000 in five years.

TRADE RETURNS OF CAPE COLONY FOR 1891.

Imports.

Merchandise	£7,518,000
Colonial Government Articles	1,054,000
Specie	10,000
Total	£8,582,000

Exports.

Produce	£3,979,000
Diamonds	4,174,200
Gold	2,781,570
Specie	14,790
Non-Colonial	181,250
Total	£11,130,810

It is estimated that the imports to Kimberley amount to over £2,500,000.

DISTRIBUTION OF CAPE TRADE, 1890.*

Imports.

United Kingdom	£6,944,022
British Possessions	630,480
	£7,574,502
Foreign Countries	896,048
Grand Total	£8,470,550

Exports.

United Kingdom	£9,692,656
British Possessions	64,318
	£9,756,974
Foreign Countries	212,191
Grand Total	£9,969,165

PORT ACCOUNTS, 1890.*

	Imports.	Exports.
Cape Town	£2,738,566	£2,064,005

Port Alfred	2,865	—
East London	1,502,046	991,093
St. John's River	612	635
Inland Stations	51,714	—
Kimberley	—	4,162,010
Totals	£8,470,550	£9,969,165

EXPORT OF WOOL, 1890.*

lbs.	Declared Value.
65,655,917	£2,196,040

I find that wool, for years the staple industry of the country, yields a return of close on £3,000,000; mohair and ostrich feathers, hides and skins, represents a yearly value of £1,250,000; copper ore, averages £650,000 per annum; and, of recent years, native gold has been gaining, in leaps and bounds, over other products.

Gold Output.—Last year the export of raw gold from the Transvaal reached £2,792,472. In January of this year the export of gold

* Similar details for 1891 not yet published.

through the Cape ports reached £330,000, as against £177,000 in January, 1890, this being at the rate of £3,500,000 a year. In 1885, the total output of raw gold was valued at £64,540; it rose to £909,000 in 1888; and, last year, it was £2,750,000, a gain of £2,500,000 in seven years. Last year no less than 52 Witwatersrant mines paid dividends ranging from 1 to 50 per cent., averaging 8½ per cent. The total capital issued in connection with the Randt mines is £14,036,540; the market value is £9,420,000. There were last year 2,260 heads of stamps in the gold-crushing batteries, and these crushed 1,275,828 tons of ore, yielding 720,980 ounces of gold, An industry which, in seven years, has doubled its returns 42 times, is entitled to our highest respect and admiration. In 1888, when the output had not reached £1,000,000, there was what is called a "boom," and some millions of English capital went out to the Transvaal for investment, often in the rashest and most foolish manner, on the bare representation of designing men. The market was inflated, people speculated wildly in scrip, and the industry itself suffered. The result was, of course, inevitable. The "boom" collapsed, like a punctured ball, involving, I am afraid, many in ruin, and giving a bad reputation to South African mines. English speculators did not suffer alone, for the whole fabric of South African trade was shaken to its centre, through the closing of three Colonial banks, the managers of which had caught the prevailing mania and gambled in shares. South Africa recovered from that blow in a most surprising manner. The Hon. J. X. Merriman, our chairman to-night, carried a Bill through Parliament, altering the banking law, guarding against a repetition of rash financing; and, to-day, the Cape and South Africa enjoy the services of institutions, conducted by able men, on the soundest and safest lines.

On October 24th last year, the deposits on current accounts in banks doing business in the Cape reached £4,660,000, and the deposits, payable after notice, totalled £3,170,000.

Not only did general commerce quickly recover from the blow, but the gold mining industry—that most seriously affected—went on increasing at still greater bounds. As we have seen, the output in 1888 did not reach £1,000,000, while last year it reached almost £3,000,000.

We have seen that South African pastoral pursuits, as represented in the supply of wool, mohair, hides, skins, and feathers, yield between £3,000,000 and £4,000,000; diamonds I will speak about later. Gold, £2,750,000; copper ore, £650,000; whilst the coal mines in Natal, Cape, and Transvaal are increasingly valuable. Mining and pastoral pursuits are, however, yet in their infancy, and the limit for expansion should be very large—how large I should not care to say.

The gold-fields in the Transvaal, Witwatersrand, and Mashonaland have yet to be fully developed. The coal deposit has been merely tapped, and the miner's occupation, is, it may safely be said, lasting.

The latest mining return of the British South African Company shows that 3,151 prospecting licenses have been issued, and that 16,355 claims have been registered. From this the mining population may be inferred, as prospecting licenses are only issued at the rate of one per man, and the latest private letters I have received says that there was little rain this season, and that large parties are flocking into the country, and that well-arranged towns are now being made.

Then, as to the stock farmer, his day has yet to come. We have not, in South Africa, such cattle ranches as they have in America, or such sheep runs as they have in Australia, but Bechuanaland invites the stock raiser, and the wide flats of Kalihari, on the authority of reliable travellers, offer good feeding ground for vast herds of cattle. Of the agriculturist we have as yet said nothing, but his occupation is one capable of almost larger development than that of the pasturist. With a fine healthy climate and a rich soil, with ports three weeks nearer London than Australian ports, the South African agriculturist has a fine prospect before him; and he has made a start in the development of a new, and, I hope, prosperous industry, in sending fruit to the London market.

Now that I have touched on the prospects of South African trade, I would ask the English manufacturers whether it will not be to their advantage to take part in an exposition of their trades. The goods chiefly in demand in South Africa are haberdashery and millinery, apparel, cotton manufactures, hardware and ironmongery, leather, boots and shoes, saddlery, machinery, cast and wrought iron, cabinet ware, oilman stores, spirits, carriages, soap, jewellery, musical instruments, guns, locks, and cutlery. In all these lines there should be good exhibits of English manufactures. I was told before I left

Kimberley that there is and will be a still greater demand for light transport, both aerial and rail, concentrating machinery, crushing machinery, rock drills, well-boring, dynamos, motors, electric lighting for mines, scientific, optical, and photographic instruments. Educational appliances are greatly needed. Gas-making machinery, both from mineral oil and coal, will also be in demand, now that we no longer depend on English coal, at about £8 15s. per ton, but have a supply, close at hand, of colonial coal, which is coming freely into the market. We shall want, also, good gas-making apparatus for lighting and cooking purposes, and the coke will be of use for smelting, as the silver mines in the Transvaal are being very greatly developed. Tents, transport waggons, portable house travelling equipments of all kinds to suit the goldseekers and hunters; also portable furniture.

In all these lines there should be good exhibits of English manufactures. People who have made fortunes prefer making a home there to returning to this country, and their houses are fitted with every luxury and comfort. At the last Paris Exhibition many visitors from the Cape bought works of art, pictures, furniture, and have them in their homes now. These houses now are nearly all being supplied with the electric light.

Trade does not always follow the flag, it sometimes goes into foreign bottoms, and our friends across the water, both in Germany and in the United States, are keen competitors, with a reputation for pushing their own interests. I have received letters from people in Canada not only to say that they wished to exhibit, being fully alive to the fact that this offers a splendid opportunity of opening business with a sister colony, but stating they hope to make up a large party of Canadian manufacturers, merchants, and agriculturists, to visit Africa during the Exhibition, and to find out the best way to push their businesses and in many cases settle in the country. I would point out that Colonials will go the Exhibition to learn something, and it may safely be predicted that every English exhibitor will have cause to be thankful that he displayed his goods. From every part of South Africa will flock people of every trade and occupation, bent on finding out machinery which will lead to the saving of labour or the development of industry. Every bit of machinery, from an elaborate stamp battery to a sewing machine, every article of workmanship, and every manufacture in use in South Africa, together with rare pieces of art, tasty millinery from West-end houses, and all the various ornaments and luxuries that go to make up the pleasure of living, as well as those that provide the material for living on, and those that help to provide the means to live at all, all these will be carefully examined by appreciative judges, by miners and farmers, by merchants and sportsmen, by wives and sweethearts, all bent upon purchasing something. The manufacturer who does not exhibit goods that are in demand in that large and growing country will regret his want of enterprise.

The Exhibition, as I have said, is being well supported by the Cape Government. They started by giving a donation of £1,000, and have arranged that the Exhibition shall be a bonded warehouse; therefore, there will be no duty charged on unsold exhibits.

The Government have made arrangements with the railway department to carry all goods intended for exhibition to and from Kimberley free of charge, provided they remain the property of the exhibitor. If, however, any exhibit brought by rail is sold, the exhibitor will have to pay the ordinary rates.

It is hoped that the Government will make arrangements for caretakers in charge of exhibits to be allowed to travel free per rail second-class (or, upon paying the difference, travel first-class), provided that they have paid for, and occupy, a space of not less than 30 square feet, and, further, that the exhibits of which they are in charge are in the same ownership on the return journey.

The Government are going to lay a siding from the main line so that the railway will go straight into the Exhibition. The Government have decided that during the Exhibition they will run cheap trains from Cape Town to the Exhibition.

The *personnel* of the Exhibition is as follows:—

President.—His Excellency Sir Henry Brougham Loch, G.C.M.G., K.C.B., &c., Governor of the Cape Colony, and Her Majesty's High Commissioner.

Vice-President.—The Hon. Cecil John Rhodes, Premier of the Cape Colony.

Patrons.—The Right Hon. Lord Knutsford, G.C.M.G., H.M. Secretary of State for the Colonies; his Excellency Lieut.-Col. Sir Charles B. H. Mitchell, K.C.M.G., Governor and Commander-in-Chief of the Colony of Natal; his Honour Sir Sidney G. Shippard, K.C.M.G., Administrator of British Bechuanaland; his Honour Lieut.-Col. Sir M. J. Clarke, R.A., K.C.M.G., Resident Commissioner, British

Basutoland; his Honour S. J. P. Kruger, President, South African Republic, and the Members of the Volksraad; his Honour F. W. Reitz, President, Orange Free State, and the Members of the Rand; the Hon. J. W. Sauer, Colonial Secretary; the Hon. J. X. Merriman, Treasurer of the Colony; the Hon. J. Rose-Innes, Attorney-General; the Hon. James Sivewright, Commissioner of Crown Lands and Public Works; Sir Charles Mills, C.B., K.C.M.G., Agent-General for the Cape Colony; the Hon. Sir Gordon Sprigg, K.C.M.G.; the Hon. Sir Thomas Upington, K.C.M.G., Q.C.; Sir John Henry de Villiers, K.C.M.G., Chief Justice; the Hon. Mr. Justice Smith; the Hon. Mr. Justice Buchanan; Sir Jacob D. Barry, Judge President, Eastern Districts Court; the Hon. Mr. Justice Jones; the Hon. Mr. Justice Maasdorp; the Hon. Mr. Justice Laurence, Judge President, High Court, Kimberley; the Hon. Mr. Justice Solomon; the Hon. Mr. Justice Cole; the Mayors of the various towns of the Cape Colony, Natal, and the South African States; Captain Hollis, Consul for the United States; A. Ohlsson, Esq., Consul-General for Sweden and Norway; C. H. Knight, Esq., Consul for Belgium; E. Von Treskow, Esq., Consul-General for Germany; A. De Carpini, Esq., Consul for Italy; E. A. De Carvalho, Esq., Consul for Portugal; Chamber of Mines, Johannesburg.

Chambers of Commerce.—Kimberley, Cape Town, King William's Town, East London, Port Elizabeth, Durban, Maritzburg, Bloemfontein, Pretoria, and Mafeking.

In London, every assistance and support is being given to the Exhibition. The Right Hon. Lord Knutsford, G.C.M.G., H.M. Secretary of State for the Colonies, is a patron, Sir Charles Mills, C.B., K.C.M.G., is the Chairman of the Executive, as the Cape Government asked him to give his valuable aid. Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., C.I.E., is on the Executive, and he, as you know, is the grandest organiser. Every exhibition has been a great success whenever he has been at the head of it, and I have to thank him for the very valuable assistance he has rendered us already; then we have Sir George Chubb, a gentleman of great exhibition experience, who has given valuable assistance.

Sir Donald Currie, K.C.M.G., M.P., as representing the De Beers Company, has very kindly taken in hand the Fine Art Section; and Sir Frederick Leighton has kindly consented to act on the Fine Art Committee; and there is little doubt that fine art will be better represented than it ever has been in Africa before.

Mr. H. A. Hedley, who has for many years been connected with exhibitions, and was the successful manager of the first Edinburgh Exhibition and the Glasgow Exhibition, is also giving valuable practical help. The two mail companies are represented by Mr. Farmer, for the Union Steamship Company, and Captain Wisely, for the Castle Company. The African merchants are represented by Mr. G. M. Mosenthal, of Messrs. M. Mosenthal, and Mr. J. Paddon, of Messrs. Hill and Paddon. Mr. C. Posno, represents the next largest and wealthiest company in Kimberley and De Beers, being chairman of the London and South African Exploration Company, and the North-East Bultfontein Diamond Mining Company; and the Press is represented by Mr. E. P. Mathers, editor of *South Africa;* and, on the London General Committee, we have Sir Somers Vine, a practical exhibition gentleman, and some of the leading African merchants.

The shipping companies have decided to assist the Exhibition in every way, and the British and Colonial Steam Navigation Company (Messrs. Bucknall Bros.), 22, Crutched-friars, have offered the most generous terms, and such that have never been given to any other Exhibition. They are prepared to convey exhibits outwards at current rates, and to bring back to Great Britain any unsold exhibits that were taken out by them free of homeward freight, and refunding the amount previously paid for outward freight on such unsold exhibits. Therefore, exhibitors will have their goods carried by ship 6,551 miles, by rail, 485 miles, and, if not sold, the same distance back, free of charge.

The Castle Mail Packets Company (Donald Currie and Co.), 3 and 4, Fenchurch-street, E.C.; Union Steamship Company, 94 and 96, Bishopsgate-street Within, E.C.; South African Line, Billiter-house, Billiter-street, E.C.; International Line, Rochester-building, 138, Leadenhall-street, E.C.; Clan Line, Leadenhall-buildings, Gracechurch-street, E.C., have intimated that they will be prepared to make special arrangements with exhibitors for the conveyance of their exhibits outwards or homewards.

Messrs. Divine Gates, of Cape Town, have informed me that they are appointed the official agents at Cape Town, and will only be too pleased to help all exhibitors and visitors

to the Exhibition. Messrs. Rodwell and Co., of Port Elizabeth, are the official agents at that town, and will forward all exhibits on by train, making a small charge, and also the dock charges.

The Exhibition buildings will be situated in the Botanic-gardens. The main buildings will cover 50,000 square feet, and there will be a gallery which, in Africa, will be a novelty. The building has one main avenue, and off this four separate wings, to contain the British, Continental, Canadian, American, and Fine Art sections. I do not know for certain what the building will be built of, but expect it will consist of wood and iron, and special arrangements will be made to protect the Fine Art Sections. It has been decided not to use glass for the skylight, but "Duroline" from the New Wire Wove Roofing Company.

The machinery will be put in a separate hall, and this will be one of the great features, as the Mining and Machinery Committee are giving their hearty support, and are going to award gold, silver, and bronze medals, also diplomas, and have forwarded to me the conditions for competition in rock drilling, &c.

The buildings are to be erected by May 15th, and I have received instructions that the De Beers Consolidated Co. have made arrangements to buy the main-building and machinery-hall really before they are erected.

The Exhibition offers a splendid opportunity for manufacturers of machinery to increase their business in South Africa, as the Mining and Machinery Committee consists almost entirely of gentlemen who are mine managers or in charge of machinery. Johannesburg intended holding an Exhibition about August, this year, but abandoned it, and they have now formed a committee there to help the Kimberley Exhibition, and these gentlemen will all be now at the Exhibition, and will not only practically test the machines, but will be able to find exactly the sort they require. This morning I received a cablegram from Kimberley to say Randt Chamber of Mines officially offer gold medals for machinery. We have their hearty support.

Agricultural machinery and implements will be greatly appreciated, as the Executive are now arranging to have a large Intercolonial Agricutural Cattle Show, and the Pretoria Agricultural Society have promised to give every assistance to the Exhibition, and also render pecuniary aid. The Executive are also arranging with the Government to try and have a grand review of all colonial volunteers, so that camping, equipments, guns, &c., would be thoroughly appreciated; and it is intended that all scientific meetings, conferences, &c., shall take place during the Exhibition.

The Exhibition will be opened on Sept. 1st, and remain open for above three months. The committee reserve to themselves the right to extend or shorten the period during which the Exhibition shall remain open.

An influential Committee, under the presidency of the Mayor, has been formed to deal with the accommodation of exhibitors and visitors during the Exhibition.

All the larger exhibits, or such as require special fittings, must be delivered not earlier than the 15th of July, nor later than the 15th August, and must be accompanied by attendants qualified to place them in position, unless special arrangements are made. Smaller exhibits can be delivered after that date, but not later than the 25th of August, 1892. All must be arranged and ready for exhibition before the 1st September. Exhibits proffered after these dates may be received, but no guarantee is given that they will either be catalogued or submitted to the jurors.

The charge for space will be as follows:—For floor space (other than machinery in motion), not exceeding 25 square feet, 5s. per square foot; for floor space exceeding 25, not exceeding 50 square feet, 4s. per square foot; for floor space exceeding 50, not exceeding 100 square feet, 3s. 6d. per square foot; for floor space exceeding 100, not exceeding 200 square feet, 3s. per square foot; for wall space, half the above rates; for outside space for sheds, 2s. per square foot.

The Executive Committee reserve to themselves the right to refuse any exhibit, without stating the reason for so doing. If no space is allotted the money paid will be refunded, and where only a portion of the space applied for is granted, a proportionate amount will be retained and the balance refunded.

British and Foreign applications will be received in London until March 1st, 1892. A sketch of the space required, and an elevation, showing the character of the exhibit, will greatly assist in the arrangement of the spaces. Whatever vacant space exhibitors require around their exhibits, beyond the usual passages, must be paid for. As the space is limited it would be advisable to send in the application as early as possible. Applications for space for machinery in motion must be made on special forms, which will be supplied on application to the London office.

The London Committees, whilst cordially acting in conjunction with the committees in Kimberley, and the Manager, in forwarding, so far as they can, the interests of the Exhibition, and of intending exhibitors and others, by supplying prospectuses and applications for space, and otherwise assisting and facilitating the objects in view, desire to make it known that they will not be responsible either individually or collectively for any loss, damage, or expenses of any kind whatever connected with the Exhibition, or with the preparation and transmission of exhibits or otherwise by whomsoever incurred.

All information can be had at the Agent-General's (Sir Charles Mills) offices, 112, Victoria-street; or of myself, at the Exhibition offices, 3 and 4, Fenchurch-street.

Kimberley is situated 4,050 feet above sea level. The mean temperature is 70° in summer, and 50° in winter. It is a well-planned town, with twenty miles of streets, and attractive shops. The houses are all built of brick, improved drainage, and a plentiful supply of water from the Vaal River. The town is lighted by the electric light. The Kimberley Club is the most roomy and best arranged in the colony, and the able secretary, Captain Tyson, looks well after the comfort of all members and visitors.

There are four principal diamond mines. Kimberley Mine, which is situated in the town; the De Beers Mine, also situated in the town, close to the Exhibition-grounds; Bullfontein Mine, 2½ miles to the south of De Beers, and Du Toits Pan Mine (close by these two), are situated in Beaconsfield.

The De Beers Consolidated Mines have now practically the four mines in their hands, and have lately purchased the Wessleton Mine.

For 16 years following 1867 there were no accurate official returns of the exact weight and value of diamonds produced in the several mines. Since that date careful monthly statistics are collected by the chief of the detective department at Kimberley. But even now, notwithstanding the stringent penal laws against illicit diamond dealing, it is well known that a very large per-centage of the gems do not reach their lawful owners.

Taking the best available estimates for the years from 1867 to 1882, and the official returns for the subsequent years up to December 31st, 1891, the total value of diamonds produced in the Griqualand West Mines reaches the enormous sum of over £57,000,000 sterling. For the past year the value exported was £4,174.200.

Some authorities believe that the actual produce of the mines during the 25 years of working is at least one-fourth more than the official returns, so that, if that be correct, we get the enormous total value of £71,000,000 sterling; and there is no indication of any diminution of production.

The effects of the diamond discovery on the commercial interests of Cape Colony, it is hardly necessary to say, have been most marked. It occurred at a time when the colony was suffering from severe trade depression, which it gradually dispelled, as is shown by the revenue returns, which have since that period steadily risen from £617,826, in 1867, to £4,430,050, in 1889-90, per annum.

At the present time about £2,000,000 sterling is spent in wages annually by the De Beers Company at Kimberley.

It is not my business to-night to trace the history and uses of the diamond, and if it were, far different, let me say, would be my conclusions from that drawn by Lord Randolph Churchill, who seemed to find no other reason or motive for the diamond industry than woman's vanity and its gratification.

There is no doubt that the diamond industry has helped civilisation, increased present prosperity of South Africa, developed the railway system, brought capital into the country, and, better than that, brought new life and fresh blood from every part of the world—from America, Australia, from the Continental countries, and from Great Britain, men flocked to the new Eldorado. In that great rush there naturally were included many rogues, but each country contributed some of its best material, and South Africa has not ceased to appreciate the services of some of these. In mentioning one name which is most conspicuous, the Honourable Cecil J. Rhodes, present Prime Minister of the Cape, I am reminded of the fact that the present splendid position of the diamond mines is greatly due to his foresight, and he is pursuing the same work now in the development of Mashonaland and Matabeleland.

Before leaving the De Beers Consolidated Mines, I should like to say that every member of that company is helping the Exhibition; and at the annual meeting, held in Kimberley, September 24th, 1891, Mr. B. J. Barnato, acting chairman of the company, in his speech to the shareholders, said these words :—

"Gentlemen, before drawing my remarks to a close, there is one subject which I should like to mention briefly, because our company will be inti-

mately associated with it, as a project which is calculated to attract a great deal of attention to the products, the industry, and the enterprise and resources of South Africa. I refer to the Exhibition which is to be held in Kimberley towards the end of next year, and the exact title of which is comprehensive enough—the South African International Exhibition, Kimberley, 1892. You are aware, gentlemen, that our company has placed a certain sum upon the Guarantee Fund for that undertaking, and we have done so for two chief reasons. The first is that we recognise the propriety of such an institution as ours, and so powerful an industry as the diamond industry, assisting by every means in our power an undertaking of so useful and beneficial a character. And in the second place, however much we may be convinced as to our almost exclusive ownership of the diamond wealth of the world, it is but right that we should take every means in our power to instruct and educate the people, as it were, in the extent and magnitude of our mining operations, the splendid appliances here in use in Griqualand West for the winning of our diamonds, and, in fact, the whole economy and method of an industrial and productive and financial corporation which has not its equal in the whole world. In aiding and supporting this proposed Exhibition we thus not only do good to the town, which we are ever anxious to do, but we shall also let the world know by practical means, and best of all, by machinery in motion and by the actual manipulation of blue grounds and diamonds, from start to finish, what labour, what outlay, what anxiety, care and forethought, are required in the finding of those precious gems which I hope will in a short time yield a greater profit than ever to the shareholders of our company. Not only have we as a company subscribed to the Guarantee Fund of the Kimberley Exhibition, but many of us individually have done so, and I am sure that shareholders generally, whether resident here or in Europe, wish this admirable scheme the most brilliant success."

The De Beers Co. are supporting the Exhibition in every way, as Sir Donald Currie represents them in London on the Executive; three of the directors at Kimberley, Messrs. B. J. Barnato, L. Breetmeyer, C. E. Nind, are on the Executive there; Messrs. Gardener T. Williams, general manager; L. J. Seymour, the engineer; and Mr. H. Craven, the secretary, is treasurer.

What attractions are there to induce English visitors to the Exhibition ?

First, there is one of the finest sea voyages in the world, and both the Union and Castle Mail Companies will act very generously in reducing the fares. Messrs. Cook, the world-renowned tourists' agents, take charge of the visitors, as they are appointed the passenger agents, and they will undertake the arranging of tours for visitors. Then there is the lovely scenery around Cape Town; then up to Kimberley, and, besides seeing the Exhibition, the directors of De Beers will kindly allow all visitors to the Exhibition to inspect the diamond mines and see the whole of the diamond industry, and if they desire it, they can then go on to the gold-fields, then on to Natal, and back home.

Mr. T. W. Goodwin, ex-Mayor of Kimberley, is appointed the African agent, and has visited a large number of the African towns, and has received every support.

If ever the late Prince Consort's idea of an Exhibition were realised, it will be in this case, as it will advance education, increase business relations with all countries, and greatly tend to increase that good feeling that already exists between the various Governments and people in South Africa.

DISCUSSION.

Sir PHILIP CUNLIFFE-OWEN, K.C.B., K.C.M.G., C.I.E., thought every one would agree with him that they had listened to a most interesting paper. As an old member of the Society of Arts, he felt very much pleased that they had had the honour of having a distinguished statesman in the chair that evening; and, as a member of the London Executive Committee of the Kimberley Exhibition, he congratulated them that the chairman had shown so much interest in the proposed Exhibition as to be present that evening. He (Sir Philip) felt honoured at having been asked to be a member of the London Executive, and to act under his old friend, Sir Charles Mills, with whom he had had the pleasure of working in connection with the Colonial and Indian Exhibition. The strength of the London Executive was the worthy chairman. As an old exhibition man, he might say that the outcome of all exhibitions was business; and if British manufacturers would only exhibit their wares at the Kimberley Exhibition, he was sure they would meet with a fitting reward. He had no doubt that the invitation to manufacturers would be loyally responded to; and he was certain that all those who exhibited would have reason to be grateful for the sacrifices they made, as they would establish a business in Kimberley which would be to their own benefit, and to the lasting benefit of this country. He had had the pleasure of working with Mr. Atkinson on many occasions, and knew that he was capable of doing all that he promised.

Mr. BEWICK said he had been very much interested in the paper, and from what he knew of South Africa, he was sure that all visitors to the Exhibition would thoroughly enjoy themselves. He should be glad if

Mr. Atkinson would give them some assurance that visitors would be able to find sufficient hotel accommodation.

Sir PHILIP CUNLIFFE-OWEN said he had no doubt that if Messrs. Cook had undertaken to look after the travelling public, there would be sufficient accommodation provided.

Sir CHARLES MILLS, K.C.M.G., C.B., said the subject of accommodation had been fully considered by the Executive Committee in London, and he had not the slightest doubt that accommodation would be found for all visitors.

The CHAIRMAN, in proposing a vote of thanks to the author of the paper, said that with regard to the question of accommodation, it must be recollected that the Cape was not like London, and visitors could put up with a trifle less accommodation there than here, owing to the excellent climate. He thought Mr. Atkinson was very courageous to have read a paper at all about the colonies at the present time, seeing that in England there were waves of feeling with regard to them. Sometimes there was a tremendous gush in favour of the colonies, and at other times there came a sort of blizzard. At the present time the colonies were suffering from the latter. During the jubilee year enough could not be said in favour of the Australian colonies. They were urged to enter into all kinds of expenditure, which they did, and two or three years after they were told that they were running too far. A good deal of this feeling came from an insufficiency of knowledge, and in his opinion the Exhibition was about the best thing calculated to remove this feeling. If people knew more about the colonies, he did not think there would be this extraordinary feeling that the colonies were going to set the world right, neither would they have the occasional cold snaps. He was perfectly certain at the present time, if there were more knowledge of the colonies they would not have the extraordinary feeling of depression with regard to the colonial securities. Anyone who took the trouble to study the colonies and their wonderful resources, would see how well able they were to pay their way. At the Cape the people were a steady-going class with regard to financial operations, and when they found that the British public were not ready to lend them money, they lent it to themselves. The depression now going on would have a good effect, if it merely taught colonists to be more self-reliant, The colony which he had the honour to represent had assisted itself; at the present moment they were about to raise a loan to the extent of £1,000,000, having already lent themselves £2,000,000 upon a previous occasion, though that fact was not known in England. About one-eighth of their whole debt would be held by the people and institutions of the colony. That was a healthy state of affairs, and he hoped the Australian colonies, which had far more resources than the Cape, would imitate them in that respect. If all the British colonies did that, they would not find capitalists in London looking askance at them. Mr. Atkinson had given them so many figures that he would not attempt to add to the number; but he must just mention that the Cape Colony managed last year to export about £3,000,000 worth more goods than it imported. This was a healthy sign for a borrowing colony. A remark had been made as to there not being enormous sheep farms in the colony as in Australia. This was very true, and he was glad to say it was so, for instead of having a few squatter kings, as they were called in Australia, the farms in the colony were each managed by their owners. This developed the resources of the country. More white population was needed, and in this respect the Exhibition must do a great deal of good. There was no need to try and induce people to come and develop mines, for they would come fast enough. The diamonds spoke for themselves, and the gold was now beginning to speak. What were wanted were those who would come and settle on the land. One industry which, he believed, was destined to have a very great future, was the fruit industry. This was attracting many people to Australia, and also to California and Florida. Quite lately, this industry had been put on a commercial footing, by the successful importation of peaches and grapes in the English market, which had been sold at a good profit, leaving a handsome return for the growing. This industry was capable of a very great future indeed, and it left an opening to many young men, with a small amount of capital, and who liked a country life. In connection with this subject, he might be permitted to say that he viewed with a certain amount of alarm a statement that lately appeared in the newspapers, that "General" Booth was proposing to select the Cape Colony as the place for his first experiment of an over-sea colony. He felt bound to say that the population of the Cape Colony would resent this very much indeed, for a worse place could not have been selected for the experiment. It was a place where drink was cheaper than in any other part of the world; and as the people to be sent to found the new colony would doubtless be taken from a class which had not succeeded here in consequence of intemperate habits, it would be folly to send them to a warm country where drink was so cheap, and where there was a great black population of no morality at all, and where among the great industries was gold mining, which was of a gambling character. In the name of his Colony, he felt bound to protest against the experiment being made. He did not know why "General" Booth, who had not been received with any amount of enthusiasm at the Cape, should have selected this Colony; and he hoped that he might re-consider his decision. He did not wish to cast any stones at the extraordinary manner in which the propaganda was arried on, but, while wishing well to the scheme,

he must enter a protest against the Cape being selected as the proposed field of the operation. Coming back to the paper, he thought the Exhibition would be a means of spreading information with regard to South Africa. The one thing wanted, to judge South Africa impartially and fairly, was to have more knowledge of it, which would be obtained from the Exhibition. Mr. Atkinson had already shown himself to be a most successful man at this kind of work, and the success of the diamond industry at the Colonial Exhibition was largely due to him.

The vote of thanks was carried unanimously.

Mr. ATKINSON, in reply, said that the hotel accommodation had been the subject of great consideration by the Executive Committee at Kimberley, and before he left the colony he was informed by the hotel keepers that they would support the Exhibition by keeping prices down to the ordinary tariff. The Executive Committee in London knew that it was a most important matter that visitors should be comfortably housed, and this week he had received a letter from the Kimberley Executive Committee to the effect that a committee had been formed, of which the Mayor was chairman, to look into the question of hotel accommodation. He had not the slightest doubt that there would be sufficient accommodation for everyone. The Exhibition was sure to be a success, as all the leading firms had promised to exhibit.

APPLIED ART SECTION.

Tuesday, February 23rd, 1892; Sir PHILIP CUNLIFFE-OWEN, K.C.B., K.C.M.G., C.I.E., in the chair. The paper read was "Artistic Treatment of Jewel and Address Caskets," by J. WILLIAM TONKS. The paper and discussion will appear in next week's *Journal*.

ELEVENTH ORDINARY MEETING.

Wednesday, February 24, 1892; Professor WILLIAM ANDERSON, F.R.C.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Blanchard, Mark Henry, Bishop's Waltham, Hants.
Courtenay, J. Irving, 1, Essex-court, Temple, E.C.
Farlie, John Burke. 128, Eglinton-road, Plumstead, Kent.
Goodenough, Lieut.-General William Howley, C.B., Blomefield-house, Shooters'-hill, Kent.
Langton, Alfred, Deptford Pier, S.E.
Macpherson-Grant, John D.L., Ballindalloch, N.B.
Smith, Henry Wells, 8, Norfolk-row, Sheffield.

The following candidates were balloted for and duly elected members of the Society:—

Ashburner, Lionel Robert, C.S.I., 9A, Gloucester-place, Portman-square, W.
Hervey, Hubert J. A., 12, Lowndes-street, S.W.
Hughes, John, Chester, and 16, Great George-street, S.W.
Jex, Edward, 27, St. Mary-at-Hill, E.C., and the Dukeries, Springfield, Chelmsford, Essex.
Riekmann, Adolph, 59, Knightrider-street, E.C.
Sessions, Frederick, Russell-house, Gloucester.
Simpson, Edward Henry, 100, St. Martin's-lane, W.C.
Smith, W. A., Houghton-house, Arundel.

The CHAIRMAN, in introducing the reader of the paper, said it was some five years since Mr. Hart instructed them by a series of lectures upon almost every form of Japanese art, and since that time he had visited Japan. Mr. Ernest Hart had now seen the various *fabriques* and studied the production of Japanese art from the point of view of a connoisseur and collector. The best connoisseur was the collector, and the best of all collectors was the connoisseur, both of which qualifications Mr. Hart possessed.

The paper read was—

ANCIENT AND MODERN ART POTTERY AND PORCELAIN OF JAPAN.

BY ERNEST HART.

Member of Council of the Japan Society.

I had the honour of dealing with the subject of Japanese art work before an audience composed of the members of the Society of Arts in May, 1886. The time which I was able to devote then to Japanese porcelain and pottery was very limited. It has been, however, a satisfaction to find that the summary classification of schools and masters which I ventured to present has been since widely adopted both here and in Japan. That part of my lecture which related to pottery and porcelain has been reproduced *verbatim* by that enlightened and appreciative student and writer on the art work of Japan, Mr. Marcus Huish, who did me the honour to apply to me for authority to do so, in his excellent and popular handbook of the arts of Japan; and, when I recently visited Japan, the first book put into my hands, or, rather, laid on the table of my room, on arriving at the hotel in Yokohama, was a complete report of the lecture published by Mr. Deakin, whose enterprise and taste has done so much to favour the best work of the modern Japanese artist, and whose collections at once open to the traveller in Japan a full and very attractive view of the best work of the best

artists of to-day. I was further encouraged by finding, later on, that a good deal of the text of the lectures which I gave in this theatre, and which were re-printed from the *Journal*,* had been translated into Japanese, and were extensively circulated among the Japanese, and valued by them as a handbook and critical discussion of the merits and characteristics of the schools, periods, and masters of old Japan, in a little book which I have here in my hand. The edition is now nearly exhausted, but I still frequently receive applications for copies—(I did so this week from the Leyden Museum)—and these are often accompanied by such cordial assurances from amateurs and students that they rely largely upon those lectures and the accompanying index of authors and signatures as their guide, that I am induced once more to take up some parts of this interesting study. I have greatly added to my imperfect knowledge of this great subject, and largely added also to my collection of specimens of the finer varieties of old work during a recent visit to Japan, in which I had the opportunity of examining an immense number of specimens in public and private keeping, and of selecting from some choice private collections examples of the rarer kinds of work, seldom seen in Europe. For these opportunities I was largely indebted to the peculiar kindness of leading members of the Government, among whom I owe my acknowledgments to Count Okabê, Count Kuki, the head of the department of fine arts, an accomplished and devoted curator of the art treasures of Japan, and to Mr. Hamao, the Minister of Education. In no less a degree was I indebted to the kindness of Mr. Okakura, the head of the art schools and acting chief of the museum at Uyeno, whose European studies have been added to Japanese erudition and taste, and to Captain Brinkley, of Tokio. Captain Brinkley is no less remarkable for his thorough accomplishment as a Japanese scholar, than for his enthusiasm, judgment, and research as a critic and collector. He is *facile princeps* in many departments, but as as authority in keramics he stands alone. We are all expecting his promised *magnum opus* on the subject, of which I saw the beautiful plates and a large part of the letter-press.

Armed with official recommendations to the Governors of the provinces, and supplied by them with courteous attendant officers (Mr. Kobayashi and Mr. Maeda), who had opened to me all the temple stores, the private collections, the priest's godowns, and the public treasures; and, aided by the critical judgment of some of the most acute of Japanese experts, I was able to enjoy, in the course of a few months, such a revelation of the variety, originality, and richness of Japanese art work as was beyond imagination, and could hardly otherwise have been achieved in the course of years.

Circumstances also enabled me to become possessed of the private collection of old Satsuma, which had been slowly accumulated, for his own delectation, by Mr. Maizan Tabui, whose name is celebrated throughout the world as the most accomplished of Satsuma artists; while the kindness and energy of Mr. Wakai, of Tokio, the inspirer of the great work of M. Gonse, and the parent of the best European collections, put me on the track of some of the finest few remaining keramic treasures of Japan still available to the enterprise of European collectors. For so few now are the available masterpieces of old work, that the systematic search for them on the spot for the European market has almost ceased. Little arrives here but skilful forgeries of old work or the dregs of the market, after the Japanese Imperial household, the native collector, or the agents of the public museums at Tokio or Osaka have had their choice; and the skilled French collectors who used to traverse Japan have been withdrawn.

I wish I had time to describe to you to-night, as I hope to describe at some time elsewhere, the excitement and the humours of the hunt for *antiques* in Japan. A Japanese auction of the old style at Kioto is a subject worthy of the pencil of a Hogarth: the unfailing courtesy of the modern Japanese curio dealers—that is to say, of those who supply the globe-trotter—is only equalled by their profound and ingenious duplicity, their unblushing but imperturbable humbug. Suffice it to say, that out of thousands upon thousands of pieces of pottery which I saw offered for sale and sold to globe-trotters, rarely one per cent. were genuine, or in any sense valuable; and but for the honesty and trustworthy skill and capacity of some of the few "old Japanese" dealers, such as Wakai, Daisho, Daizen, Fukiu, and Fukuda, and the opportunities from private collections in all parts of Japan, which I owe to the kindness of the introductions from the gentlemen I have mentioned

* Lectures on "Japanese Art Work," by Ernest Hart, delivered before the Society May 4, 11, and 18, 1886, with a catalogue of objects exhibited, and an Index of Japanese artists. London: 1886.

above, I should have come away nearly empty-handed. As it was, I was able—after curious adventure, and after having to read a very severe lesson before official authority to one of the larger dealers—to bring away, after three months' incessant hunting through accumulations in out-of-the-way places and the available stores of all the dealers, and collectors, and connoisseurs, lay and ecclesiastical, nearly a thousand specimens in all of objects in different departments of ancient art, which had been passed through the most critical tests.

The keramics of Japan are confessedly the most ancient and the most characteristic of its art products, and those which have most immediately and extensively influenced European work. Our literature has been enriched by our Chairman, by Mr. Gonse, and others, with monographs on glyptic and pictorial art, while pottery and porcelain have not been dealt with in so authoritative or satisfactory a manner. I propose, therefore, to-night to take a further step in that direction.

I wish to put before your eyes authentic specimens of the leading kilns of Old Japan; examples of the most characteristic works of its potters; and illustrative varieties of the peculiarities of the older glazes, paste, and decorative style, to which the Japanese attach most importance, and which seem to me most to deserve the attention of the artistic connoisseur. For the description of them and their historic details, I shall rely wholly upon the dicta of Captain Brinkley, whose words I shall use throughout and whose authority I shall follow, for I am persuaded we shall nowhere else find so safe a guide. The details furnished in his paper in "The Chrysanthemum," in the extracts illustrating his exhibited collection in New York, and in his chapter contributed to the works of Mr. Chamberlain and Mr. Norman, furnish a body of information which leaves little to be desired, except that they be, as we are promised that they will be, collected, condensed, and illustrated in a great forthcoming work. Meanwhile, in directing your attention to the specimens I put before you, you will please remember that it is for the most part Captain Brinkley who is speaking, and that it is to his erudition and judgment that we are indebted for the text by which I ask you to judge the examples which your eyes will enable you to study. This is, to-night, rather a demonstration than a lecture; the researches, and largely even the words, are due to Brinkley. I want you to distinguish and to judge the things described. I am very sorry that the exigencies of space in the lecture theatre compel me to restrict my selection to a few leading examples of each ware. But as the Japan Society—newly formed since I undertook this paper—promises exhibitions of characteristic art productions, I hope that, before very long, an exhibition of Japanese keramic art wares may be arranged, which may afford more prolonged and complete studies of Japanese keramics than we can have to-night. Needless to say, too, that to any sympathetic lover or student of Japanese keramics it will always be a pleasure to me—as it is to every enthusiastic collector—to afford opportunities of the further study and examination of the pieces in my rather extensive collection.

Let us pass, then, to what is before us, and of course we must begin at the beginning. Yet of the true beginnings of Japanese pottery, of the prehistoric tomb and house pottery, of the dug-up specimens of sacrificial ware, of the earliest and rougher wares of the Cha-no-yu, in other words of purely archæological specimens, I have nothing to-night to say. You will find much about them in all the books, in the writings of Franks, of Ninagowa Noritani, and of Moise, and Bowes, and in the native handbooks. I have numerous specimens of them, and you will find them in the British Museum and South Kensington, the latter otherwise very ill supplied with the finer specimens of old Japanese keramic ware. But I do not propose, to-night, to speak to you of these earliest beginnings, or of this esoteric ware. I am dealing with what we may describe as the decorated art pottery and porcelain of old Japan, using those words in our European sense, and putting aside for the moment the traditions of the old Cha-jin.

I begin, then, here with the blue and white porcelain of Shonzui Gorodayu. It was in 1530 that Shonzui travelled to China to learn some of the secrets of the kilns of Foochow: he sojourned there for some years, and learned the art of mixing the pastes, of decorating with cobalts under the glaze, and *au grand feu*. It was in the best period of Chinese work, and he attained considerable skill. He returned to Arita (province of Hizen), bringing with him the materials as well as the secrets of the art; but as Japan did not at that time know of its own vast treasures of kaolin, he was sparing of his material, and he made only small specimens, for the most part with a diaper decoration. They are exceedingly scarce, but I have here three authentic specimens, one of them evidently made by him in

China. The small and choice specimen with pierced cover I secured at a private sale at Kyôtô—one of the most picturesque scenes that I can remember—in competition with a large company of the best connoisseurs of Japan, who all sat decorously in small coteries, or tea-parties, in screened compartments, squatting on their mats. We bid solemnly and decorously by writings dropped into a ballot-box, and when the ballot-boxes were opened, and the little pot was adjudged to me, Japanese politeness bid the attendants raise a hearty cheer, although some of them subsequently tried to tempt me to part with the little treasure, which they thought ought to be kept in a Japanese collection.

Imari or Hizen Porcelain, Decorated with Enamels over the Glaze.

Shonzui, says Brinkley, from whom I now begin my extracts, on his return from China, about 1516, settled at the village of Arita, in Hizen. The nearest port to Arita is Imari, a name familiar to all collectors as the common appellation of Japanese porcelain. After having exhausted the materials which he had brought with him from the Po-yang Lake, he failed to discover any suitable substitutes in Japan. Yet, strange to say, in the spur of the very hill which rose over the village where he lived, inexhaustible quantities of the much-desired clay were waiting to be used. His pupils and successors, Gorohachi and Goroshichi, were not more fortunate than himself, and the factory at Arita had almost lost the reputation acquired from his productions, when there arrived there one of the Korean experts, whom the Japanese generals had brought back from Korea by the Taiko's orders. This man's name was Risampei. Tradition says that in his own country he had acquired some reputation as a manufacturer of the celebrated "ivory-white," and the story sounds probable, for, had Risampei, like the great majority of Korean keramists, been familiar with the manufacture of pottery and faience only, it is most unlikely that he would have struck out an altogether novel line of his art in Japan. He had worked at Arita during two, or perhaps three, years, when, about 1599, he discovered on the slopes of Idzumiyama (the Mountain of Springs) a white substance that promised to supply the long-felt want. Resembling rather stone than clay, this *shiro-tsuchi* (white clay), as the Japanese commonly called it, had to be broken and pulverised in mills before the potter could employ it. It was in fact the *Petuntsu*, or feldspathic rock, of Chinese keramists.

Risampei's ware was known in the days of first manufacture as Kinko-yaki, Kinko being the name of his native place in Korea. I have said that the decoration of his pieces was limited to designs in blue under the glaze. The fact is that neither Risampei nor any other among the large number of Korean potters, brought to Japan by the Taiko's generals, could impart to their conquerors a knowledge of the methods of applying vitrifiable enamels over the glaze. It may be that the development of this process was checked by a comparatively trifling lack of information. The Japanese, already wonderfully skilful in other branches of technical art, would scarcely have been at a loss how to imitate the enamelled porcelain of China, had they not failed to perceive that, the vitrification of the enamels being effected at a much lower temperature than the baking of the *pâte*, the two operations must be conducted separately. But the Koreans, were they, too, ignorant of this? Among the numerous specimens of old Korean faience and porcelain preserved in Japanese collections, Captain Brinkley has seen only one decorated with coloured enamels over the glaze. This piece is attributed to the end of the sixteenth or beginning of the seventeenth century. It is certainly not less than 250 years old. But, if its existence seems to show that the manner of using vitrifiable enamels was not wholly unknown to the Korean keramists of Risampei's era, its unique character shows equally that such a process was altogether exceptional. Certainly, Risampei was not acquainted with the secret, nor did the potters of Arita learn it until nearly half a century after the Korean discovery of porcelain clay on Mount Idzumi. The honour of making this great addition to the keramic resources of his country is attributed to Higashidori Tokuzayemon. Like Toshiro and Shonzui, he seems to have contemplated a visit to China. With this view, it is said, he went from Arita to Nagasaki, in 1648, and there awaited an opportunity to carry out his purpose. Nagasaki was then a flourishing town of some six or seven and twenty thousand inhabitants. The Portuguese had been expelled eleven years before, but the Dutch had been settled in Deshima since 1641, and from seven to ten of their ships entered the harbour annually. It was with the Chinese junks, however, that Tokuzayemon had to do. These, too, came from time to time; and it so happened that

Tokuzayemon, explaining the purpose of his journey to a junk-master, learned from the latter the very few points which were needed for commencing the new style of decoration. He hastened back to Arita, and made his first essay with tolerable success. His chief idea appears to have been to imitate the Chinese enamelled wares of the Wanlieh period (1573-1619). But, as the attractions of these depended chiefly upon the brilliancy of their enamels, and as the Japanese potters lacked experience principally in this very branch of their art, no very satisfactory results were achieved. Among Tokuzayemon's fellow workmen, however, was one, Kakiyemon, who, fortunately, became impatient of imitative limits, and conceived the idea of adopting a line in better accord with his country's art instincts. The result was a chaste and very beautiful porcelain. Instead of loading his pieces with diapers and archaic designs in red and green enamels, Kakiyemon made the decorations a subordinate feature, and sought, bycareful conceptions, to compensate for what was lost in richness of effect. No one who has examined pieces decorated in this style which he inaugurated, will deny that his success was remarkable. The *pâte* of his ware was fine and pure, giving a clear, bell-like ring when struck. The milk-white glaze, charmingly soft, yet not lacking in brilliancy, formed a ground harmonizing excellently with the ornamentation, which was simple almost to severity. The enamels were clear and rich in tone, but of few colours: a lustreless red, a grass-green, and a lilac-blue constituting nearly the whole palette. Of the decorative subjects, floral medallions were, perhaps, most common; but the dragon, the *howo* (phœnix), the bamboo, the plum, the birds fluttering about a sheaf of corn, and various kinds of diapers were constantly depicted. The characteristics of this ware are not only the sparseness of the decoration, but also its distribution. Instead of being spread over the surface, the designs are confined to a few places, the object apparently being to surround each little picture with as ample a margin as possible.

Of the Kakiyemon type of Imari ware I am able to show you some very choice examples. This figure, from the Redleaf collection of Mr. Wells; this choice, delicately-enamelled and graceful figurine of Ousugumé, which is illustrated in Audsley's great book, and has been attributed by Japanese experts of eminence to Kakiyemon himself, but which Captain Brinkley considers to be of later date; and a series of plates and small bowls. They give a high opinion of the perfection of bare glaze and decoration which the artist potters of Imari had attained in the porcelain destined for their home use. I do not show you the Imari of exportation; the "old Japan ware" of our ancestors of the 18th and early 19th centuries; the "chrysanthemo-pæonian" ware of Jacquemart, the boast of the Dresden Museum still, and the pride of so many palaces and mansions. It is the existing type of the Imari ware of the cheap draper and grocer shop. Its violent decoration of violet, red, and gold was invented to please the European eye; it apparently does so still. It has little artistic value; it was estimable when it was unique. I could never see its beauty or appreciate its value. It is certainly not in the Japanese taste, and I leave it out of serious consideration.

Imari Blue and White Porcelain.

The decoration here described is that known as blue under the glaze. Blue, thus applied, enters into the decoration of all the enamelled porcelain produced in Hizen, with the exception of the wares of Kakiyemon and his imitators. The decoration with vitrifiable enamels was a process subsequent to the stoving of the glazed piece, and was, in fact, added to a vase which, without it, would have been a finished specimen of blue and white, as in this very early but well decorated and characteristic bottle. To vitrify and fix the enamels, another stoving was required. The Japanese were no great admirers of the deep and intense cobalt blue of the Chinese; nevertheless, the earlier Imari potters and artists followed Shonzui in adhering to the Chinese tradition of intensity of colour, and I show you some specimens of old Imari blue and white, which might well be Chinese of the period of Ming or Kien Lang.

Hirado Blue and White Porcelain.

The old Hirado porcelain shows, says Brinkley, the highest degree of perfection and excellence to which the keramist ever attained. The factory at Mikôchi-yama (written Mikawa-uchi-yama, or the "hill between the three rivers"), like that at Okôchi, was taken under special patronage. It appears that one at least of the potters who came to Japan in the train of Hideyoshi's generals settled at Mikôchi, about the year 1595, and inaugurated the manufacture of faience decorated with blue under the glaze.

No specimens of this ware are believed to be now extant. We may presume that it did not deserve preservation. Some twenty years later, the porcelain clay discovered by Risampei came into use at Mikôchi, but the method of applying vitrifiable enamels not being known, the only colour employed for decorative purposes was blue under the glaze. Probably for this reason the industry did not flourish, and the workshops had long been closed when, about the year 1740, Matsura, feudal chief of Hirado, an island off the coast of Hizen, caused them to be re-opened, and placed the workmen under strict supervision, forbidding them to sell or dispose of their productions without special permission. This nobleman appears to have been a very practical connoisseur. He bestowed scarcely less attention on the potteries of his fief than Louis XV. did on those of Sèvres. The pieces turned out were reserved entirely for his own use and that of his friends, or for presentation to the Court of the Tokugawa Regents in Yedo. I visited lately his descendant, Count Matsura, still living at Tokio. He has his private kilns in his garden. I saw the potter at work (and my wife sketched him) making presents for the Tsarewich, as in the olden time, and he favoured me with some pieces subsequently, which I highly value. To the ware potted at Mikôchi from this time (1740) until the period of Tempo (1830) must unquestionably be assigned the first place among the porcelains of Japan. It is called *Hirado-yaki.* The pâte, finer, purer and whiter than that of either *Nabeshima-yaki* or *Imari-yaki,* owed its exceptional qualities entirely to careful manipulation. On the trituration of the clay and its subsequent washing and straining, pains almost unlimited were bestowed, and the preparation of the glazing material was the work of months. Examined attentively, the *pâte* is found to be virtually free from the dark gritty particles so common in Imari ware, and the granulations in the surface of the glaze, invisible to the naked eye, are not more marked than in the best Chinese porcelain. It is not, however, till we consider the decoration that the incomparable beauties of this *Hirado-yaki* become fully apparent. With rare exceptions blue is the only colour employed. It is not the intense, fathomless colour of the old Chinese keramists, nor yet is it the light, bodiless blue of the Nabeshima ware. It is a colour between the two, exquisitely soft and clear, and harmonising perfectly with the milk-white, velvet-like glaze in which it seems to float. Of the execution of the designs it is impossible to speak too highly. Nothing approaching them can be found in the whole range of Chinese porcelains. One is puzzled to conceive, in the first place, how etching so wonderfully fine, and outlines of such detailed accuracy, can have been transferred to a surface of baked clay; and, in the second, how every process of glazing and stoving can have been effected with sufficient skill to preserve these delicate pictures. There are few subjects which the artists of Mikochi did not depict upon their pieces, and fewer still in which they fell short of marked success. No great number of many really choice specimens of *Hirado-yaki* have yet found their way westward. Only within the last few years did the passion for blue-and-white, suddenly developed in Europe, induce the Japanese virtuosi to place this ware upon the market, and the supply, always very limited, did not last long enough to familiarise American and European collectors with the merits of Japan's best porcelain.

The pure white porcelain of old Hirado is remarkable for its milky glaze; the modern commercial imitators are less perfect in material, have a greenish tint in the glaze, and are less perfect in the potting. Besides blue and white, the most characteristic colour used is brown. Of these chromatic Hirado pieces you have before you some noble pieces. You will notice the large covered bowl which has evidently served as a model for our old Bow and Plymouth ware, with shells and seaweed in relief. The figures, birds, flowers, and delicate reliefs of Hirado gave many hints to Dresden. Of these original models, I have placed some exquisite and important specimens, selected out of many in my possession, on the table.

The Nabeshima ware, made at the Okôchi-yama kilns, under the patronage of Nabeshima, feudal chief of Hizen, are not less remarkable for their perfection of blue and white decoration and of paste than those of Hirado. They have generally, also, a characteristic combination of red introduced. The Nabeshima potters, as a rule, did not use marks, and never copied Chinese marks except on pieces which were obvious reproductions of Chinese originals. The reason of this is easily understood when we remember that the productions of the Okôchi factories were destined solely for the House of Nabeshima. Okôchi, in fact, was a private kiln. There was no occasion to mark porcelains manufactured there as though they were intended for general sale. With the rare exception of an occasional ideograph,

Nabeshima-yaki may be said to be without marks or seals of any description. Nabeshima ware was not a mercantile product, and seldom comes now into the market. I show you a few specimens of it, but I have seen few specimens of the original ware for sale over in Japan.

Satsuma Faience.

Whatever title to keramic celebrity Japan may found upon her porcelain, it is probably for her pottery that she will be longest spoken of. For while, says Brinkley, her porcelain manufacturers—those of Hirado excepted—were always more or less subservient to the fashions of Chinese originals, her workers in pottery and faience gave untrammeled play to their native genius, and, both in shapes and styles of decoration, produced pieces of the greatest beauty and quaintness. Among all the faïences of Japan, western amateurs have agreed to assign the first place to the well-known Satsuma-yaki. One may safely say, says Brinkley, that no European and American collection is deemed complete unless it contains a piece of the ware; and to this I am disposed to add—though few will be disposed to believe it—that Western collectors rarely possess a really representative specimen. It may not be denied that pottery of a brilliantly decorative and at the same time artistic, nature has been exported in considerable quantities to Europe and America during the past ten years, under the name of old Satsuma, but there need be no hesitation in asserting that in many and most essential respects, this showy ware differs completely from the beautiful faience so highly prized by Japanese connoisseurs. If it be admitted that first-class specimens of ancient Chinese celadon bear some comparison with the jade which they were designed to imitate, there will be no risk of hyperbole in asserting that the satsuma ware of bygone times can scarcely at first sight be distinguished from ivory.

In 1598 the celebrated Shimazu Yoshihiro, chieftain of Satsuma, returning from the invasion of Korea, brought with him a large number of workmen, some five score it is said, of whom seventeeen were skilled potters. They were settled at first in three villages, Kushikino, Tchiku, and Sanno-gawa; but, subsequently, a few of the most skilled of them were removed to Chôsa, in the neighbouring province of Osumi, where their patron, Yoshihiro, had one of his castles. Here, ware of various sorts was produced, some copied directly from Korean models, some covered with glaze of various colours—green, yellow, or black—and some of a flambé description. The paste was fine, and well manipulated, and of a greyish-red colour; but the chief beauty of the ware, or, rather, of the parti-coloured and flambé varieties, was the glaze, of which two, three, and sometimes four coats were applied, as in the bowl on the table, until effects of considerable richness and diversity were obtained. A potter, called Saburohei, was especially renowned in this matter of glaze. His pieces bear no mark, but connoisseurs profess ability to distinguish them at once, by their excellence of shape and lustrous surface. Here is a specimen attributed to Saburohei, and here a much more modern reproduction, but still one of great beauty and richness of glaze.

About the year 1670, Mitsuhisa, then chief of Sasshiu, caused a kiln to be set up in the grounds of his own castle, and the workmen employed there were familiar with the use of vitrifiable enamels. Iyemitsu, third regent of the Tokugawa dynasty, had encouraged the already growing taste for highly-decorated ware, and his influence was felt at all the centres of keramic industry in Japan. The Prince of Sasshiu, having established a factory, invited thither the painter Tangen, pupil of the renowned Tanyu and commissioned him either to paint faience himself, or to furnish the workmen with designs. The outcome of this factory was necessarily small, the pieces being destined entirely for private use or for presents. But that enamelled faience was produced there, and that beautiful specimens, known to this day as "Satsuma-Tangen," from the name of the artist engaged in their decoration, are amongst the treasures of Japanese collectors, there is no valid reason to doubt. The point to be observed is, that this fashion of decoration did not, at that time, extend to any other factory in the province. Thus, when the successors of Prince Mitsuhisa ceased to patronise the art, and when the private kiln established by the noblemen was closed, a considerable period elapsed before the potters of Satsuma thought of studying processes which no longer received the encouragement of the lords of the district. At the end of the 18th century, however, Mari Akihira (afterwards called Yeiô), Chief of Sasshiu, took the factory at Satsuma under his protection. It was at his instance that the two workmen, Kin and Kuw-abara, visited Kyôtô; and it is to his patronage that we

owe the renaissance, afterwards erroneously described as the origin of Satsuma enamelled faïence.

The distinguishing feature of the specimens produced in the time of Yeiô, as well as in the early days of the manufactures, was the fineness of the *pâte*. It was as close-grained as pipe-clay, and almost as hard as porcelain biscuit. The Satsuma potter confined himself strictly to diapers, floral subjects, landscapes, and a few conventionalities, such as the Howo, the Shishi (mythical lion), the Dragon and the Kirin (unicorn).

Although the faience of Satsuma is known to Western collectors chiefly for the sake of its enamelled pieces, its monochrome and flambé glazes also deserve mention. Of the former, yellow and black are the most remarkable, but both are exceedingly rare. Another monochrome glaze, which may almost be called a speciality of the Satsuma potters, is olive green. This colour, however, is seldom employed alone, being generally associated with a peculiar dark mustard yellow, or a chocolate brown. Such glazes as these are, for the most part, confined to tea jars, incense boxes, and other utensils for use at Cha-no-Yu ceremonials. Neither is the *pâte* of pieces thus decorated made of the well-known white earth, but of an exceedingly fine iron-red pipe-clay, which the amateur easily learns to recognize after he has seen one or two specimens. Another infallible guide in identifying a Satsuma tea jar (chatsubo) is the ito-giri, a mark left on the bottom by the thread with which the potter used to sever the piece from the clay out of which it was modelled. This mark is found upon all carefully manufactured Japanese tea jars; but since the Korean workmen, who settled in Satsuma, turned the throwing-wheel with the left foot, while potters at other factories turned it with the right, it will be readily understood that the spiral of the Satsuma thread-mark is from left to right, and that of other factories from right to left. Pure white faience, sometimes cleverly moulded or reticulated, was a favourite production of the ancient Satsuma potters.

In illustration of the varieties thus succinctly described by Brinkley, let me show now specimens—(1) of the flambé ware of Satsuma, this tall jar of tiger-skin glaze; (2) specimens, of which I have many, of the white, or, as the American connoisseurs call it, from its subtle undertints, the "mushroom," or undecorated crackle, of which the rarest are this bottle with white raised hawthorn, this figure of the boy and fan, and this okimono of Fusyama, with clouds at its base, and the figure of Fukurokuju; (3) the rare specimens of black satsuma, of yellow satsuma, and of satsuma-Tangen, decorated with freehand drawing; (4) this Chinese boy (Karako) with brocaded robes; and (5) an unrivalled example of the ivory ware in this very fine figure of Hotei. I do not need to say a word about any of these specimens. They speak for themselves. In acquiring the collections of Maizan, and the choice specimens of Wakai and Hayashi Sohichi, I was able, at a stroke, to secure a series which I had never hoped to obtain. For, during the whole of my stay in Japan, in private and public collections, and in all the collections which I have seen in Europe, fine Satsuma of the older dates is the rarest and least attainable, while spurious imitations are the most abundant and disfiguring features. But of some thousands of pieces of so-called Satsuma offered me elsewhere, and at other times, I have hardly ever found one that was both genuine and of any art value.

Faience of Kyôtô and Environs.—Specimens by Nomura Ninsei.

With Nomura Seisuke (called also Seiyemon and Sebei) the real history of the famous Kyôtô faience commences. There is no name more renowned in the catalogue of Japanese Keramists. His native place was a village near the shrine of Ninwaji (pronounced Ninnaji) in the environs of Kyôtô, and by combining the initial syllables of this word with that of his name (Seisuke) there was obtained the term "Ninsei," by which the man and his works are known to posterity.

It will be remembered that the methods of decoration with vitrifiable enamels was acquired by Tokuzayemon, of Arita, in 1648. Naturally a considerable quantity of the new ware found its way to the capital, where it excited at once the admiration and envy of the leading keramists. But for a time the possibility of imitating it does not seem to have been conceived, since the secret was guarded at the Hizen factories by a series of the most rigorous enactments. It happened, however, that, between the years 1650 and 1654, a certain Aoyama Koyemon, acting as agent for the sale of the new porcelain, associated himself with one Kuhei, a faïence vendor of Kyôtô, and was persuaded by the latter, who seems to have been gifted with no small amount of tact and craft, to disclose the

methods which had won for Arita so valuable a monopoly. The unfortunate Koyemon's indiscretion is said to have cost him his life, but the precious recipe remained in Kuhei's possession, and subsequently passed into the hands of Nomura Ninsei. We may, therefore, with very little risk of inaccuracy, ascribe the first manufacture of enamelled faience in Japan to the year 1653.

Not having made keramics his profession, Ninsei had no fixed workship. His first productions were potted in the neighbourhood of the temple of Seikan, and at a kiln called Otowa, both of which are in the district of Omuro. Hence the origin of the term *Omuro-yaki*, by which these pieces are generally known. Subsequently he worked at the factories of Awata, Iwakura, and Mizoro, not only practising but imparting the secrets he had acquired. All these places are in or near Kyôto.

If Ninsei's title to fame rested solely upon the fact that he was the originator of enamelled faience, he would deserve to be remembered. For, though he did not invent these processes, his manner of employing them marked an epoch in the history of his country's keramics. Under his inspiration the wares of Kyoto assumed a new character. He was the first to shake himself free from alien influences, whether Chinese or Korean, and to adopt the "natural style" now universally regarded as representative of Japan.

In Ninsei's hands, the faience of Kyôtô became an object of rare beauty. Not only was the *pâte* of his pieces close and hard, but the crackle of the buff, or cream-coloured glaze, was almost as regular as the spider's web. Only the most painstaking manipulation of materials and management of temperature in stoving could have accomplished such results. In later and less conscientious times, the nature of the crackle changed so perceptibly, that this one point affords a trustworthy criterion of old and fine ware. Ninsei's crackle was nearly circular. The surface of choice specimens of his handiwork conveys the impression of being covered with very fine netting, rather than with a tracery of interesting lines. Its appearance is aptly described by the Chinese term "fish-roe crackle." Working, as he did, at different places, varieties are found in the *pâte* of his pieces. The most common is a hard, close-grained clay, verging upon brick-red in colour, and perfectly free from foreign particles. Sometimes the colour changes to a yellowish grey, and the texture becomes nearly as fine as that of pipe-clay. His monochrome glazes are less remarkable than his crackle. First among them must be placed a metallic black, run over a grass-green in such a way that the latter shows just sufficiently to correct any sombreness of effect. On the surface of this glaze, or else in reserved medallions of cream-like crackle, are painted diapers, and chaste floral designs in gold, silver, red, and coloured enamels. Another glaze invented by him, and imitated successfully by the chief experts among his successors, is a pearl-white, through which a pink blush seems to spread. In golden brown, chocolate, and buff he also produced charming tints, and his skill as a modeller was scarcely less than his mastery of mechanical details. As a rule he marked his pieces with the two ideographs Ninsei engraved in the paste.

Genuine specimens of his ware are very scarce. They do exist, and find their way into the market from time to time, but their high value in Japan—as much as two or three hundred dollars, are readily paid for a small bowl of the best description—effectually keeps them out of Western collections. If it were required to indicate tests of easy application for determining the claims of a piece attributed to Ninsei, we should name, first the *pâte*, which ought to be very hard, and of brick-red or yellowish gray colour; and, secondly, the crackle, which should be uniform and of circular shape. On Ninsei's great contemporary, the painter Tanyu, it cannot be denied that he deserved a considerable part of the fame which fell to his lot. The famous artist and the great keramist appear to have been fast friends. It is related that they took an equal interest in each other's art, and that many of the pieces manufactured by Ninsei bore designs from the brush of Tanyû or his pupil Yeishin. These designs were largely imitated at the Kyôtô factories, and the popularity of pieces thus decorated was shared by specimens copied from Chinese ware ornamented with fishes from the brush of a Chinese artist, Bokkei, and hence called *Bokkei-bachi*. In fact, public taste turned completely from the sober and severe style of the Seto potters. Decorated faience became the rage, and in some quarters of Kyôtô every second house had its little workshop and kiln. I would name to you, as peculiarly fine and authentic specimens of Ninsei's work before you, the crab, the letter-press shaped as a kakemono, the tall bottle decorated with flowers,

and some of the smaller pieces which I put before, out of many which have at various times been sent me from Japan.

Awata Faience.

Under Ninsei's influence, however, the industry attained such dimensions, that particular kilns began to be spoken of. Amongst these, the most important is that of Awata. It was established about the year 1620 by an artist, called Kuzayemon, of whose origin and early history we have no record. At first, his productions attracted little attention, but, by and by, he began to copy Ninsei's methods, decorating his pieces with black and blue pigments, and, ultimately, with coloured enamels. Ninsei himself visited the Awata factory, and manufactured many good specimens there, although the materials which the district afforded were not of the choicest. The *pâte*, indeed, of the Awata-yaki was close, pure, and hard in those early days; but its glaze was not pleasing, being generally of a greyish white, semi-translucid, and lacking the soft yet rich tone which is justly so much admdier in fine specimens of Japanese faïence. The crackle was uniform, and tolerably small, but frequently its too palpable edges imparted to the whole surface a slightly crude aspect. Probably, for this reason, the Awata potters soon fell into the habit of decorating their pieces more profusely than those of other factories. Early in the 18th century, however, a workman whose artist-name was Kinkôzan, effected signal improvements in the Awata ware. Under his treatment the glaze lost its imperfections, and assumed a creamy lustrous tone, which formed a beautiful ground for the enamels. Among the latter the two principal were grass-green and ultra-marine. Red was also used, and gold is found almost invariably, its rich sheen harmonising excellently with the soft buff colour of the glaze. Silver, purple, and yellow are rare. Some specimens of *Awata-yaki* are marked with the ideographs, *Awa-ta*; others are marked *Kinkô-zan*; but the majority are not thus distinguished. In determining the age of a piece of this faïence, three rules, equally applicable to all the wares of Kyôtô, may be laid down; first, the *pâte* of choice old specimens is close and hard; secondly, the glaze is lustrous, and the crackle fine and uniform; thirdly, the enamels are clear, brilliant, and carefully applied. It may generally be assumed that the degree in which these qualities are present varies directly as the age of a piece, always remembering, however, that when judging Awata faïence, an exception must be made in respect of specimens manufactured before the time of Kinkô-zan (*i.e.*, during the 17th century), for these, while fully satisfying the first and third of the above conditions, usually fail with regard to the second.

Kenzan Ware (Faience).

The history of the keramics of Kyôtô is a record of individuals, not factories. Ninsei's figure overshadows all the rest, and next to him, at no great distance in some respects, comes Ogata Sansei, commonly called Kenzan, Ogata was born at Narutaki-mura, in the suburbs of Kyôtô, in the year 1660; that is to say, just at the time when the methods introduced by Ninsei and Wanjin had fairly won their way to public favour. He was the second son of Ogata Soken, and his younger brother was the celebrated painter Korin. Sansei, who appears to have been called also Shinsei and Shinsaburo, was himself a painter of considerable promise, but his proclivities, fortunately, lay in the direction of keramics. After he had studied literature and poesy under the well-remembered Hirosawa Nagayoshi, and the mysteries of *Cha-no-Yu* under Zuiriu Sosa, whom the men of the next generation elevated into a semi-divinity, under the title of Nichiren Sosa, he spent a short time in the practice of his father's favourite art, and his pictures are said to have given earnest of great talent. That he preferred to devote his brush to the ornamentation of faïence was partly, perhaps, because the designs furnished for that purpose by Tanyu and Yeishin had attracted so much attention, and partly because his brother Korin, in whom he must have recognised a greater artist than himself, had already developed a taste for lacquer decoration. At first he appears to have applied himself diligently to the study of technical processes, taking for his instructors the potters of Raku, Seto, and Zeze. Very soon, however, he developed an original style, of which the chief characterists are great boldness, combined with a very skilful disposition of tints, both in the execution of designs and in surface decoration. Kenzan is, in fact, a perfect representative of the genuine Japanese school, which requires that results, however elaborate, shall convey no idea of detailed effort, and enforces strict obedience to the natural principle of limited impressions. A branch of plum blossoms, a tuft of feathery

reeds and bending grasses, a family of sparrows clustering amid the foliage of a bamboo, or the blue crest of a mountain peeping through a haze of golden clouds—such things as these can be comprehended at a single glance, and are, therefore, legitimate subjects for representation in the circumscribed field which the artist has at his disposal. Kenzan thoroughly understood this. His designs are often exceedingly artistic for all their simplicity, and the landscapes depicted on some of his smaller pieces embody most graceful conceptions. He preferred *Shibu-ye* and *Ai-ye*—designs in black, russet-brown, and blue—to *Kin-ye*—designs in coloured enamels and gold. But in all three varieties of decoration he showed himself equally a master. His best pieces were potted at Awata, and neither their *pâte* nor their glaze is distinguishable from that of the ordinary *Awata-yaki*; the style, however, cannot possibly be mistaken. A further guide is the cachet. Kenzan marked all his pieces with his name, "Kenzan." Sometimes he used clay from other localities, especially that ftom Shigaraki (*vide* "Shigaraki-yaki), which produced a coarse, gritty *pâte*, far inferior to the *Awata-yaki*, but well adapted to the exceptionally bold outline-sketches which, with true artistic instinct, he invariably employed in the ornamentation of these rougher specimens. At a late period of his career we find him working at Iriya, in Yedo (now Tôkyô), but the materials procurable in the neighbourhood of the eastern capital were of such inferior quality, that even Kenzan could produce nothing satisfactory with them. Urged rather by love for his craft than desire of gain, he never attempted to manufacture large quantities of faïence, so that genuine specimens of his work are exceedingly rare, and proportionately valued. His style was, however, copied with considerable fidelity and success by his son and grandson, whose pieces, marked with the same cachet, "Kenzan," only differ from those of Ogata himself in being slightly inferior both in *technique* and artistic qualities.

Here are some characteristic specimens of the different styles of Kenzan, all of them marked with his cachet; plateaux-coupés and perfume-boxes, some of them from designs by his brother, Korin, and therefore having a double interest. They are so characteristic in their bold and sketchy impressionism that they form a school by themselves, and once seen are easily recognised.

EIRAKU WARE.

I show you, without entering into details, some remarkable specimens of the work of Mokubei, a great potter, whose history I reserve for another occasion. The processes which Mokubei had originated were, says Brinkley, extended and perfected by Zengoro-Hozen, commonly called Eiraku. This man's speciality was the manufacture of urns (*furo*) for the *Chajin*. His factory was at Nara, and he enjoyed the patronage of the renowned dilettanti Shukô and Jô-ô. After his death (1558), his son, Nishimura Sôzen, moved to Sakai, in Senshû; and Sozen's son, of the same name, transferred his residence, in 1594, to Shim-kyô-roku-jô, in Kyôtô, from whence one more move to Anraku-koji brought the family to the house it occupied until nearly the middle of the present century. The representative of the eleventh generation was Zengoro-Hozen. At first, content to follow the route trodden by his ancestors, he confined himself to the production of unglazed urns for the use of the tea clubs. Even in this work the remarkable dexterity with which he blended *pâtes* of different colours gave earnest of greater achievements in other branches of the keramic art. This promise was soon fulfilled. Practising porcelain manufacture as a species of pastime in the intervals of his regular trade, he ultimately developed such skill that his celadons and pieces, decorated with blue under the glaze, attracted wide attention. To these he soon added admirable imitations of the old Cochin-Chinese faïences. The conditions of the time were especially favourable. Long continued peace had filled the coffers o[f] the nobles, and induced those luxurious ha[bits] of life among which art products find th[e] best market. The Court at Yedo, preside[d] over by Iyenari, eleventh prince of the Toku-gawa dynasty, set an example of brilliant extravagance, to which the feudal princes were nothing loth to conform, while the now well-established custom of sending to the Shogun yearly presents of pottery and porcelain from the various districts, had engendered a wholesome rivalry among the provincial factories. Before long, Zengoro's fame attracted the attention of Harunori, Lord of Kish[iu]. He invited the potter (A.D. 1827) to his pr[o]vince, and there set up for him, within the [pr]ecints of the castle park, a kiln, at which w[a]s produced the celebrated *Oniwa-yaki*, or *E[i]raku* ware, as it is also called, from the s[ta]mp it bears. It was an imitation of the [C]hinese faïence, but, in purity of colour, it [sc]arcely

equalled its original. Like Luca della Robbia, Zenguro made the composition and application of glazes an especial study. We search the works of his successors and predecessors in vain for examples of parallel perfection in this branch of keramics. His Aubergine porcelain, and the rich combinations of turquoise blue, purple, and yellow shown in the glazes of his faïence, amply justify the immense popularity attained by the Yeiraku ware. A prominent place among his achievements belongs to his *Kinrande* or *Akaji:kinga*, which bears the stamp *Eiraku*. The idea of this porcelain was derived from the much-valued Chinese "rouge vif" of the *Yung-lo* period (1403-25), and the Japanese potter succeeded in producing a colour little inferior to that of the original. In fact, his coral-red glaze, lustrous and, at the same time, exquisitely soft, with its wealth of golden decoration and reserved medallions in brilliant cobalt, must be classed among the keramic masterpieces, not of Japan alone, but of the whole world. These terms *Kinrande* (scarlet and gold brocade pattern) and *Akaji: kinga* (golden designs on a red ground), are descriptive. The stamp *Eiraku* was suggested by the Japanese pronunciation of the Chinese period-name, *Yung-lo.* The Chief of Kishu also bestowed upon Zengoro another seal, inscribed with the ideographs, *Ka hin Shirui.* This seal Zengoro appears to have used to mark his choicest pieces only; a distinction which accords with the material of which the two seals were made, that bearing the characters of *Eiraku* being of silver, and that bearing the characters *Kahin-Shiriu* of gold. rom the time of his visit to Kishu the potter's e rapidly augmented. It became the fashion h the magnates of the western capital to ve him orders, and their amusement to test is skill by asking him to copy *chef d'œuvre* of Chinese, Korean, and even Dutch manufacture, which had been handed down in their families for generations. Zengoro's success in these trials of skill is said to have been remarkable. It is recorded that a tea-urn, secretly borrowed by a court noble called Takatsukasa from the custodians of the Kono-e heirlooms, was so perfectly imitated at the Eiraku workshop, that the original and the imitatin were not distinguishable. This feat procurd for Zengoro another seal bearing the inscripbn *Tokin-ken* (the weighty potter); a mark wich is not found upon his wares. From Prince risugawa he also received a document conferr-g the title of *Ito-seimei* (the world-renowné keramist). Opulent and respected, Zengoro might now have passed the remainder of his days in repose and comfort. But his heart was in his art. Like Bernard Palissy, the successful production of a new glaze was to him almost a matter of life and death. He had mastered the processes required to produce the purple, yellow, turquoise, and green faïence of Cochin China, the blue and white, coral-red, and enamelled porcelains of China. Two things only he could not copy—the stanniferous glaze of the Delft faïence, and the transmutation glazes of the Po-yang lake. To the investigation of these he employed himself diligently, gradually spending upon fruitless experiments the money he had accumulated by his previous works.

I show you specimens of the various styles of Zingoro; his brilliant coral and gold, his red-violet, his various and polychromatic kogas. You will recognise the perfection of the technique, and the purity and intensity of the colour.

Kutani Ware.

After the wares of Hizen, Kyôtô, and Satsuma, there is none better known, outside Japan, than the *Kutani-yaki*. The origin of the factory is attributed to Mayeda Toshiharu, lord of Taichoji, in the province of Kaga, who who caused a kiln to be built at the village of Kutani, and placed it under the direction of his vassal, Tamura Gonzayemon. The exact date of this event is not known, but it certainly lies between the years 1635 and 1660. It does not appear that any keramic industry had existed in Kaga before that time—a condition which probably resulted from the comparatively isolated position of the province, lying, as it does, on the extreme west of Japan, and being separated by a lofty range of mountains from Kyôtô, the centre of luxury and art-patronage. The productions of the new kiln were after the fashion of the old Seto ware; that is to say, tea-jars and water-vessels of dark clay, covered with a light chocolate glaze. In 1665, however, Toshiharu's son, Toshiaki, anxious to develop the so far unpromising enterprise which his father had inaugurated, sent one Goto Saijiro to Hizen, for the purpose of acquiring the methods of porcelain manufacture. On his return, the nature of the *Kutani-yaki* underwent a complete change.

Yet there is nothing at all perplexing or doubtful about the history of the Kutani factories. During the 17th and early part of the 18th century, the wares produced there were of two sorts. The first, and more

characteristic, was the *Ao-Kutani*, so called from a deep green (*ao*) glaze, of great brilliancy and beauty, which was largely used in its decoration. Associated with this glaze were others, not less lustrous and full-toned, yellow, purple, and sometimes a soft Prussian blue. These glazes were laid on so as to form diapers, scrolls, and floral designs; or they were simply run over designs traced in black on the biscuit. That the decoration must be regarded as, and was, indeed, confessed to be, an imitation of that attributed to the potters of Cochin China in their *Kôchi-yaki*. The second class of ware was decorated somewhat after the Arita fashion, with this principal difference, that the Kutani potters never, so far as we know, employed blue under the glaze in conjunction with enamels. Their chief colours were green and red, supplemented by purple, yellow, blue (enamel), and gold. Red was a speciality. They produced a peculiarly soft, subdued, full-bodied colour, varying from a rich Indian-red to a russet-brown. For designs, the early potters had recourse to a well-known artist, Kuzumi Morikage, of the Kano school, who loved to depict miniature landscapes, flowers ruffled by the breeze, sparrows perched among plum-branches, and other glimpses of nature in her simplest garb. We never find anything resembling that wealth of brilliant blossoms and massing of bold colours by which the porcelain of Arita was distinguished. The keramists of Kaga were always faithful to the fashions inaugurated by Morikage. On many of their best productions the decoration is of a purely formal character, diapers, scrolls, and medallions, containing conventional symbols. The only figure-subjects met with are the Chinese *Karako*, or children at play. As with the faïence of Satsuma, so with the ware of Kutani, the amateur may be quite sure that specimens decorated with peacocks, groups of chrysanthemums and peonies, figures of wrinkled saints or brightly draped ladies, cocks upon drums, and so forth, belong to the manufactures of modern times.

So far we have spoken of the style of decoration only. The *pâte* remains to be considered. Here a difficulty presents itself. The potters of Kutani originally took their clay from a hill near the village of Azayatsu. It was not porcelain earth; it was not even capable of being manufactured into good pottery. Thus we find that some of the oldest pieces of this ware are technically very faulty. But these pieces do not belong to either of the classes mentioned above. The incongruity of applying lustrous glazes or rich enamels to a radically defective *pâte* was recognised at once, and the Kutani artists, baffled by the refractory nature of their local materials, imported good clay from Hizen, or any other convenient place. Sometimes they used this imported clay only; sometimes they eked it out by an admixture of earth procurable on the spot; sometimes they even went so far as to apply their own decorative processes and marks to biscuit manufactured elsewhere. There resulted a considerable source of perplexity for the amateur. Among specimens of the old *Ao-Kutani* he will find stone-ware and porcelain; while, on the other hand, pieces decorated after the fashions inaugurated by Kuzumi Morikage are, with very rare exceptions, excellent porcelain. We have seen pieces of *Kutani-yaki*, dating as far back as the beginning of the eighteenth century, which would bear comparison with the best Hizen egg-shell. It has to be confessed, therefore, that among all the wares of Japan, the *Kutani-yaki* alone offers a *pâte* as likely to mislead as to instruct. This is especially true of blue and white specimens. We have said that, so far as we know, or have been able to ascertain from Japanese experts, *blue sous couverte* is never found upon old Kutani ware in conjunction with enamelled decoration. But pieces decorated with blue only, though rare, are occasionally met with. In these, the connoiseur's only guides will generally be the nature of the glaze and the tone of the blue. The latter lacks the depth and richness of the best Hizen blues, and is equally removed from the delica purity of the Hirado colour; it is, in fact, inferior, somewhat impure, pigment. Thi however, is obviously an uncertain criterion the glaze is more trustworthy. It shows a peculiar waxy softness, which generally suffices to establish a distinction. But, in truth, specimens of blue and white kutani are so very exceptional, that we need scarcely dwell upon their characteristics. In the case of polychrome pieces, the richness and lustre of the enamels, their full, clear colours, and the severity of the decorative style, constitute features easily identifiable. Above all, the beauty of the glaze is incomparable. In choice specimens, its tone almost equals that of the celebrated ivory-white of China.

You can judge, from the specimens on the table, the justice of Captain Brinkley's eulogy. The tall-necked bottle and the censer, in its

pierced silver cover, are perfectly typical specimens of the most characteristic styles; while this white jar, with Chinese figures in coloured enamel, shows how close they came to the Chinese originals in that style. I bought it in China, and but for its seal, it would pass for Ming ware.

KISHU WARE.—ONIWA-YAKI, OR KAIRAKU-YEN-YAKI.

A little more than half a mile westward of Wakayama, in the province of Kishû, stood formerly the country residence of the family whose representatives governed the district. Within the park of this Nishihama, at the beginning of the present century, Tokugawa Harunori, then head of the family, caused a private kiln to be built for the manufacture of porcelain decorated with blue under the glaze. We have seen that the porcelain industry, as distinguished from that of pottery and faïence, received a notable impulse in the opening years of the 19th century. The Nishihama factory is an example of this development. Very little is known of its first productions. They were completely lost sight of when, in 1827, Harunori, after one of his periodical visits to Kyôtô, brought back with him the already renowned keramist, Zengoro Hozen. The character of the Kishû-yaki immediately underwent a complete change. Zengoro had made his name by imitating the brilliant glazes of Cochin-China, and to this species of work he applied himself at Harunori's factory. The outcome of the kiln was thenceforth known as *O-niwa-yaki* (ware of the honourable park) or *Kairaku-yen-ki* (ware of the park of ease and fellowship). The *pâte*, sometimes white, sometimes reddish gray, was very fine, varying from porcelain to faïence, but being for the most part a hard stoneware. The glazes were remarkably rich and beautiful: purple, green, turquoise, yellow and white. They were employed in various ways. Perhaps the most common was a purple ground covered with scroll-work in relief, portions of the scroll being filled with turquoise blue. In other and more excellent pieces we find a rich green mould marbled with purple, or decorated with medallions in yellow, purple, white and blue. Glazes showing greater richness, lustre, and purity colour were never produced by any Japanese potter. Harunori loaded Zengoro with favours, and bestowed on him three seals: two of silver, bearing the inscriptions *Kairakuyen* and *Eiraku*, and one of gold, inscribed *Kahin Shiriu*. Japanese antiquaries say that the term *Kahin Shiriu* (branch of *Kahin*) has reference to the earliest pottery of China, which, according to them, was manufactured by an artist called Chun, at the kiln of Kahin (Chinese *Hopin*), about 4,000 years ago. This point is involved in obscurity. Eiraku, as we have already explained, is the Japanese pronunciation of the Chinese period *Yung-lo* (1403-1425), during which was first produced the celebrated "rouge vif," with decorations in gold. Zengoro never allowed any specimen to leave his hands bearing the stamp *Kahin Shiriu* unless he was thoroughly satisfied with the success of his work. Sometimes he added the mark *Eiraku*, and in many cases his imitations of the Chinese turquoise-blues and purples are stamped simply "*Kairaku-yen*. He generally worked to order, and it is said to have been his habit to manufacture from five to ten specimens of any piece which he had undertaken to produce. Of these, the best was chosen, and the remainder were destroyed in the presence of the person who had ordered them. He appears to have remained some eight or nine years in Kishu, and after his return to Kyôtô, the Nishihama factory was placed under the direction of another workman from the western capital, by name Yoshehei. It would appear, however, that Zengoro's glazes were not to be compassed by any other expert. The Kairaku ware gradually lost its high character, and on Harunori's death, in 1844, the manufacture came to an end.

This Kishiu bottle, is, I think you will say, quite equal to the finest Chinese ware in colouring and glaze, and is a very good example, together with others of the products of the best periods of the Kishiu kiln. I bought it in Kioto, from a collector who prized it as his best piece, but who had another somewhat larger, and was willing to part with this.

IMBE, OR BIZEN (STONEWARE).

The *Imbe* ware was produced at a place of the same name, in the province of Bizen. Pottery was made, no doubt, in this district at a very early date, but does not seem to have attracted any attention before the end of the 15th century. Even then, too, it was of the coarsest description, its gritty red *pâte* and unglazed surface fitting it for the manufacture of only the commonest utensils. From Hideyoshi's time (1580), a considerable improvement became visible. The clay was manipulated with greater care, and some of the specimens are compared by connoisseurs to

the Chinese boccaro, which they were, no doubt, intended to imitate. The most valued pieces of this, *Kok-bizen* (old bizen), are those stamped with the shape of a new moon (*Mikazuki*), a waning moon (*Kayezuki*), or the characters *Kokubei;* while another slightly inferior variety bears the delineation of a cherry blossom. Originally, the terms *Bizen-yaki* and *Imbe-yaki* were interchangeable, but by degrees the former came to be applied to the unglazed, the latter, to the glazed specimens; while a third term, *Hidasuki*, was introduced to describe a variety in which the surface is marbled by irregular patches or lines of red. A tolerable idea of the pottery's qualifications, as well as of the Tea Clubs' proclivities, may be formed from the fact, that this marbled effect is obtained by tying straw ropes round the pieces before placing it in the oven; and that an approved specimen of the rough unglazed result—which resembles nothing more than a half-baked brick—easily finds a purchaser to-day at from 50 to 100 dollars.

This criticism applies only to the Bizen pottery of old times. Towards the close of the 17th century, the character of the ware underwent marked improvement. A slate-coloured or a brown *pâte*, fine as pipe-clay and almost as hard as porcelain, was used to model figures of deities, genii, birds, fishes, aud mythical animals. It is scarcely possible to speak in too high terms of the plastic ability thenceforth developed by the Bizen potters. Their best efforts are admirably faithful, and will bear comparison with similar work produced in any country and at any age. A little later they used a red clay giving a *pâte* scarcely less fine and hard than of the *Ao-Bizen*, as the former variety is called. The glaze applied to this red *pâte* is peculiar to Bizen. Its colour and metallic sheen give it exactly the appearance of the beautiful *Sentoku*, or golden bronze. Those who have seen choice specimens of this middle period Bezen stoneware cannot hesitate to class it among the very highest achievements of Japanese art. As for the Bizen pottery of our own time, we need only say that it has shared the general degeneracy of its fellows. The red-clay figures of obese deities and unreal monsters that now-a-days stand in every *bric-à-brac* shop, may possess some attraction borrowed from the traditions they recall, but cannot be counted types of either cunning craft or praiseworthy art.

The finest old Bizen, in brown salt glaze, and in the still rarer grey and white varieties, are quite worthy of the highest eulogy. This little okimono in wood ware, and this group of birds, this cock, and brick, I have selected as examples. The white Bizen is rarest of all. The bird on a stump and the hotsei on the table are specimens of which I know no equals. It is hardly to be found now in Japan. I was asked an exorbitant price for a broken piece—an owl in Osaka—and I hesitated, but when I made up my mind to have it, it was gone to a private collector. There is a modern imitation of it, and of the grey Bizen, which is known by the softness of its added glaze, and by its dull sound, and imperfectly baked vase. The old Bizen was left for many days, and even weeks, it is said, in the kiln, so that the glaze is thoroughly incorporated into the vase—burnt into it as one body — and it has a hard, metallic ring. There is no more thoroughly characteristic ware of old Japan.

Higo Ware (called also Yatsushiro or Udo Ware). (Faience.)

The principal province of Kiushiu is Higo, which lies to the south of Hizen. The feudal chief of this province, at the end of the sixteenth century, was the renowned warrior, Kato Kiyomasa, who led the expedition of 159z to Korea. Returning in 1598, he brought with him a Korean potter, who had previously exercised his trade at Pusan. This man's name was Sonkai (Japanese pronunciation), but on being enrolled among the vassals of Kato Kiyomasa he became Uyeno Kizo. Keramic factories had existed in Higo for six centuries before Sonkai's arrival, but their productions were limited to coarse household utensils. The principal of them was at a place called Tôda, near the flourishing seaport town of Yatsushiro. Opposite to the latter lies the large island of Amakusa, long renowned for the excellence of its potter's earth (*vidê Kame-yama-yaki*). Sonkai, or Kizo, settled at Toda, and using one of the clays of Amakusa, which gave a fine, iron-red *pâte*, produced a faience called at first *Tôda-yaki*, and subsequently *Yatsushiro-yaki*. It is one of the most delicate and æsthetic of all Japanese faiences. The *pâte*, as has been said, is of exceedingly fine texture, and its red colour, combining with the pear-grey of the diaphanous glaze—which in the older pieces is uniform, lustrous, and minutely crackled—produces a tint of great richness. The decoration generally consists of storks flying among clouds, or of simple combinations of lines and diapers. It is

peculiar in the fact that the designs are engraved in the *pâte*, and afterwards filled with white clay before glazing. It is, in short, a copy of the Korean pottery known in Japan as *Unkaku* (clouds and storks), to which, though slightly inferior in point of glaze, it is decidedly superior in beauty and delicacy of finish. But, on the other hand, neither the *Yatsushiro-yaki*, nor its Korean progenitor, can by any means bear comparison with the Chinese faience, which is the original of both. Another very favourite variety of this ware imitates the Korean *Hakime*, or "streaked" pottery, in which the white engraved design is intended to represent the marks (*me*) of a coarse brush (*haki*), the intention being to convey an idea of boldness and rapidity of finish. The potters of Yatsushiro confined themselves almost entirely to this inlaid decoration. They never used enamels or pigments of any sort. Their wares, therefore, require little description, the universal characteristics being a fine iron-red or dark-grey *pâte*, a tolerably lustrous glaze, varying from pearl-grey to dark brown, and white inlaid decoration, the clay of the latter showing crackle of greater or less fineness.

It is the Henri Deux ware of Japan, the modern ware is very pretty and interesting, but of course one prefers the old and original specimens, such as this old red koro.

Banko Ware (Faience).

At the village of Kuwana, in the province of Ise, between the years 1760 and 1795, there lived a rich merchant, by name Kuwanami Gozayemon, who, in the days of his prosperity, turned his thoughts to garden-making, that refined extravagance which has always been among the first fancies of a wealthy Japanese. Until that time Gozayemon had given himself little concern about the "Chajin" and their tenets, but his horticultural predilections necessarily drove him to seek the aid of those masters of æsthetics. To this end he visited Kyôtô, and there became the pupil of a renowned *virtuoso*, from whom he acquired, not the principles of garden-making alone, but also that taste for keramics which forms an integral part of the tea ceremonials. The memory of the great potter Kenzan was then fresh, and the Kiyomizu factories had attained the zenith of their excellence. The merchant of Kuwana, now an ardent disciple of the *Cha-no-you* ethics, never wearied of wandering from workshop to workshop and watching the clay assume, under the touch of skilled manipulators, shapes the beauties of which he had newly learned to appreciate. His interest gradually developed into a desire to imitate. The Kyôtô potters were easily persuaded to explain their processes, and whether their pupil possessed some innate ability, or whether, as a wealthy amateur, he was able to command the best materials and devote ample time to the manufacture of single pieces, it is certain that, by the circle of friends who were so fortunate as to receive the products of his kiln, he was pronounced one of the best artists of his day. Yet, like the majority of Japanese keramists, he was an imitator, not an originator. The thick, unadorned Raku ware, and the ill-favoured Korean faïences supplied models that seemed not less worthy of reproduction than the delicate conceptions of Ninsei, or the bold designs of Kenzan. In both directions, however, Gozayemon was eminently successful; so successful that his fame reached the court of Yedo, and a special order was sent to him from the Shogun Iyenari (1785). No doubt such a commission incited the amateur to more than common exertions, for the proficiency he displayed induced the Shogun to summon him to Yedo. He accordingly moved to Komme, in the north-east suburb of the Eastern Capital, where he already possessed a residence, and there pursued his keramic pastime, under the patronage of the court nobles, Iyenari himself sometimes condescending to visit Komme and watch the elaboration of results which he so much admired. The effect of all this upon Gozayemon's reputation can be easily conceived. His ware became the rage everywhere—not, perhaps, for the sake of its merits alone, but also because of the difficulty men experienced in procuring it: for fame had made the artist capricious, and, since he did not work for gain, none but the favoured few might obtain specimens of his handicraft. He now no longer restricted himself to imitations of the ancient models, but, giving the reins to his fancy, turned out pieces which combined the graces of the Japanese school with the brilliancy of the Chinese polychromatic porcelain. Just then, however, the factories of the Celestial Kingdom, under the munificent patronage of the Emperor Chien-lung, were producing wares not unworthy of their ancient fame; and, side by side with these, the inferiority of the Japanese keramist's enamels became easily apparent. The Shogun, therefore, commissioned the Governor of Nagasaki to procure from King-te-chang the recipes used at the Imperial factory, together with a supply of the best materials. One

is a little puzzled to conceive by what means these instructions were carried out, but the Governor seems to have experienced no difficulty, for within a year he forwarded to Yeddo all that was required. With this aid, Gozayemon's success was more marked than ever. The best connoisseurs could scarcely distinguish his pieces from the Chinese porcelain decorated with red and green enamels of the Wan-lieh period (1673-1720), though, indeed, it must be confessed that the models he copied do not exhibit any very remarkable degree of keramic skill. His imitations of the Delft faïence, too, were certainly quite as good as the very inferior specimens of that ware which found their way to Japan; but of his achievements in this line we need only say that they would not be admitted into any respectable European collection. He only became great when, departing from his models, he combined brilliantly glazed surfaces with chaste floral decoration in the pure Japanese style. He imitated everything, from the rude faïences of Korea, and the grand colours of Cochin-China, to the severest styles of Ninsei and Kenzan. He generally marked his pieces *Banko* (everlasting or enduring), sometimes, however, adding *Fuyeki* (changeless). His productions are now known as *Ko-Banko-yaki* (old *Banko* ware). He died about the year 1800, at Kuwana, whither he had been recalled by Matsu-daira, lord of Etchiu, one of the most celebrated of modern *virtuosi*. Whatever talent he possessed died with him, for, since he cultivated keramics entirely as a pastime, he neither took pupils nor imparted his art to his children. One of his relatives, by name Takekawa Chikusai, who resided at Izawa, in Ise, made some attempts to continue the manufacture, or, rather, sought to obtain a market for his own wares under the ægis of the *Banko* stamp. But his productions were only tolerable so long as the materials left by Gozayemon remained unexhausted.

Like all noted amateurs, Gozayemon would probably have found imitators in later times. Yet, had it not been for an accident, his name would certainly be little remembered outside the circle of connoisseurs, of whose somewhat archaic creed he was so obedient a disciple, and in whose hands his comparatively scanty productions remained. That accident was the discovery—about the year 1830—of a recipe which he had employed in the manufacture of his enamels. The document containing the precious formula had found its way into the possession of a dealer in *bric-a-brac*, who lived at Kuwana, and whose son, Mori Yusetsu, had already gained some distinction as an imitator of *Raku* faïence. Fully appreciating the value of the knowledge thus strangely acquired, Yusetsu immediately set himself to profit by it; and, in order to give his counterfeit ware a greater semblance of authenticity, he persuaded Gozayemon's grandson to sell him the *Banko* stamp. Thus the works of the Ise amateur were again brought into public notice, and that rather by a freak of fortune than by any public knowledge of their merits. Yusetsu, however, was saved from performing the ignoble *rôle* of a mere imitator by his quickness of observation, for, detecting that the Chinese artists—whose works, like Gozayemon, he took as his models—used moulds applied internally for their more elaborate pieces, he immediately adopted that method in his own workshop, and so caused the name of *Banko*—for he still continued to employ Gozayemon's stamp—to be associated with the introduction of a valuable novelty in Japanese keramics. It has already been noticed that the Kyôtô artist, Mokubei, was the first to follow the Chinese example in the matter of moulds; but, whereas he fashioned his clay *in* the mould, Yusetsu reversed the process by putting the mould inside the vase, and pressing the clay with the hand into the matrix. The consequence is that his pieces carry their designs on the inner as well as the outer surface, and are, moreover, thumb-marked. Of course a mould thus employed was necessarily constructed on principles different from those which governed the Kyôtô process. Accordingly, we find that the mould of Yusetsu, instead of being simply divided into two parts, was built up of six, or eight, or sometimes twelve, longitudinal sections, which were withdrawn one by one after they had accomplished their end. The results displayed such clever modelling that they subsequently came to be regarded representative pieces of *Banko-yaki*. In fact, it is through the works of Yusetsu, or, rather, through the methods he devised, that the Ise ware has attained the wide-spread popularity it now enjoys; nor that undeservedly either, for some of the designs of his school exhibit a remarkable combination of artistic and technical excellence. Particularly worthy of mention are pieces ornamented with storks, dragons, and so forth, in relief, and others with clever arabesques in coloured slips on a green or rich

brown ground. All the *Yusetsu Banko* ware is faience, and the specimens are sometimes stamped "*Yusetsu*." Among his productions, a variety which often passes, or is made to pass, for "*Ko-Banko*," is a finely crackled faïence of a dark cream tint, decorated with blue under the glaze, and above it with a preponderance of red diapers, among which are reserved medallions containing landscapes or mythical subjects. Pieces in this style bear a considerable resemblance to the modern *Akahada-yaki*, but even in the absence of marks, the two may be readily distinguished, not only by the omission of the blue in the latter, but also by its denser *pâte* and the yellowish tinge of the body-glaze. The collector will generally be safe in attributing specimens of this nature to Yusetsu. Yuyeki, originally called Yohei, a younger brother of Yusetsu, was also an able artist—better, indeed, than Yusetsu himself, according to some authorities—and Mori-Yogozayemon, the present representative of the family, still carries on the manufacture. The reader will perceive, however, that in the hands of Yusetsu and his successors the *Banko* ware underwent a complete change of character. Of the finest old *Banko* enamelled ware I know no grander specimen than this magnificent plate. It followed me from Japan, for I could not acquire any really great example while I was there, and left a commission with Mr. Wakai, which he acquitted with his customary fidelity and good taste.

Sanda Ware (Celadon)—(Stoneware).

The province of Setsu lies at the head of the Izuminadi, which may be called the northern entrance to the Inland Sea. It contains the flourishing city of Osaka, and the foreign settlement of Kôbe. For many years Osaka has occupied the first place among the keramic marts of Japan, and, to this day, its *bric-a-brac* shops have no equals elsewhere in the empire. Yet the province possesses few keramic factories worthy of note. The principal is that of *Sanda*, established about the year 1690, by order of Kuki, lord of the district. The early *Sanda-yaki* was a pottery, closely resembling that of Tamba (*vide Tamba-yaki*); but, towards the end of the 18th century, two workmen, Uchigami and Ippei, succeeded in making themselves acquainted with the porcelain methods of Arita. Their ambition, apparently, was to copy Chinese celadon; but it was not till they obtained from Kyôtô the assistance of Shûhei, Kumachichi, and Kamesuke, pupils of the celebrated Rokubei, that they accomplished anything worthy of note. Then, indeed, their imitations of the much-esteemed "sea-green" became so excellent, that the achievements of all other artists in this regard were forgotten, and the term *Sanda-seiji* gradually passed into a synonym for Japanese celadon. It may be well, however, to remind the reader that more than a century before the appearance of the *Sanda-seiji* a celadon of much better quality had been produced at the Hizen factories, under the special patronage of Nabeshima, lord of the province. It would, therefore, appear that the celebrity enjoyed by the celadon of Setsu was in some degree a question of quantity, for while the outcome of the Hizen workshops in this particular variety was very small, being, in fact, confined to pieces for special use or presentation purposes, that of Sanda was abundant. In colour, the *Sanda-seiji* is a bright green, lacking the warmth of the Chinese *Schichi-kan-seiji* and the delicacy of the Nabeshima ware.

These Sanda cocks, this seated figure, and the water-jug, are characteristic examples, which you will judge for yourselves.

Miscellaneous.

Another great name among the Kyôtô keramists is that of Dohachi Takahashi, a contemporary of Zengoro Hozen. He commenced his career at a workshop in Gojo-zaka (Kyôtô) about the year 1825. He was a potter of considerable technical skill in the manufacture of his glazes, one of which, a peculiar dull white with a tinge of pink, is almost equal to Ninsei's work from which it was copied. The designs on his faïence also exhibit some of the most graceful conceptions of the truly Japanese school. In the year 1830, his reputation had become so well established that we find him employed as an instructor by the potters of Takamatsu, in Sanshu, and Himeji, in Banshu. It is curious, however, to observe that even at this late period of the art's history, alien influences are still perceptible. Prior to the enforced immigration of Korean workmen, the Taiko had attempted to achieve a mutual engrafting of the two countries' styles by importing, as models for the keramists of Japan, a quantity of Korean faïence. The chief characteristic, and, indeed, the only redeeming feature of the latter, which was called *Gohon*, or "Pattern-ware," consisted in light pink tints or flecks in the glaze, and these we often find exactly reproduced in Dohachi's best pieces;

side by side with designs not unworthy of Tanyu's brush. Strange that, after the lapse of two cycles and a half, the "plebeian prince's" conception should have been so perfectly realised by one of his country's most æsthetic artisans! In his old age Dohachi took the name of Ninami, with which also he marked some of his pieces. In general, however, he used the ideographs Do-hachi for this purpose.

Some Modern Potters.

I have left myself little time or space for speaking of some of the modern potters. Their work is exemplified on a table before you. I regret that I have not room in my collection —for room is our great difficulty in London— for larger specimens of their very fine work. The work of Rokubei of Seyfou, of Taizan and Tanzan at Kyôtô; of Inouyé of Tokio, of Maizan at Osaka, of Makuzu at Yokohama, is of the highest artistic merit. Rokubei is faithful to the traditions of the old Japanese school. His landscapes are still reminiscences of Tanyû, who painted on his ancestor's wares; and they take us back to the feudal traditions and the day of the tea ceremonies of Hideyoshi. I vainly tried to induce him to part with his ancestral series of specimens, but he is going to reproduce them for me (duly marked as copies). Seyfou is a genius, for whom the rarest glazes present no difficulties which he cannot overcome. His violets, aubergines, corals, and cobalt blues are extraordinarily brilliant and pure; and Makuzu, now that he has left off inundating us with sham Satsuma of gorgeous colouring and over-grown pretentiousness—of which I have also seen specimens enthroned in state in collections all over the world—is showing himself in his true light as a potter capable of rivalling the Chinese ancients in their most secret arts. Unhappily, his pieces are now being bought in China, and we may expect to see his extraordinary skill in glazes once more put to unfortunate uses. Maizan's decoration of Satsuma is illustrated in his larger style into groups before you. His exquisite miniature painting of chrysanthemums and butterflies, his missal-like figure-pieces, having the delicate character of old illuminations of mediæval MSS., are world-famous. He is, besides, one of the most modest, accomplished, and trustworthy of connoisseurs. His work is all signed, and will constitute one of the most interesting features of the exhibition of artistic pottery at Chicago, which will, I anticipate, be very fine.

DISCUSSION.

The Chairman said Mr. Hart had told them so much, that it would be difficult to select any points towards which discussion could specially be directed; but, in one or two directions, he thought Mr. Hart had opened up an important field of consideration: these were the relations of Japan to China in the keramic art, and the relations of Japan to Europe. In the relations of Japan to China, we had seen that the first decorative porcelain which the Japanese had produced was produced after a visit to China. At first this was blue under the glaze. At a later period, the enamels laid on over the glaze were apparently derived from personal instruction from a Japanese potter. Still later, special glazing had been introduced by Koreans and Chinese. The Japanese were largely indebted to China. In the relation of modern China, any one who knew the work the Chinese were producing, would see how far the pupils left behind their early teachers. There was nothing in modern China which would compare with the work produced from scores of kilns in Japan. In connection with the relation of Japan to Europe, it was only necessary to point out that all our fabriques in Europe were stimulated by the introduction of works which the Japanese did not think good enough to keep for themselves, work which they produced to give to us; and, even now, he was afraid the relations between Europe and Japan were by no means of the most flattering kind, as the Japanese sent to Europe work which none of them would possess.

Mr. Sleaden remarked that while the best examples of Japanese ware went to America, so also did the very worst; so that, while we could not compliment ourselves on our taste, as compared with the Japanese, we were not so bad as the Americans, and if we did not buy the best pieces, it was because our wealth was not so great. It was the very rich men in America who were able to buy those costly pieces.

Mr. Diosy said even the very worst forms of keramic ware, which the Japanese shot on to the rubbish heap of the commercial market in this country, served a purpose. Even the very commonest Japanese ware made for export had, in many cases, a certain charm about it, and very often qualities which were not to be found in goods of the same description and value made here. For instance, in a small tradesman's household, or on a cottager's mantelpiece, you might see a pilgrim bottle at 8¾d. Of course, it was not a very fine piece, and would probably be of a violent colour, which would horrify Mr. Hart; but it displaced a little white shepherdess, with gilt eyes and gilt lips, and a little gilt lamb by her side, which was a much greater crime against all good taste than even a slightly misshapen pilgrim bottle. Even a little imitation of Banko ware, given away with a 2 lb. packet of tea, was a better

education to the eye of a cottager than a Venus in Parian, who had become web-fingered through the exigencies of cheap casting. Therefore, though he hoped that Japan would, in time, send us only its good wares which did honour to its excellence, still a good deal of what was classed as rubbish was an advantage, inasmuch as it replaced much worse articles.

Mr. HUGH STANNUS said he for one was grateful for the clear light which Mr. Hart had cast on the past by his lucid explanation, and by the valuable specimens he had exhibited. He (Mr. Stannus) hoped that Mr. Hart would consider the possibity of a systematic nomenclature for these ornamental vases. People talked about gourd-shaped bottles, and so on, but there was no definite set of names such as were applied to Greek vases, and were well known to all. It would help the study of Japanese work, which he felt sure would receive a fresh development from this admirable paper, if some definite names were agreed on.

Mr. ERNEST HART, in reply, said a system of nomenclature did exist in fact, but Japanese was so much less familiar than Greek to most people, that he feared the terms were not generally recognised. If anything, there was an excessively minute nomenclature current in Japan, and some of the native connoisseurs had been rather grateful to Englishmen for substituting a more scientific and artistic system of criticism for their own, which consisted mainly of a system of shapes and uses. Any suggestion coming from such an excellent authority, and in itself so reasonable, would be well worth consideration, and no doubt the Chairman and other members of the Council of the Japan Society would take an opportunity of having it discussed.

The CHAIRMAN then proposed a hearty vote of thanks to Mr. Hart, which was carried unanimously, and the meeting adjourned.

Correspondence.

SIAM.

Are not the Panthays of Lord Lamington's valuable paper (p. 282) the Mussulmans who were expelled or fled from Yunnan after the defeat of Yakoob Beg?

HYDE CLARKE.

BURNING OILS FOR LIGHTHOUSES AND LIGHTSHIPS.

Your correspondent, Mr. William Love, as the representative in London of the Broxburn Oil Company, is entitled to be heard on behalf of the Scottish mineral oil industry, but, in the letter published in your last issue, he has certainly not exhibited that knowledge of the subject which he might fairly have been assumed to possess.

In the first place he takes exception to my statement that the definition of "inflammable liquid," in relation to lighthouse oil in the Inflammable Liquids Bill, was not objected to by the delegates of the Scotch oil companies, as likely to create a misapprehension, and as being somewhat misleading. He adds that "in the trade conference of 1891 the question of the standard of safety was purposely never under discussion, as the general provisions of the Draft Bill submitted for their consideration were felt to be so onerous that united trade action had become a necessity." Let us see what the circumstances of the case are. In 1891 there was a Bill, not a "Draft Bill," and the use of the latter term points to the conclusion that Mr. Love is referring to the trade conferences with Colonel Majendie in 1888, when the heads of the proposed Bill (substantially the Draft Bill) were under discussion. But whether he is or not, the fact remains that the definition of inflammable liquid was discussed, was actually modified at the request of the representatives of the Scotch oil companies, and appeared in the Inflammable Liquids Bill in the form in which it had been accepted by those representatives. I find that there were four delegates of the Scotch oil companies present when Mr. Mann, of Young's Paraffin Light and Mineral Oil Company, made the following remarks (I quote from the verbatim shorthand report, reprinted for circulation last year by the Petroleum Defence Committee:—"I beg to submit a suggestion that at p. 3, cl. 2, the specific gravity of ·865 be reduced to ·840, and the flashing-point of 200° to 150°. . . . . It would be a special relief to the Scotch trade, which has suffered for some time back, and has been almost annihilated, from low prices, if this specific gravity test were reduced to ·840. If the Government has fixed the point of safety for a flashing-point of other oil, and no doubt wisely fixed it, at 73°, I submit that a flashing-point of 150° for this oil may safely be adopted."

These remarks had special reference to intermediate oil, but they indicate very clearly that, as I stated at the meeting, the Scotch oil representatives did not take exception to the definition in relation to lighthouse oil at the time, when it is reasonable to suppose they would have done so if they had objected to it. They further show that Mr. Mann, the spokesman of the Scotch oil representatives, considered that the standard had been "wisely fixed" at 73°. So much for definition.

In the next place, Mr. Love, addressing himself to

the general question of the test standard in relation to accidents with lamps, seeks to prove that the standard of 73° F. is too low, and that if it were raised to 100° F., mineral oil complying with that test might be used without liability to accidents. To the experiments quoted by Mr. Love as having been made by Dr. Thörner, or rather to the deductions drawn from the results of them, I make the same objection that I did in the case of Mr. Price Edwards' experiments, and I must confess to some surprise that Mr. Love should have committed himself to the statement that "high-test oils, therefore, which give off no vapour under 100° F. never reach the point in ordinary domestic lamps at which vapour can be produced, and, consequently, safety in their use is insured." That very considerable heating of the lamp may take place in burning some descriptions of oil of high flashing point has been demonstrated. Thus the destruction by fire of the training-ship *Goliath* off Grays, in 1875, was due to the dropping of a mineral oil lamp which had become so hot that the boy who was instructed to remove it could not hold it, and it was proved at the inquest that the oil in use had been specially selected on account of its exceptionally high flashing point. The recent fatal accident to a well-known nobleman also affords indisputable evidence of the risk that may attend the use of high-test oil in lamps of imperfect construction, for in this instance the oil had a flashing point of 110° F. (Abel test), and it is worthy of note that, in a previous similar accident to the same nobleman, resulting in personal injuries, oil of the same high flashing point was implicated.

In the remarks which I made at the meeting, I desired to counteract the impression likely to be conveyed by the statements of Mr. Price Edwards, that an oil of high flashing point was necessarily one which could be used with safety, for as Sir Frederick Abel very clearly demonstrated in a lecture delivered at the Royal Institution, in 1885, safety in the use of mineral oil lamps is not to be secured by the employment of oils of very high flashing-point. I maintain that the exisiting standard of test has not been shown to be too low; and I may remark, in conclusion, that this attitude is not inconsistent with the advocacy of the use, under certain circumstances, of oils of higher flashing-point, apart from the fact that such oils may be selected on the ground of other qualities which they also possess.

Mr. Love is unfortunate in citing the late Mr. Charles Marvin in support of his views; for I am reminded that, in a letter, published in the *Globe* in 1888 (July 3rd), Mr. Marvin used these words:—"The allegation of a Midland firm of lamp makers, that most of the accidents are caused by under-standard petroleum, is about as satisfactory as the allegation of the Secretary of the Scottish Mineral Oil Association, in 1886, that no accidents had occured with Scotch paraffin for 37 years."

BOVERTON REDWOOD.

February 24th.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock:—

MARCH 2.—Prof. VIVIAN B. LEWES, "Spontaneous Ignition of Coal, and its Prevention." Sir FREDERICK BRAMWELL, Bart., D.C.L., F.R.S., will preside.

MARCH 9.—A. P. LAURIE, M.A., "Experiments on the Durability of Modern Pigments."

MARCH 16.—TEMPEST ANDERSON, M.D., "Iceland."

MARCH 23.—GILBERT R. REDGRAVE, "Manufacture and Industrial Application of Flexible Tubing."

MARCH 30.—EWING MATHESON, "Foreign Exchange."

Papers, the dates of reading of which are not yet fixed:—

"The Fisheries Department: its Position and Prospects." By J. W. WILLIS BUND.

"The Congo State." By Captain V. LOVETT CAMERON, R.N., C.B.

"Colour Blindness." By Captain W. de W. ABNEY, C.B., F.R.S.

"Uses and Applications of Aluminium." By G. L. ADDENBROOKE.

FOREIGN AND COLONIAL SECTION.

Tuesdays, at Half-past Four or Eight o'clock; due notice of the hour will be given:—

MARCH 15.—F. A. PEZET (Peruvian Consul General), "Peru: its Commerce and Resources." CLEMENTS R. MARKHAM, C.B., F.R.S., will preside. 8 p.m.

APRIL 5.—The Rev. JOHN MCLEAN, D.D. "Manitoba and the North-West Provinces of the Dominion."

APRIL 26.—Sir EDWARD BRADDON, K.C.M.G., "The Progress of Australasia."

MAY 24.—Colonel HOWARD VINCENT, C.B., M.P., "The Extension of Colonial Trade."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

MARCH 3.—Surgeon-General Sir WILLIAM JAMES MOORE, K.C.I.E., "Indian Sanitation and the International Congress of Hygiene." Major-Gen. Sir OWEN TUDOR BURNE, K.C.S.I., C.I.E., will preside.

MARCH 24.—G. H. M. BATTEN, formerly of the Bengal Civil Service, "The Opium Question." Sir JOHN STRACHEY, G.C.S.I., C.I.E., will preside.

APRIL 7.—Dr. J. AUGUSTUS VOELCKER, "The Agricultural Needs of India."

APRIL 28.—Sir WILLIAM WEDDERBURN, Bart., "Reorganisation of Agricultural Credit in India."

MAY 19.—JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock:—

MARCH 29.—E. ROSCOE MULLINS, "The Decorative Uses of Sculpture." ALFRED GILBERT, A.R.A., will preside.

APRIL 12. — C. PURDON CLARKE, C.I.E., "English Brocades and Figured Silks." The LORD MASHAM will preside.

MAY 17.—GEORGE J. ROBINSON, "Decorative Plaster Work" (II.). J. HUNGERFORD POLLEN will preside.

MAY 31.—WILLIAM DE MORGAN, "Lustre Ware."

There will be no meeting on March 8, as previously announced. This will be replaced by a meeting on May 31.

CANTOR LECTURES.

Monday evenings, at Eight o'clock:—

PROF. WILLIAM ROBINSON, M.E., Assoc-M.Inst.C.E., "The Uses of Petroleum in Prime Movers." Four Lectures.

LECTURE I.—FEBRUARY 29.—*Properties and Uses of Petroleum in Prime Movers.*—Oil testing—Specific gravity, flashing point, composition—Expansion—Distillation—Vaporisation of oils—Spray-making and carburetting devices in modern oil-engines—Pressure of petroleum vapours at different temperatures—Behaviour of different kinds of oil in engine cylinder—Other properties of petroleum as heating and working agent.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 29...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Prof. William Robinson, "The Uses of Petroleum in Prime Movers." (Lecture I.)

Farmer's Club, Salisbury-square Hotel, Fleet-street, E.C., 4 p.m. Prof. Axe, "Abortion in the Live Stock of the Farm."

Surveyors, 12, Great George-street, S.W., 8 p.m. Discussion on Mr. J. W. Grover's paper, "An Explanation of the London Water Question."

Royal Scottish Society of Arts, George-street, Edinburgh, 8 p.m. 1. Mr. John Foggie, "The Analytical Aspect of Ventilation by the Propulsion and Extraction Systems, in relation to Organic Matter and Micro-Organisms in the Air." 2. Mr. William Key, "The Ventilation of Buildings mechanically by Propulsion, with Screened, Washed, and Warmed Air, without Draughts."

Actuaries, Staple-inn-hall, Holborn, 7 p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Israel Gollancz, "The Saga of Hamlet."

TUESDAY, MARCH 1...Royal Institution, Albemarle-street, 3 p.m. W., Prof. Victor Horsley, "The Brain." (Lecture VII.)

Central Chamber of Agriculture (at the HOUSE OF THE SOCIETY OF ARTS), 11 a.m.

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m. Annual Meeting.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on papers by (1) Mr. W. T. Douglass, "The Bishop Rock Lighthouses;" (2) Mr. David C. Salmond, "The Illumination by Gas of Tory Island Lighthouse, Co. Donegal."

Pathological, 20, Hanover-square, W., 8½ p.m.

Biblical Archæology, 9, Conduit-street, W., 8 p.m.

Zoological, 3, Hanover-square, W, 8½ p.m.

WEDNESDAY, MARCH 2...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Prof. Vivian B. Lewes, "Spontaneous Ignition of Coal, and its Prevention."

Entomological, 11, Chandos-street, W., 7 p.m.

Archælogical Association, 32, Sackville-street, W., 8 p.m.

Obstetrical, 20, Hanover-square, W. 8 p.m.

Civil and Mechanical Engineers, 7, Westminster-chambers, S.W., 7 p.m. Mr. R. J. Friswell, "Some Practical Notes on the Water Supply of Boilers."

THURSDAY, MARCH 3... SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Surgeon-General Sir William James Moore, K.C.I.E., "Indian Sanitation and the International Congress of Hygiene."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. A. D. Michael, "Variations in the Internal Anatomy of the *Gamasina*." 2. Mr. Allan Swan, "Vitality of Spores of Bacillus."

Chemical, Burlington-house, W., 8 p.m.

London Institution, Finsbury-circus, E.C., 7 p.m. Dr. A. C. Mackenzie, "Orchestral Music in the 16th Century.

Royal Institution, Albemarle-street, W., 3 p.m. Prof. W. P. Ker, "The Progress of Romance in Middle Ages. (Lecture I.)

Archæological Institution, Oxford-mansion, Oxford-street, W., 4 p.m.

FRIDAY, MARCH 4... United Service Inst., Whitehall-yard, 3 p.m. Lieut. F. J. Davis, "The Employment of Photography in Reconnaisance."

Royal Institution, Albemarle-street, W., 8 p.m. (Weekly Meeting, 9 p.m.) Prof. L. C. Miall, "The Suface Film of Water, and its Relation to the Life of Plants and Animals."

Geologists' Association, University College, W.C., 8 p.m.

Philological, University College, W.C., 8 p.m.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Physical, Science Schools, South Kensington, S.W., 5 p.m. 1. Prof. S. P. Thompson, "Modes of Representing Electromotive Forces and Currents." 2. Prof. Maurice Fitzgerald, "The Flexure of Long Pillars under their own Weight." 3. Prof. J. Perry, "Choking Coils."

SATURDAY, MARCH 5...Saturday Lecture Society, Lecture Theatre, South Kensington Museum, S.W., 3 p.m. Prof. W. C. Roberts-Austen, "Art Metal-work."

Royal Institution, Albemarle-street, W., 3 p.m. Lord Rayleigh, "Matter: at Rest and in Motion." (Lecture IV.)

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

Journal of the Society of Arts.

No. 2,050. Vol. XL.

FRIDAY, MARCH 4, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CANTOR LECTURES.

The first lecture of the course, on "The Uses of Petroleum in Prime Movers," was delivered on Monday evening, 29th ult., by Prof. WILLIAM ROBINSON. The lectures will be printed in the *Journal* during the summer recess.

Chicago Exhibition, 1893.

MEETING OF THE ROYAL COMMISSION.

A meeting of the Royal Commission was held on Wednesday, 2nd inst. Present: The Attorney-General, M.P., Chairman of the Commission, in the chair; Sir Frederick Abel, K.C.B., D.C.L., F.R.S., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Sir Frederick Bramwell, Bart., D.C.L., F.R.S., Major-Gen. Sir Owen Tudor Burne, K.C.S.I., C.I.E., B. Francis Cobb, Prof. James Dewar, M.A., F.R.S., Sir James N. Douglass, F.R.S., James Dredge, Sir Douglas Galton, K.C.B., D.C.L., F.R.S., C. Malcolm Kennedy, C.B., Professor W. C. Roberts-Austen, C.B., F.R.S., with Sir Henry Trueman Wood, Secretary of the Commission.

COMMITTEE ON AGRICULTURE.

A meeting of the Agriculture and Food Products Committee of the Royal Commission for the Chicago Exhibition of 1893 was held on Monday, 29th ult., at 12, Hanover-square. Present:—Earl of Feversham, President of the Royal Agricultural Society, in the chair; R. Bannister, James Bell, D.Sc., C.B., F.R.S., J. Bowen-Jones, W. Burdett Coutts, M.P., Earl Cathcart, Earl of Coventry, Alfred Darby, Walter Gilbey, John Gilmour, Captain Heaton, Lieut.-General Michael, C.S.I., Ralph Palmer, Albert Pell, G. H. Sanday, John Thornton, Dr. J. Augustus Voelcker, and Ernest Clarke, Honorary Secretary of the Committee.

LADIES' COMMITTEE.

A meeting of the Committee of Ladies for the Women's Work Section of the Chicago Exhibition was held on Wednesday afternoon, 2nd inst. Present:—H.R.H. Princess Christian, President of the Committee; the Marchioness of Salisbury, the Countess of Aberdeen, Lady Agnes Burne, Lady Egerton of Tatton, Lady Knutsford, Lady Galton, Lady Jeune, Lady Roberts, Mrs. Tyssen Amherst, Mrs. Bedford Fenwick, Mrs. David Carmichael, Mrs. Priestley, Mrs. Roberts-Austen, Miss Forsyth, Miss Emily Shaw-Lefevre, Miss Webster, and Miss Fay Lankester, Secretary of the Committee. The following members of the Royal Commission also attended:—The Attorney-General, M.P. (Chairman of the Commission), Sir Frederick Abel, K.C.B., Sir George Birdwood, K.C.I.E., Major-General Sir Owen Tudor Burne, K.C.S.I., and Sir Douglas Galton, K.C.B., with Sir Henry Trueman Wood, Secretary of the Commission.

COMMISSION FOR BERMUDA.

The Governor of Bermuda has informed the Secretary of the Royal Commission that the Colonial Legislature have made a grant to provide for the representation of the Colony at the Exhibition, and that a Commission has been appointed for the purpose of making the preliminary arrangements.

APPLICATIONS FOR SPACE IN THE BRITISH SECTION.

Applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, and addressed to the Secretary, as above. Applications can now only be received subject to space being available.

Proceedings of the Society.

APPLIED ART SECTION.

Tuesday, February 23rd, 1892; Sir PHILIP CUNLIFFE-OWEN, K.C.B., K.C.M.G., C.I.E., in the chair.

The paper read was—

ARTISTIC TREATMENT OF JEWEL AND ADDRESS CASKETS.

By J. William Tonks.

The subject I have chosen for this evening has been invested from the earliest times with an atmosphere of poetry and romance. It is a central element of one of the most interesting Greek myths; it furnishes a principal scene in one of Shakespeare's finest dramas, and it has in all ages been adopted as an apt and suggestive symbol. Thus an old poet exclaims:—

> "O ignorant poor man! What dost thou bear
> Locked up within the casket of thy breast?
> What jewels and what riches hast thou there
> What heavenly treasure in so weak a chest?"

It is more significant that in the most ancient literature to which we have access, a casket, a box, an ark, contained the most sacred religious symbols, while its golden summit reflected the messages of mercy from the Most High. We are told that Bezaleel (Exodus xxxvii. i. 9., revised version), the earliest goldsmith whose name has come down to us on the tide of history, made an oblong box, whose proportions were strikingly similar to those adopted for caskets in the best periods (2½ by 1½ by 1½), for the purpose of containing sacred symbols. The box itself was of acacia wood, this material being of an enduring character; and this body was lined and covered with gold. A crown, or raised moulding of gold, was placed along the upper edge. Then four rings of gold were fixed on the lower sides or literally "ribs" of it, through which were placed two thin poles or staves, also covered with gold, and by means of which it was carried about after the manner of a palanquin. The box was covered with a dome or "mercy-seat" of gold, so made that it could attract light and focus its effulgence to the spectator. At each side were mystic, winged figures of cherubim, of beaten work in gold, facing each other, and with wings stretched on high towards each other, in striking resemblance to the style adopted in portraying winged figures in the most ancient Egyptian hieroglyphs.

This description is of importance, not only as marking a high degree of artistic achievement, but as also affording a kind of model upon which works of this kind in various countries have afterwards been constructed. It derives additional interest from its close relation to early Egyptian forms, and which to some extent it aids in explaining. In the magnificent series of illustrations prepared under the direction of Champollion le jeune, during the invasion of Egypt by Napoleon I., there is a remarkable drawing which I have roughly figured. It represents a box of ancient character, having a rim or moulding, the form observing the proportion of 2½ by 1½, and having in centre of body two open eyes, probably representing the unsleeping watchfulness of the Almighty. This box, curiously enough, has two poles or staves, and these proceed from the ribs, in fact they partly complete the form of a highly conventional lion. The lion, as suggestive of power, is evidently symbolic. Another singular figure, also from Champollion, is an ensign, apparently formed of a sloping side box, with an animal, perhaps a fox, seated on top. I fear this is attributable to a much later period, as there is in the South Kensington Museum a wooden box very similar in shape, but without any figure surmounting it, and which may be either a casket, or a *chasse*—a depository of the relics or ashes of the dead.

Coming from Egypt to Greece, a true historic transition, we first begin to find the jewel casket. This was called by the Greeks and Latins "pyxis," probably because originally made of box-wood, and in it they placed and kept for safety their parures or jewels. The simple box-wood caskets, quite adequate in those early days, are often figured upon the exquisite vases that have come down to us. I have here enlarged two specimens from vases in the famous Englefield collection. They are oblong, simple in form, consistent with their use, and with the purpose they were designed to serve, the decoration being always in conventional and geometric bands. The proportion usually adopted is still that of the sacred box or ark of the Israelities, 2½ by 1½ by 1½. I know but of one example in the cubic form, but that again illustrates the principle. It is that of the statue of Venus rising from the sea, in the Chigi palace. The goddess has one of these oblong caskets at her feet, thus sufficiently indicating their use and the devotion of their contents to the adornment and service of beauty.

It is a singular and suggestive fact that in the Greek mythology, a box or casket is intimately related to the first mortal woman who was created. Prometheus, one of the earliest mortals, whose name has ever since been held as the synonym of Genius, exceeded all others, we are told, in ability and artifice, so much so that he was able, at a famous sacrifice, to deceive even Jupiter, the chief of the immortal gods. To punish him and his

fellows, Jove is said to have taken fire away from the earth. But, assisted by Minerva, the goddess of Wisdom, the undaunted Prometheus climbed the heavens, and stealing fire from the chariot of the Sun, brought it down with him to the earth. The father of gods and men, enraged at such audacity, ordered Vulcan to make a woman of clay, and, after giving her life, to send her to Prometheus, with a casket of costly presents from the gods. As soon as she was endowed with life, all the gods and goddesses of Olympus vied with each other in presenting her with gifts. Beauty and the art of enrapturing the children of men she received from Venus, and from the Graces all their captivating charms. Apollo taught her to sing divinely, Mercury gave to her the most persuasive eloquence of a woman's tongue, and Minerva blest her with a wise discretion. Hence she was called Pandora, from Greek words signifying "all-gifted." But Jupiter himself presented her with a last and fatal gift. It was a casket filled with innumerable ills, which she was desired to offer to the mortal who espoused her. Mercury himself conducted this lovely creation to Prometheus, clad in all her charms. The wary and sagacious mortal, whether from the lofty disdain born at times of highest genius, or from a cool judgment which led him to suspect that there was danger in the all too glorious vision, to the surprise and anger of the immortals, declined the proffered bliss. Unfortunately for poor humanity, Prometheus had a brother, Epimetheus, less wary, or more sensible to female charms, who was entranced by the beauty of the heaven-descended maiden, and immediately rushed into her arms. He married her, received the box, opened it in haste, when there issued from it a multitude of evils and distempers, which speedily dispersed themselves over all the earth, and which have not since ceased to afflict mankind. He shut the casket again in haste; but nearly all were gone. Hope alone, which Jove had compassionately enclosed in this unhappy gift, had not time to escape from the box. Hope, therefore, remains as the only consolation left to unhappy mortals amid all the ills that flesh is heir to.

This beautiful myth is so closely related to my subject, that I could not forbear recounting it. The curious may find in it a singular analogy, with the symbolic allegory of the origin of evil, given in the most ancient portion of the Hebrew Scriptures. The Greek form is much later, is less direct, and more poetic in treatment; but the fact that, in Greek myth, Deucalion, the grandson of Pandora, is the Noah of the Grecian Flood, seems to emphasize the conclusion. It might almost have been thought, that as a casket, the dower of a woman, was the source of such mischief, it would have been a discarded object. But this was not so. The joy-loving Greek might laugh at the early perils of the jewel-box, the witty poet might fable in veiled satire the dangers of the female love of ornament, but the casket, nevertheless, grew richer and more decorative age by age. The wooden box was overlaid with ivory, silver, and, at last, gold, with gems and other costly materials, treated generally with panels, and in conventional style, as seen on the later Greek vases. During the Roman period, as riches and luxury increased, these naturally became more elaborate. Dress and ornaments with many became the chief object of attention, until a lady's toilet and ornaments became known as *mundus muliebris*, her world.* There came into use a special case, formed of some rich material, called *Dactylotheca*, wherein a large array of rings were kept.†

It is a matter of interest that one of the first gold caskets of which we have a record has relation to a remarkable Roman custom, in which—contrary to the Greek legends—the sterner sex were concerned. It was a habit to allow the beard to grow until about the age of 21; the young man then began to shave, and the first crop of beard was consecrated to some god; the day was held as a festival, and presents were sent to the young shaver by his friends.‡ Thus, the young Nero, whose early reign was as promising as its end was infamous, consecrated his beard to Jupiter Capitolinus, enclosing it in a veritable golden casket (*pyxide aurea*), the borders being set with pearls.‖ The melancholy fact is, in regard to all these examples, doubtless exhibiting, in a high degree, the art, as well as the luxury, of each successive period, that nothing now remains to us but an accidental record. This was, indeed, hardly to be expected in regard to the Roman world. As Byron powerfully expresses it:—

> "The Goth, the Christian, time, war, flood, and fire
> Have dealt upon the seven-hilled city's pride;
> She saw her glories, star by star, expire,
> And up the steep barbarian monarchs ride,
> Where the car climbed the capitol."§

* Liv. xxxiv., 7. † Martial xi., 60. ‡ Juvenal, iii. 187; Petron. 29. ‖ Suet. Ner. 12. § "Childe Harold," c. lxxx. 4.

By the burning of the Alexandrian Library, even the record of these pieces is mainly lost. There were, indeed, general causes, which have operated through long ages, and have prevented our being able to refer to examples of these far-off times. The very richness of the material has occasioned the loss of many artistic treasures; the cupidity, the necessity, the repeated disorders of so long a course of canturies have ensured their destruction; while fashion, that goddess of change, whose destructive worship belongs to every age, as M. Labarte remarks,* has contributed even more than these combined causes to the breaking up of the finest specimens of the goldsmiths' art. It is only, therefore, by the examples left us, in materials which it would hardly pay to disfigure or destroy, that we can pursue the historical aspect of our subject.

It seems a far cry from the gold casket containing the beard of Nero, to those enclosing mementos of martyrs of the Christian Church, but such is the irony of historic fate. The custom arose, even in the early times of Christianity, to take out of the catacombs memorials and even portions of the remains of martyrs and other saints, to enclose them in boxes or other ornaments, and to wear them as amulets. Such small holders were generally worn on the breast, from which they receive their name "encolpia." They were mostly small rectangular caskets of precious metals or of common materials, ornamented with the emblems of the Saviour or with Biblical illustrations. Two golden encolpia of this kind were found, in the 16th century, in the grottos of the Vatican. The simplest holders of such relics are the numerously-occurring caskets and round boxes of ivory, adorned with ornaments or with reliefs, also caskets of fine kinds of wood, or such as are covered with embroidery and enamels. Perhaps the most valuable—at any rate, the most significantly artistic work of this kind—is an antique onyx vessel, with a relief picture in the style of Greek art, in the treasury of the Abbey Church of St. Maurice in Wallis, and which, according to tradition, was a present of Charlemagne.

Here let me say a word in reference to our National Art Museum. I have had the advantage of seeing most of the collections in Europe, north of the Alps, and am free to say that, as a typical collection of caskets, coffers, and marriage chests or *casoni*, the South Kensington examples stand first. I do not refer to what are called cabinets, in which, so far as value and variety are concerned, the Green Vaults at Dresden must carry off the palm. But I am forced to agree here also with M. Labarte, in his opinion that many of these pseudo-architectural productions are, after all, but elaborate artistic follies. For art, value, and guidance, I think we have reason to be satisfied with our own national collection; and I am happy to be able to refer to some of them, which have been kindly lent for the occasion.

One of the most interesting examples is an ivory carved box (10-66), with silver frame and mountings of decided Byzantine character, believed, with good reason, to be the work of the 10th or 11th century. It is oblong in form, with feet, and a lid resembling a penthouse roof in character, and the body following the Mosaic proportion generally, $2\frac{1}{2}$ by $1\frac{1}{2}$ by $1\frac{1}{2}$. The surface is in bas-relief, almost flat, but the ground is cut down very deeply; thus giving an effect of unusual boldness and force.

The only pieces which came near to the nature of caskets, produced about this time in Western Europe, were oblong shrines or really boxes, having pointed gable lids similar to the roofs of the ecclesiastical buildings of the period, and made to contain what were held to be the most precious treasures of the Church. These were the reputed relics of the greatest saints of old, and hence the name *chasse* was given to the smaller boxes, while the term shrine was retained for the larger ones. One of the earliest and finest of these is the "Shrine of the Magi," in Cologne Cathedral, which dates from the 11th century. The front is surrounded by a border of gold, decorated alternately with precious stones, *en cabochon*, and enamelled ornaments in gold filigree. A series of arches decorating the sides are each cut out of a single plate of metal, decorated with *champ-levé* enamels. A very fine enamelled shrine of the 12th century, in the Soltykoff collection, with subjects representing the entombment and the resurrection, deserves mention; while a beautiful enamelled *chasse* of the same period in the British Museum, the subjects represented being the Virgin and Child, with apostles; should be examined, as a remarkable specimen of the time.

I am fortunate in being able to show one of these religious caskets (7945-62). The shape is the usual one, with a high ridge roof, the enamels are on copper, and the figures are of

* "Arts of the Middle Ages," c. vii.

the usual treatment, though it is difficult to fix the date of its execution.

We are now approaching a time when the secular casket, as such, began to appear. The dower of a lady of the Middle Ages was often enclosed in two boxes of very different sizes. One was large, of bold and often beautiful proportions and called *casone* in Italy, *bahut* in France, and chest in England. These contained the dresses and larger valuables of the lady's wardrobe. The smaller box, called *coffret* in France and casket in England, held her jewels, money, and treasures which lay in small compass. This is illustrated in the words of Shakespeare, "I have writ my letters, casketed my treasure, and given orders for our horses." These caskets were often of wood or ivory, charmingly carved, of wood covered with gold, silver, or brass; wood with decorated leather, at times silver and gold, lastly, of iron or steel.

A carved oblong box of maple wood (1167-64), with severe Gothic arches and panels, boldly cut, marks a transition period. It is said to be German work, probably of the 14th century, and is so ecclesiastical in spirit that it is difficult to say if it was originally a lady's casket, or an *armoire*, a name given in France to treasure boxes of the church. Another casket (176-66), with panels of bone of shape well-defined and boldly divided, is carved with events from the life of the Virgin, also Gothic in panels and arches, but the style is more free, and the box is more clearly intended for a lady's jewels. The date is about the 15th century. Another casket, Italian, of the same date, is one of the treasures of South Kensington Museum (706-1884). It was purchased from the Castellani collection at a cost of some £500, is of silver, parcel gilt, with sloping lid, oblong in general form, with four small feet; its chief glories being a series of quatrefoil plaques in translucent enamels, upon figure groups embossed in low relief, and the details afterwards engraved after the method described by Cellini*. The subjects are scenes in the life of the Saviour, of the Virgin Mary, and Saints. These enamels, which give so much value to this piece, have lately been reproduced as to their essential character by Falize, of Paris.

Let us now turn to another type of box, less ambitious and costly, but, withal, marked with much feeling and style. It is of wood covered with leather (2180-55), *cuir bouilli*, is oblong in shape, enriched with incised patterns in low relief, a leading shield of arms, and Latin and Italian inscriptions; the date is given as 1490. There is also a larger *coffret*, leather-covered (898-1877), decorated with Scripture and hunting subjects, which is interesting, and deserves examination.

There is a curious casket (2168-55), stated to be of the 14th century, but which cannot, I think, be much earlier than the period at which we have arrived. It is oblong, of wood, covered with stamped and gilt brass work, having rosettes, heads of queens, and sphinxes, in alternation, showing much effect and colour, the surface being varied and rich. It is bound with twisted brass bands and clamped, so that the necessary strength is not lost sight of in the search for decorative beauty.

We now come to the iron age in caskets—the time when it was requisite to take more precautions than formerly against theft and violence. This iron age may, indeed, probably have begun at a much earlier period than the authentic examples left us would indicate. They were also used, as we learn, by nobles and knights, no less than by the fairer sex. M. Viollet le Duc informs us*—"During their journeys ladies carried them with them, and kept their jewellery in them. In the country, in distant expeditions, the nobles and knights, besides the trunks which contained their effects, took these caskets, which were confided to the charge of the squire, and contained money, jewels, and sometimes even title deeds; for it was no unusual thing, even up to the 13th century, to carry about with one family papers and important deeds."

While, then, the richly carved ivory box, the jewelled and enamelled casket, were most appropriate for fixed positions in the hall or castle, the iron casket, with its strength and elaborate lock, was more suitable for travel and dangerous service. There is a typical one in South Kensington Museum, which combines strength with beauty (87-65). It is of iron, oblong, having an elaborate lock on lid, and was made in Augsburg about A.D. 1530. The form is excellent, having a raised moulding on lid to protect the lock-plate, with gilt metal corner pieces, while the general surface is finely engraved with winged unicorns and arabesques. There are great numbers of these iron caskets, of uncertain dates, in museums. Messrs. Hardman, of Birmingham, exhibited one in 1862, of which I have an

* "Trattato dell' Orificeria." Milano, 1811, p. 45.

* "Dictionnaire raisonné du Mobilier Francais."

illustration. It had an arch top, with handle on lid, was appropriately decorated with rose-sprays, and parcel gilt. But Messrs. Chubb have probably come nearest to the mediæval idea, with their drawing-room safes opened by golden keys.

From iron we pass to bronze. There is a charming little box (2084-55), bronze gilt, arched at top, and handle as last described, with arabesque ornament in relief, and the legend of Orpheus given in panels, which leads us to less troublesome days. To show how long the strong box idea lasts, however, there is an interesting example of Dutch 18th century work (1130-1864). It has a curved lid, strong lock, hinges, framework, and angle-plates in brass open work, the panels, however, being much contrasted by being made in cane wicker plaiting.

There is also a very fine and characteristic box, English, of the 17th century (619-1890), which I should not omit to refer to. It is large, oblong, with lock and handle at top, is of wood, covered with brass *repoussé* work, roses, tulips, and trefoils, bound with iron, and studded with nails, the whole surface work being artistic and appropriate.

We will now take a step southward, and regard for a few moments the Italian marriage caskets of the Middle Ages. These caskets are of wood, ornamented with pounced patterns, and covered with most minute and beautiful subjects, figures, foliage, and ornaments in fine paste or stucco, probably the work of Francesco l'Indaco or his followers. Of these works in *gesso-duro*, South Kensington has a series, and the one I have noted is a typical example (110-1887). It is oblong, with sloping lid, the panels having raised figures, in processional groups. Gifts, music, &c., probably marriage offerings, are shown on the lid, shields of arms in positions of vantage. The *gesso-duro* is white upon blue and gilt grounds, and the legend, *Omnia vincit amor*, is shown on a painted riband on the centre panel of lid. While referring to Italy, it may be well to observe that the motive of the wood casket, richly carved, gilt, painted in imitation of enamels, and of massive, oblong form, has been retained until the present day. A fine example of this is the jewel casket of the late Cardinal Antonelli, exhibited in 1862, and of which I have an illustration. It was executed by Fiorentini, of Rome; at the base are lion supports, and the four great prophets; at the angles are figures of the twelve apostles, each corner has a statuette of one of the evangelists. Allegorical figures adorn the panels, the centre one containing the Cardinal's arms and insignia. The rich foliage of the cover is in open carved work, over which is a seated figure of religion on a lion-headed throne, and holding the keys of S. Peter.

We are told of the immense number of caskets of great value and beauty, produced by the Limoges enamellers as early as the 11th, 12th, and 13th centuries. I have before referred to the ecclesiastical ones, but for the lay caskets I fear we must go to a later period. The example from South Kensington, of uncertain date, illustrates the style (1440-'55). It is oblong, ebony and gold, with five enamel painted plaques, of the modern Limoges type, which I need not further describe. The charming little silver box, of classic type, lent me by Mr. Camden Piercy, has a series of enamelled panels of Roman subjects, probably of a not much later period; while a silver open-work box, from the same collection, may carry us to the 18th century. We then come to the time of the Battersea enamels. Caskets, painted in delicate colours, with views, flowers, fruit, and foliage, are not infrequent in collections of this ware.

A notice of caskets would be seriously incomplete did it not refer to the famous ivory and metal workers of the far East. Arabia, Persia, and India have been so long famed for their productions, that there must be many of the highest lessons to be gained by a study of what the wrecks of time have left us. Firstly, the Arabic motive seems quite different from the European. The box is of metal, damascened; it is quadrilateral in plan, with sides sloping towards the top and sloping lid, the feet being in line with the box. A very precious example is at South Kensington (459-1873). It is in brass, covered with silver plates, chased with foliage, birds, and human-headed lions, inlaid with gold, also with geometric designs and Arabic inscriptions, carried out in superb style and finish. It has silver chains to support the lid when open, and Mr. Purdon Clarke considers it is Mosuli work, perhaps as early as the 13th century.

Modern Persian work reverts to the oblong box, as a rule. A box with falling front and fittings, as a cabinet (1090-'75), is richly inlaid on wood, after the Persian manner, with figures, animals, and foliage, the materials being vari-coloured pieces of ivory and brass wire. A more ambitious box, probably dating from the commencement of the present century, and covered with Shiraz mosaic, the lid being

brass, and having a border pierced and engraved with figures, and Persian inscription, is inlaid charmingly with silver, and prominent lines of border are decorated with turquoise and garnet.

I learn from my friend, Mr. C. Purdon Clarke, who has given so much study to Oriental art industries, that the usual jewel-box in India is circular, carved and decorated, in which, also, perfumes and other toilet requisites are kept. As to the ancient Indian casket, one of the best examples we have (8495-'63), and which I am fortunately able to show, is curiously related, in shape and character, to the ancient Byzantine one, to which I have already referred. It is ivory, oblong, with pent-house lid, and an ebony slab, which is an ugly late edition. Like the former one, it is constructed with bold ornamental divisions, the plaques of ivory between being very boldly carved with grotesque human figures, curiously squeezed into the panels. The nails are shown with commendable frankness, and the two caskets are well worth studying together.

A modern Cingalese casket (38-'68) is again, with its arched top, curiously related in shape to the ancient Italian *casone*. The ivory openwork ornament is, however, very refined and harmonious, showing against the darker wood back-ground in a very interesting manner. The carved monsters and foliage appear to betray a European influence, but the treatment is all that need be desired.

After roaming among historic records, and reviewing from the fragments that remain to us the art work of so many nations, it is a confession that one may perhaps make with some equanimity, that the address casket, strictly such, may be styled a feature peculiarly English. After some little research into the habits of the past, it is noteworthy that history seems eloquently silent as to a custom of presenting addresses in a box of some precious material or artistic construction. I was especially interested, in 1878, in examining the wonderful collection of ancient art treasures in the halls of the Trocadero at Paris. There were many superb specimens of caskets, but none that appeared specially designed to enclose addresses. We must not forget the wholesale destruction of art treasures by Louis XIV. at the latter part of his long wars against the Allies, nor the melting down by Louis XVI. of the contents of the treasury of St. Denis, which M. Philippe Burty describes as a calamity for art, as great as that of the burning of the Alexandrian Library was for literature. Still the fact remains, and it is a singular one. As a member of the Jury at Paris, in 1889, I had special facilities for examining the goldsmiths' work, in what was perhaps the finest Exposition of modern work the world has yet seen. But in that display I do not remember a single Continental example of a casket produced to receive an address. So far, then, we have a claim to believe that the system is of English origin.

The custom of bestowing the freedom of a city is of very ancient date, and I may be excused from giving details of it here. This freedom, usually obtained by service, was given on a parchment certificate, signed by the chief magistrate, and enclosed, usually, in a cylindrical box of box-wood, much after the style of a needle case, in which it would closely fit when rolled. But when a city became rich and powerful, it was in a position to confer distinction upon men who had deserved well of their country, by offering to them the honorary freedom, and enrolling their names on the list of its citizens. The occasion was one of great ceremony, and it would naturally be felt that the ordinary boxwood "pyxis" would be quite inadequate for the purpose. So a more elaborate box was provided, which has gradually developed into the modern address casket. The city of London appears to have set the example in this respect; but it is unfortunate that its records are so meagre, and that early tabulated accounts have been destroyed. Further research may bring to light much important information, but a systematic statement in the Chamberlain's office commences with the year 1740. From this, it is clear that the practice of giving the honorary freedom of the City to eminent persons was in full swing, as also the custom of enclosing it in a gold casket. Thus, in 1740, Vice-Admiral Vernon was presented with the honorary freedom in a gold box, after the victory of Portobello. William, Duke of Cumberland, had a similar distinction, after the defeat of the rebels in 1745; and William Pitt, afterwards Earl of Chatham, in 1757, at the close of his first short administration. The Right Hon. R. B. Legge was bracketed with Mr. Pitt for a similar honour; and so the list goes on at regular intervals. In 1767, Christian, King of Denmark, was singled out, on a visit to this country; and the gold casket is noted as having cost 200 guineas, a much larger sum, relatively, in those days than it would be esteemed now. Rear-Admiral Rodney received

a gold box from the City in 1780, on returning from his famous victory; and, in later days, Nelson and Wellington accepted these marks of respect and admiration from the City. But we get from the records the mere statement of the fact, and the money value of the gold caskets, with no description that would enable us to form an idea of their respective artistic merits.

There is one interesting fact in connection with these early address caskets which must not be omitted here. Charles Dibdin, the famous song writer, was, at the date at which we have arrived, in the vigour of his age, and near the summit of his reputation. We all remember the famous couplet in one of his patriotic odes,—

> "Our ships are made of oak,
> And hearts of oak our men."

Now, I must leave it to the learned to determine whether, in some one of the 1,400 songs this prolific writer produced, the phrase "hearts of oak" had occurred previous to the year 1779. But in that year, curiously enough, there was presented to Sir Augustus Keppel the first "heart of oak" box, embellished with gold. Whether the custom gave rise to the song, or the song to the custom, I have not been able to ascertain. But the custom became general, so far as the City of London was concerned, and continued for some sixty years. I have seen one of these "heart of oak" boxes. It was of a fanciful rococo shape, about the size of a club snuff-box; in fact, it was lined with burnished gold, and so exactly fitted to close air-tight, that it would well have served the purpose. The wood was of that delicate rich brown colour, finely grained, characteristic of the heart of the oak, and which does not seriously darken in a century. The lid was covered with richly carved rococo scrolls, the arms of the recipient in centre, and at sides were military trophies suited to the presentation.

In coming now to modern times, I am reminded of the fact that the reason why Chairs of Modern History are not more largely founded at our Universities, is because of the risk that the professor's views of recent events may be largely coloured by his political predilections. It is evident that similar risks are run by one who dilates on modern industrial art. Should he adopt a tone of caustic censure, he is liable to be reminded of Lord Beaconsfield's famous aphorism, that "Critics are persons who have failed in literature or art." If, on the other hand, he should indulge in exuberant praise of the objects under review, he may be asked the question "Who are your friends?" I must therefore crave your indulgence while I endeavour, on this subject, to steer between Scylla and Charybdis, simply premising that the examples have been drawn from as wide a field as possible. I can deal with but a few pieces; it is only safe to speak of those of which one has some knowledge, and I propose to suggest a few lines of thought for your consideration, rather than to set down a hard and fast dictum of praise or blame.

A casket presented to the Rev. T. Raffles, of Liverpool, after a pastorate of fifty years in that city, and exhibited by Messrs. Howell and James, at London, in 1862, has refinement of form and dignity of expression. It was designed by Mr. F. M. Miller, professor of sculpture at South Kensington. A much later one, presented to Sir Frederick, now Lord Roberts, after his remarkable march from Cabul to Candahar, was also produced by Messrs. Howell and James. It was in gold, oblong, with arched top, after the style of the Italian *coffret*, and the design, for which Mr. T. Buxton Morrish was largely responsible, included enamels and *repoussé* work, all having a strict regard to the subject. The handle at top, of constructive form, had entwined within it the initials of the General; his various decorations were arranged in a panel on obverse of lid, also in *champ-levé* enamel. Coats-of-arms, enamelled and enamel painted, occupied obverse and reverse of casket, while the ends were decorated respectively with views of the citadels of Cabul and Candahar; the architectural features treated with enamel lines after the mediæval manner. Trophies of Afghan and English arms, with suggestive symbols and Latin mottos, completed the decoration, while at the feet, of sound construction, dolphins were sporting. Mr. J. W. Benson had a distinct success in the casket made by him, as the City presentation to Sir Henry Bessemer. The figure of Invention, with the steel converter one side, and pigs of crude iron on the other, is sufficiently suggestive. The box is gold, a rich Renaissance, with bold decoration and twisted steel columns, while the plinth of steel, a *tour-de-force* of the inventor, is certainly realistic.

At this stage it will be convenient to refer to caskets which have ostensibly taken a distinct architectural character. The Italians of the 17th century were especially famous for caskets in iron, damascened in gold and silver. These caskets, of which a fine example is in the col-

lection of Earl Cadogan, partook of the character of the buildings of the period, being marked into divisions by pilasters or columns, having architectural mouldings and panels like window frames, so that the enamelled centres might almost serve for the stained glass. This style has reappeared in modern times, chiefly in caskets of a classical character. A notable example of this was the casket presented by the City to Mr. Gladstone, in 1882, and manufactured by the Goldsmiths' and Silversmiths' Company, of Regent-street. The severe lines of the box were suggested by the classic tastes of the then Premier; the centre trophy, of Mr. Gladstone's heraldic bearings, was approached on either side by a series of figures in gold against a field of blue enamel, which gave unity and symbolic value to the attributes represented. Four figures beyond the casket expressed qualities held to be exemplified in Mr. Gladstone's statesmanship, and the lid was elaborately decorated by emblems, in which the bust of Homer and the Lamp of Learning were conspicuous. *Punch* probably served the makers most, in regard to this casket, with humorous description, full of point, one of his sallies being to the effect that the Tuscan columns at the sides represented the columns led against the Government of the day by Mr. Parnell, on the one side, and Lord Randolph Churchill on the other.

An important casket of this class was produced by Messrs. Elkington, as a gift from the city of Athens to the Crown Prince of Greece, on the occasion of the attainment of his majority. It was designed under the direction of his Excellency M. Gennadius, Greek Minister at the Court of St. James. As a classic purist, he desired that it should represent the spirit of the famous city, and this was done with scrupulous accuracy of detail. On the lid are statuettes, the prince himself in centre. On the right, the city of Athens, presenting the address, while Pallas Athene, panoplied as of old, looks on approvingly. Altars of science and art respectively are at each side of the group. The "labarum" of Constantine is seen in front, with the arms of the ancient city. The box itself, having Corinthian columns at corners and ends, has a remarkable bas-relief. In centre, beneath a classic doorway round which is bending a growing laurel, in delicate compliment, the prince is seated. On either hand assemble the various provinces of Greece with messages of congratulation. Theseus, Achilles, Constantine, and Alexander each play their part in the design, and the surface, diversified with gold, silver, and rich enamels, gives the whole an effect of pure and balanced colour. Another casket, also by Messrs. Elkington, presented to the prince—this one by Greek residents in England—yet more emphasises the architectural idea. The figure work is elaborate and appropriate; not the least so being the panel where the Goddess of Wisdom, disguised as Mentor, is instructing the young prince in the duties of life and the art of wise administration. I must pass on to a casket from the same house, designed by an architect of Wigan, the motive being suggested by the ancient Town-house, supported on columns, a specimen of Early English construction. The arrangement is ingenious and decorative, the summit being crowned by a figure of the borough progress—based on coal—the miner's lamp indicating one stage, and the electric light the other.

In the year of Jubilee of Her Majesty's reign many caskets were presented, some retaining the architectural motive, while others were marked by much boldness and freedom. The one from the borough of Leamington, supplied by Mr. T. R. Roberts, in ivory and gold, was oblong in form, graceful in line, and the ornament agreeably disposed. A casket manufactured by Messrs. T. and J. Bragg, and presented to Mr. Peel, son of Sir Robert Peel, on the attainment of his majority in 1888, is a typical instance of an oblong box of ivory, decorated with gold and silver, following, in many respects, the traditions of the Middle Ages. The lid, rising in a gentle curve, is surmounted by a boldly modelled and enamelled blazon of the arms of the Peel and Tweeddale families; at the sides are enamelled portraits of Sir Robert and Lady Emily Peel, the father and mother of the recipient. Around central monograms, on obverse and reverse of lid, are *repoussé* panels, referring to agriculture, arts, and commerce. The motive of the design of the box is the family motto, "By Industry," and as a model by which it is gently suggested that the young man should shape his future career, a statuette of the great Sir Robert Peel, reduced from the statue in the market-place at Tamworth, is placed in a canopied arch in centre of casket. On either side of this, in gold frames, are enamel painted views—one of old Drayton Manor, the early home of the family, the other of the present mansion. The Tamworth arms and other relative subjects decorate remaining sides of the box; and the statuette of the great Prime Minister is saved

from apparent isolation by four other figures to same scale, occupying corners of the casket, having reference respectively to agriculture, the industrial arts, and wise and just legislation. Another casket, in gold and enamels upon a box of ivory, presented to the late Duchess of Sutherland by the ladies of Torquay, after a lengthened visit of the Princess of Wales and her three daughters to that charming place, was also manufactured by Messrs. T. and J. Bragg. It was oval, with arched ends, the lid raised up in several lines, the Princess's coronet surmounting it. The treatment was light and graceful, the leading features being four portraits, enamel painted on gold, of the Princess and her daughters, one forming the central motive on each side of the box.

We must not fail to describe the superb casket presented last year by the city to the Emperor of Germany, and manufactured by Messrs. Mappin Brothers. If anyone desired to form an idea of the extent to which the casket conception had developed during the past hundred years, it would be gathered by a comparison of the heart of oak box, or club snuff-box of a century ago, with this fine example of goldsmiths' work, which I will shortly describe. The style is that of the free Gothic of the Guildhall itself, which is adopted with brilliant effect, the open arches and tracery being shown against royal blue enamel, while the continuous borders and deep panels give a richness of colour quite remarkable. The shape is oblong, with semicircular bays at either end, the upper moulding is supported by a band of Gothic capital enrichment, and is crowned with a royal coronet border, similar to ancient boxes just referred to. A splendid feature at the base is a series of blazoned shields and ribands, giving the arms and names in a series of all the different kingdoms and duchies included in the German empire. Imperial eagles appear over the coronet rim; the arms of Germany occupy the centre; four emblematic figures in *repoussé* express the wishes of the City for the peace and progress of that empire, in fraternal union with England, and two interesting events connecting the two nations are displayed on the semi-circular bays. One is the marriage of our Queen with the late Prince Albert; the other the marriage of the late Emperor Frederick to the then Princess Royal of England. On the lid is the seated figure of the City of London, her mural crown being decorated with the wings of the dragon crest, a wealth of merchandise about her, the *caduceus* of commerce held aloft in the right hand, the City shield supporting her left.

In closing a description of various classes of address caskets, with which I hope I have not wearied you, let me remark that jewel caskets, as such, have followed much the same lines of change. The forms have become richer, bolder, and less conventional, not seldom, I fear, trespassing beyond the limits of the true rules of art. In gold, silver, damascened work, as well as in less costly materials, they vary so much that it is difficult to fix a modern classification. We may take two typical ones, both by the Messrs. Elkington. One, by M. Willms, is severe, classic in form, oblong, with pilasters at angles, and bas-relief in *repoussé*. One side represents a wedding procession, another the Athenian marriage ceremony. The doves of Venus and figure of Cupid on the lid, with the torch of Hymen, sufficiently indicate the object of the casket to be that of a bridal gift. The other low, long box, designed and modelled by the late M. Morel Ladeuil, is charmingly unconventional and free in treatment; while the placing of the figures to occupy the corners suggests the master hand.

I have finished my parable. It is a long stretch, from the first historic box overlaid with gold and containing sacred symbols, to the gold casket offered to an Emperor by the richest City in the world. There are many intervening stages, all of them interesting, although the most precious examples have been destroyed. The lessons they teach us are of patient art industry and laborious achievement. The works of the past bear no marks of haste upon them; their minute surface detail always speaks of leisure and reflection. In our modern days we have changed all that. Design, model, finished work, all must be completed in hot haste. What wonder if, in this rush and hurry, we lose something and forget much. The patient, loving care with which the artist of old could dwell on the minute parts of his design, the thoroughness with which he could adapt one part to another in those old days, gave him advantages which we are liable to miss in modern work. Knowing, as I do, the conditions under which large and elaborate presentation pieces are now got out, I do not marvel that they are not better; I often am surprised that they come through the race against time so well as they do. Partly for this reason, and still more because of the lack of art education among our workpeople, there is much modern work in this

class, which I prefer not to name. Pieces in which the decoration seems thrown together by accident, and in which different styles jostle each other, like fares in an omnibus—blatant vulgarities, that sin against every law of taste, and which are only remarkable for the unblushing audacity with which they violate the canons of art. These, unhappily are the products of 19th century competition.

Let us draw a veil over these infirmities, so far as the past is concerned, but let us, each in our own sphere, do something to provide against their prevalence in the future. First, let us educate our workmen, that they may be able to give the loving, artistic touch, and to afford the delicate sense of finish, which must add the final grace to the conception of the designer. Next, let us remember that a work of art must have time for its successful production. It is all very well for the contractor to tell us of five railway bridges being built in a fortnight. This is only a question as to how many men are needed to lay so many bricks, to cut and place so much stone. But, if you desire a work of art, and not a mere contract piece of no art value, you must give time for the hand, and heart, and brain of the artist to do their best upon it.

Again I would lift my voice against the miserable system of competition, which makes of what ought to be a work of art a mere race for advertising purposes, and often means a heavy fine upon the successful competitor for the privilege of putting his name to the piece. It is wonderful, under the conditions which often prevail, that great houses will be so public-spirited as to give so much real art at their own cost in important presentations; but surely it is not a healthy sign that they should be placed in such a position.

Lastly, may I add that it is well to guard against the rush for mere novelty of form in these caskets. The rage to secure a new shape often leads to most barbarous results, and while, I trust, I am the last to desire a dull and barren uniformity, I would remind my hearers that eccentricity is not always beauty, and that many a design which possessed excellent features has been incurably marred by a painful striving after some unheard-of effect. A beautiful design, whether of a casket or anything else, always has the virtue of repose. It appears brought together without effort, and you feel that you cannot take any part or ornament away without injuring the effect. Some caskets I have seen have hardly a single ornament which has a sustained attachment, and we might say of its decoration, remove it altogether. Unity of form and harmony of colour are most essential; and when to these are joined a sound conception, just construction, and artistic treatment of detail, we have the jewel and address casket, worthy of the knowledge and executive ability which, undoubtedly, exist among us.

With these remarks, and trusting to be favoured with the views of a Society which numbers among its members so many distinguished artists and experienced critics on a subject which is deeply interesting to me, I will now leave the paper in your hands.

DISCUSSION.

Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., having expressed his cordial thanks to Mr. Tonks for his kindness in preparing the elaborate and, historically, most instructive paper he had just read, said he had no special knowledge of its remarks on the primitive history of the casket. particular subject, and could only offer a few That was clearly revealed in India, where Hindu art to this day remained still hieratic and symbolical, and had, in none of its applications become secularised. It was evident to anyone who had been in India and studied the religious art of the Hindus, and the ideas it typified—ideas suggested by the frankest recognition of the more obvious physiological facts of our common human nature, the Divine and miraculous character of which has never become dimmed in their unjaded eyes—it was obvious to such a person that the casket of the myth of Pandora referred to woman herself as the human embodiment of the reproductive or maternal principle of nature. The story of the consecration of the young Nero's beard had a similar significance to the practice still prevalent in some parts of this country of stuffing a handful of hair, plucked from a new-born calf, into the left ear of its parent-cow. It symbolised the consecration of the first fruits of his adolescence to the maternal deities, *i.e.*, the reproductive principle, and thus symbolically realised his completed institution as a man. The first casket, universally, is woman; and the second is the place of human sepulture; a hollow tree, as still in Tasmania, or a portable ark of wood or metal, or a natural cave, or an excavated rock, or hole dug in the ground, or an earthenware jar, each and all symbolical of the mother* that bore the dead one into the light of life, and gradually of the resurrection of the body, the regeneration of the soul, and the everlasting life to come. The last, greatest, primitive casket was the shining frame of the heavens, bound in by the

* The hollow "Mother Tree," of popular superstition, and "Dame Holda's Tree of Germany," has frequently, in Europe, become transformed into a chapel to "Our Lady," the Blessed Virgin Mary of the Christian Church.

twelve signs of the zodiac. This was represented either of a cubical form, in which similitude of the heavens, the *Kaaba* at Mecca was designed, or sex-sept, oct, dec, or dodecagonal, or globular.* Caskets of the zodiacal type were still made in India and in Burmah, in which latter country indeed the primitive symbolism underlying Indian art could often be better studied than in India itself. Except that there were the twelve apostles for the twelve signs of the zodiac, and the four evangelists for the four guardians of the four quarters of the heavens, and an unmeaning finial to it, one of the caskets exhibited by Mr. Tonks might almost be said to be a direct transcript from a Burmese one sent to the Colonial Exhibition of 1886. It was surrounded by the twelve signs of the zodiac which stockade the universe, and was protected at the four corners by the four guardians of the four quarters of the heavens; while the lid was surmounted by a lotus bud, symbolising the generative or paternal principle of nature. Such a casket has exactly the same significance as the ark of the heavens, and the seven-nailed horse-shoe, which last represents the vault of space, with its seven active principles of life, *i.e.*, the seven planetary bodies known to the ancients. Similarly, the heavens have always been represented in the East by a seven-branched tree, a four-square city, a holy mountain, and a virgin mother; and we have all this imagery concentrated in the *Revelation of St. John the Divine*, and in a manner that seems directly suggested by decorative designs extant at the time it was written.† In India a Hindu woman's toilet-box always contains an iron symbol referring to her husband with very *naif* realism. These facts are clear indications of the primitive ideas that form the basis of all natural religion, and which permeated the pagan art of Greece and Rome, as they still permeate that of the Hindus. Everyone knew the etymology of the name of Delphi, and the significance of the Omphalos enshrined there; and to this day in India every hollow place is regarded as sacred to the divine mothers, and every hill to the divine forefathers of the human race. He would not attempt to criticise any of the modern caskets exhibited. They were beneath contempt. They violated every principle of utility and beauty, and made no pretence to express the primitive ideas and archaic myths that had first suggested them to the jewellers' art. It was an abuse of language to talk of them as illustrations of development from the mediæval examples lent for the illustration of Mr. Tonks' lecture by the South Kensington Museum, unless the word was to be understood in the sense also of retrogression and degradation. It was impossible to look at some of the more elaborate recent examples with any patience, and the manufacturers' self-complacent descriptions of them were enough to give one the nightmare.

Colonel LAMBERT agreed with the last speaker, that some modern specimens were more like nightmares than works of art; at the same time, he agreed with Mr. Tonks that you ought not to expect a manufacturer to put his hand in his pocket and produce an article worth twice or thrice that which he was to receive for it. It would be more satisfactory if the names of the designers of these boxes were associated with them rather than the names of those who sold them.

Mr. A. WYON said public competitions did a great deal to prevent the highest art being put into the work. It was manifestly unsatisfactory to give such small sums, when so many competed who got nothing at all for the artistic work they put into the competition.

Sir PHILIP MAGNUS said he had never been presented with a casket of any kind, and he had therefore no opportunity of studying the subject, but he had had the opportunity of seeing the very great interest which Mr. Tonks took in the production of artistic work in his own town, and was therefore attracted to hear this paper. He could not say anything about the caskets of the past or of the present, but he might say that those of the future would be much better than some of those of the present, if Mr. Tonks's ideas on art training were carried into effect. Mr. Tonks had taken a deep interest in the organisation of one of the most practical schools for improving art work, with which he was acquainted—the School for Goldsmiths' Work in Birmingham. Mainly, through his agency, two or three hundred young artisans were gathered together in a branch of the splendid Art School of Birmingham to learn the principles and practice of the art which specially applied to their own trade. They learned drawing, designing, and colouring, in their application to goldsmiths' work, and had the opportuuity of practising what they learned in the class in which chasing, enamelling, and mounting were also taught. He could not doubt that such splendid practical instruction would have a decided effect in improving the art work of the future.

Mr. LEWIS DAY said that, as he listened to the paper, and looked at such of the drawings of the old work as he could see from where he sat, he could not help thinking how impossible it would be to prevail on any 19th century committee to approve of any such design. There was great talk about improvement in art, and how it could be effected, but one of the

* The "Ciborium minus," or pyx, used in the Catholic Roman Church for holding the Blessed Sacrament, is directly derived from the *argha-patra* casket used in Hindu temples for holding the lapilliform *lingaw* of Siva; and from it are also derived the censer used in censing the images of Buddha in China and Japan, and the secular rose sprinkler used at ceremonial receptions by the Persians and Indian Mahomedans. See *Journal of Indian Art*, for October, 1891.

† It is almost certain that the "Throne of Satan," of the *Revelation of St. John the Divine*, refers to the "Great Altar," sculptured with "the Wars of the Giants," at Pergamon.

chief difficulties in the way was not merely the hurry and competition, to which Mr. Tonks had alluded, but the committee. The committee, he imagined, was a comparatively modern institution. It consisted, ordinarily, of a multitude of councillors, who seldom agreed on the choice of anything worth doing. He would express no opinion upon the modern designs exhibited, but, referring to the casket-shape, he considered the departure from the original cylindrical shape a departure from the right direction; if the thing was to contain a presentation roll, the square box was less appropriate than the cylinder, and the architectural design still less appropriate than the box. That was possibly not the fault of the designer altogether; they had to reckon with the committee; and what they wanted was not art, but a toy.

Mr. C. Purdon Clarke, C.I.E., said his views were so strongly in favour of the old caskets, that he would say nothing about the modern ones. One of the old ones shown that evening was exceedingly interesting, as they had been told, within the last few days, by a great authority, who had examined it closely in the Museum, that it was really of English manufacture; and they hoped to be able to trace its original owner, though probably the maker's name would remain unknown. Sometime ago Mr. Tonks asked him if there was any fixed shape for Indian jewel caskets, and he said they were invariably round; and this was, in the main, right. There were some boxes of an oblong form, but, as a rule, an Indian woman kept her jewels in a round box, generally stoutly made of brass, calculated to last a lifetime, with strong chain attachments, so that they might be fastened to the saddle in travelling. He had seen heavy chains on them in the North-Western Provinces. One of the caskets, made of basket work covered with heavy brass mounts, was very interesting; and there was another one of the same character, but about twice the size, in the Museum, which was well worth studying. It was curious, as showing how the most fragile material had been mounted with the same heavy metal mounts as would be used with strong wood or ivory.

Mr. H. Stannus said these meetings of the Applied Art Section of the Society were valuable, as giving an opportunity for the interchange of thought, and adding to the common stock of knowledge. He had been struck with Sir George Birdwood's remarks; and hoped to be able to preserve them in print. He felt it would be unbecoming in him to depreciate modern work, though he must say that he thought putting these examples of the old by the side of the modern did the modern work great disservice. In the design of a casket, the material was important. When it was wood or ivory—the wood being necessarily framed up, and the ivory in small pieces—straight forms were obviously the most perfect and suited to the material; but when using metal, which was fashioned chiefly by beating up a plate, curved forms appeared more suitable to the material. Hence a wood casket in a curved form, whether carved or plain, would be wrong; and on the other hand, a metal casket imitating the straight forms of wood was equally wrong in the other way. In one metal casket, anyone could see the lines were not perfectly straight, and they were not so good as they would be if the material were wood. The ornamentation was the next consideration; and this might arise from two main motives: either from the desire to make the object beautiful, or from the desire for storiation—a decoration which told a story. How could that be done? Taking one of the examples before him, there were the arms of England and the portrait of Her Majesty; the story told was that it probably belonged to her; and if one went further into the decoration, there was something showing the date at which the casket was produced, and the circumstances under which it was given to her. This was a most interesting question: whenever an artist had to design a casket, he should take care that the ornaments upon it should not be merely decorative, but that each should have reference to the purpose for which it was made. Heraldic badges were of use in this way; or, again, the design might have something connected with the local associations of the place. The casket represented in one of the photographs standing upon eight legs, very much astonished him, until he heard its origin; and then, when he found it was made for the town which had its old-fashioned Market-house supported on columns, he saw the local associations, and recognised its appropriateness. There were others, designed like Greek architectecture. He did not propose to enter into the question whether the imitation of architectural monuments was desirable; but, if it were so, anything to be presented to a Greek prince might be of Greek character. He thought also that a great distinction should be made between the two kinds of caskets dealt with. Mr. Tonks had spoken about jewel caskets and address caskets; but they were by no means the same thing. An address which was rolled up should be put in a casket which suggested the form of the roll, as Mr. Day had said, whereas jewellery was in small pieces, and would go in any convenient shape. All those which were shown might do for jewel caskets, but none suggested an address casket. Obviously, again, a jewel casket should suggest the idea of safety; but not one of these modern ones gave that idea. Some did not even show that they had a lid; and at the back, where the hinge should be, it had not been made a part of the artist's design. Every artist designing such a thing must realise the data before him. The drawings showed the front; but he wanted to see how the hinge and the lock were dealt with. Those were questions which appealed to the practical artists; but the committees, generally, did not think of them; they wanted plenty of gilding and enamelling, and a velvet stand for their money.

Mr. LONGDEN said he knew nothing about caskets, but he thought those made in recent years were not as well designed as they might be. It was quite possible he had not been much in the way of seeing them, but they usually appeared to be a heterogeneous mass of emblems set in a florid manner. But there had been one piece of work done—not a casket, but for presentation—within his memory, which showed how work might be done. Most probably those present had seen the piece of plate given by the Officers of the Army to the Queen on her jubilee. That was made by Mr. Alfred Gilbert, and any one who had seen that, and had seen the pure originality of the design, and understood the use of the materials and the way they were combined, would say that as good work as was done in old times could be done now, and would be done if the same means were taken. The means were to find the artist and go to him, not to an "eminent firm," but to an artist, and let him do it. Give him a commission, and do not have a competition amongst half a dozen artists.

The CHAIRMAN said he wished first to refer, for a few moments, to the specimens which had been taken out of the cases at the Museum for the purpose of illustrating the paper. That had been done because, at South Kensington, they looked on the Society of Arts as their parent, and he thought the Society had reason to be proud of such an offspring. The Museum had one of the finest collections in the world, and he was not the only one who said so, and that Society, which took such an interest in the first Exhibition of 1851, as it had in others since, had had a great deal to do with the formation and foundation of South Kensington. Therefore, it was that the authorities were quite justified in making an exception in favour of the parent society in lending these objects of interest, the more so, when they were illustrated in such a practical way, as they had been, by Mr. Tonks. He was very glad that Sir Philip Magnus had brought out the very valuable work which Mr. Tonks was doing in the teaching of workmen at Birmingham. He was a practical man, and also a modest man, or he would have said something more about himself. On the occasion of the Princess Beatrice's marriage, it was arranged that she should receive a fan, which had been painted for her by the students of the Royal Female School of Art; and it was supposed that this would have to be sent to Paris to be mounted; but that was so foreign to his ideas, that he obtained permission to send it to Birmingham, where it was mounted by Mr. Tonks; and he would back the mounting of that fan against any of modern times to be found in Paris. If Englishmen would only have some belief in themselves, and, instead of always going to Paris, would promote designing in England, which was dying out because it was not properly encouraged, it would be far better. It was a horrible mistake, when some of the best designers in the world were our own countrymen, that people should always go abroad to get their ideas carried out. It was not natural, and not patriotic; and he did hope the time would come, when manufacturers would believe in themselves, and in designs executed in this country. He concluded by proposing a hearty vote of thanks to Mr. Tonks.

The vote of thanks having been passed unanimously,

Mr. TONKS, in reply, said he was quite overcome by the kind expressions made use of in regard to him. It was a great delight to him to open this question, but he was conscious from the first that as soon as he began a subject which always had been discussed, and probably would be for many a long year, it would show the deep chasm which separated ancient and modern work. They had heard many times of their great disparity, and in some respects he must agree with many of the remarks made, but still, at the same time, they must regard the influences at work, and, above all, the conditions in which they lived. How far those conditions could be improved was one of the problems for the Art Section to consider, and in that direction the discussions might be useful. Many of their friends no doubt looked to the past with very longing eyes, especially to the simplicity and severity of form, and the delightful decoration, which was hardly likely to be seen again until the artist had such leisure given to him as was given to the artist in one particular piece which he had described; but, on the other hand, they had to consider Committees, and all those people who were concerned, and the education not only of workmen, but of the public in artistic matters. Taking these points into consideration, it required much delicacy in dealing with modern work, simply on the ground that the defects arose very often as much from the tastes of the Committee as from the persons who might produce it; probably more so. In speaking of some classes of criticism, he was reminded of the figures on one of the Hamilton vases. There was displayed a Victory presenting a winner at the Olympian games with a laurel wreath, but there was also a person at the back pulling a feather from the wing of Victory. He supposed that was the Greek way of representing detraction, and perhaps a moral might be drawn from that for modern times. Mr. Stannus had referred to "storiation," and with that was connected the element of symbolism. How far it should be applied they had yet to learn, but it was an important element in modern art which ought to be more considered. Sometimes the most beautiful pieces of art were absolutely lacking in anything except that æsthetic sense derived from the delightful treatment of detail. He was not sorry that the time had gone when these pieces would be accepted by the public or Committees, and while they might admire much mediæval art work it was painfully lacking in that particular symbolic value. Even with regard to that beautiful piece described by Mr. Longden, he could not avoid saying that

unfortunately it was the basest rococo, of which style he had a perfect horror. He hoped he should not be accused of any lack of appreciation for the extreme beauty of Mr. Gilbert's work. His memorial to Mr. Fawcett was one of the most beautiful pieces of metal-work which could be imagined, and was not at all subject to the criticism he had now made. He hoped that great artist would not waste his time upon that corrupt rococo style, but that he would bring his great powers to bear upon a style much more worthy of his genius. The Jewellers' Art and Technical School of Birmingham was certainly one which was doing great good; while, not only in jewellery, but in every other industry, the City Guilds Institute, of which Sir Philip Magnus was Director, by their system of technical examinations, were doing a great practical work. The artist must go through the work if it was to be thoroughly artistic. How could you get artistic work unless the workmen were artistic? We should never, he feared, get to a time when the artist could follow his own work right through with his own hands. In some cases, where a very large sum was given, it might be done, but only in a few, and for the hundreds and thousands who wanted works of art it was impossible for the designer to work them out. In that case the only chance of getting back to perfect detail was to have educated workmen, who should carry out the ideas of the designer. The artist, therefore, in his own interest, should look to have a body of trained art workmen who could sympathise with his views, and, in course of time, would be able to interpret them. It was only by a combination of this technical and art training that there could be any hope of seeing again anything like the glories of the Middle Ages with regard to artistic detail of work.

Mr. J. HUNTER DONALDSON writes:—In discussing the interesting paper upon caskets by Mr. J. W. Tonks, I do not think sufficient reference was made to the beautiful collection lent by South Kensington Museum to illustrate it; and although disparaging remarks were made upon modern caskets, the differences between those and the ancient ones were not pointed out. There being no time to speak upon it that evening, I ask permission to offer few remarks now. Probably every person present would have concurred in the opinion that in beauty of design, suitability to their use, execution and variety of materials, the ancient examples were altogether admirable; but it was noticeable that whilst hardly any of these were exclusively of metal the modern ones were little else. It does not seem to have occurred to committees selecting such works that great artists of the past thought ivory, decorated leather, wrought iron, carved wood, and even rich embroidery, might effectually be employed in caskets; that the forms should be well defined, not overladen with emblematic and other details, or the sizes too small for their purpose. Competition being happily unknown, there was no necessity for the hot haste incompatible with the production of really artistic work. Now, why should such works be hurried? The city of London, for example, from past experience, knows very well that, in a given time, its "freedom" will be presented to some personage, and the sum usually spent on the casket. Why should it not at once invite artists to send in designs, the three best being paid for? On one being chosen, tenders for making it could be invited, subject always to the work being supervised by the designer, who, being free to employ the materials best suited to his design, would have a much larger number of skilled men to select from than are at present obtainable amongst goldsmiths only. Let us get rid of the vulgar idea that the casket is to be valued for the gold it may contain, and think only of the art in it which has made the South Kensington ones precious for all time.

The paper was illustrated by a series of fine examples of old caskets selected from the South Kensington Museum, and lent by the Lords of the Committee of Council on Education, as well as by some specimens exhibited by Mr. Tonks.

TWELFTH ORDINARY MEETING.

Wednesday, March 2, 1892; Sir FREDERICK BRAMWELL, Bart., D.C.L., F.R.S., Deputy-Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Gough, Kedgwin E. K., 1, Overton-road, Brixton, S.W., and Board of Trade, S.W.
Grant, William, University College, Gower-street, W.C.
Kapp, Gisbert, 31, Parliament-street, S.W.
Legard, Colonel James D., 13, The Cliff, Scarborough.
MacLean, Robert Black, Woodville, Burghill-road, Sydenham, S.E.
Scorgie, James, Poona-vllla, King's-gate, Aberdeen.
Scott, Ernest, 3, Investment-buildings, 67, Lord-street, Liverpool.

The following candidates were balloted for and duly elected members of the Society;—

Ellis, Walter L. J., 30, St. John's-wood-road, N.W.
Herschel, Prof. Alexander Stewart, M.A., D.C.L., F.R.S., F.R.A.S., Observatory-house, Slough, Bucks.
Parsons, Hon. Richard Clere, Oak Lea, Wimbledon-park, Surrey.
Sturge, Edward Brockway, 20, The Waldrons, Croydon, Surrey.
Wollaston, Arthur N., C.I.E., India-office, S.W., and Glen-hill, Walmer, Kent.

The paper read was—

THE SPONTANEOUS IGNITION OF COAL, AND ITS PREVENTION.

By Vivian B. Lewes, F.I.C., F.C.S.,
Professor of Chemistry, Royal Naval College.

Last autumn I had the honour of bringing before the Chemical Section of the British Association certain views, which are now widely gaining ground, as to the cause of the phenomenon of spontaneous ignition in masses of stored coal; and, in the discussion which ensued, Sir Frederick Bramwell expressed the hope that the paper would be followed by a second, in which methods for the prevention of this too often disastrous action might be discussed; and it is at the invitation of your Secretary that I propose to bring my views on the subject before you to night.

Ever since the general adoption of coal as a fuel, the storing and shipment of masses exceeding 2,000 tons has been recognised as requiring great care; and if much small coal has been present, or if it has been stored wet, firing, or at any rate heating, of the mass, has frequently taken place. On shore this has led to much inconvenience, and loss, but it is during shipment that the real danger has occurred; and many a fine vessel, with all hands, has been lost from this cause, without even a record of the calamity reaching the land.

In 1875, the loss of life and property from this cause became so serious, that a Royal Commission was appointed to report upon the possibility of preventing these appalling disasters; but the recommendations contained in the report, although of the greatest possible value, seem to have had but little effect in checking the loss from spontaneous ignition; and, in the nine years following the publication of the report (1873 to 1883), no less than 57 coal-laden vessels are known to have been lost from this cause, whilst 328 others were missing.

In coal stores, and in gas works, heating frequently takes place, but is so much more easily dealt with than at sea, that cases of absolute ignition are much rarer; and it is from the evidence obtained in the case of coal cargoes, that we can learn most as to the cause and prevention of this most dire plague of the coal trade.

In treating the subject to-night, I will first bring to your notice the explanation of the action which eventually results in combustion, and which is founded upon the work of Richters and myself, and will consider how the incipient action can be best prevented, or at least retarded, and the steps which should be taken in case ignition should result.

Coal is a substance of purely vegetable origin, formed out of contact with air by long exposure to heat and pressure, from the woody fibre and resinous constituents of a monster vegetation, which flourished long before the earth was inhabited by man; and coal may therefore be looked upon as a form of charcoal, which, having been formed at a temperature lower than that of the charcoal burner's heap, and under great pressure, is very dense, and still retains a quantity of those constituents which, in the latter case, are driven off as tar, wood naphtha, &c. These bodies consist essentially of compounds containing carbon and hydrogen, together with a little oxygen and nitrogen, and form the volatile matter and hydrocarbons of the coal.

Besides the carbon and hydrocarbons, coal also contains certain mineral bodies, which were mostly present in the sap and fibre of the original vegetation, and which gives the ash which is left behind when the coal is burnt. These substances consist chiefly of sulphate of lime or gypsum, silica, and alumina, whilst in nearly all kinds of coal is to be found a substance called disulphide of iron, coal brasses, or pyrites, which has been formed by the gradual reduction of the sulphates by carbonaceous matter in the presence of iron salts, and which, during the combustion of the coal, is decomposed, giving off sulphur compounds, and leaving behind oxide of iron, which gives the reddish brown colour to the ash of many kinds of coal.

Of these constituents of coal, the only ones which play no part in the phenomena attending heating and spontaneous ignition, are the mineral constituents other than the pyrites, and we have, therefore, to deal with the chemical actions which take place when the carbon, hydrocarbons, and brasses contained in newly-won coal come in contact with air and moisture.

A.—The Influence of Carbon in Producing Heating.

Carbon is one of those substances which possess to an extraordinary degree the power of attracting and condensing gases upon their surface, this power varying with the state of division of the particular form of carbon used. The charcoal obtained from dense forms of wood, such as box, exhibits this property to a

high degree, one cubic inch of such charcoal absorbing:—*

Ammonia gas	90 cubic inches.
Sulphuretted hydrogen ..	55 ,,
Carbon dioxide	35 ,,
Ethylene (olefiant gas) ..	35 ,,
Oxygen	9·25 ,,
Nitrogen	6·5 ,,

whilst certain kinds of coal also exhibit the same power, although to a less degree.

The absorptive power of newly-won coal due to this surface attraction varies, but the least absorbent will take up one and a quarter times its own volume of oxygen, whilst in some coals more than three times their volume of the gas is absorbed. This absorption is very rapid at first, but gradually decreases, and is, moreover, influenced very much by temperature, for reasons which will be explained later.

The absorption is at first purely mechanical, and itself causes a rise of temperature, which, in the case of charcoal formed in closed retorts, as in preparing alder, willow, and dogwood charcoal for powder making, would produce spontaneous ignition if it were not placed in sealed cooling vessels for some days before exposure to air.

The rate of absorption varies with the amount of surface exposed, and, therefore, able to take part in this condensing action, so that, when coal or charcoal is finely powdered, the exposed surface being much greater, absorption becomes more rapid, and rise of temperature at once takes place. If, after it has been made, charcoal is kept for a day out of contact with air, and is then ground down into a powder, it will frequently fire after exposure to the air for thirty-six hours, whilst a heap of charcoal powder, of 100 bushels or more, will always ignite. It is for this reason that in making the charcoal for powder, it is always kept, after burning, for three or four days in air-tight cylinders before picking over, and ten days to a fortnight before it is ground.

In the case of coal, this rise in temperature tends to increase the rate of the action which is going on, but is rarely sufficient to bring about spontaneous ignition, only about one-third the amount of oxygen being absorbed by coal that is taken up by charcoal; the action also being much slower, tends to prevent the temperature reaching the high ignition point of the coal. Air-dry coal absorbs oxygen more quickly than wet coal.

* Saussure.

B.—The Action of the Bituminous Constituents of the Coal in Spontaneous Ignition.

All coal contains a certain per-centage of hydrogen, which is in combination with some of the carbon, and also with the nitrogen and oxygen, and forms with them the volatile matter in the coal. The amount present in this condition varies greatly, being very small in anthracite and very great in cannel and shale. When the carbon of the coal absorbs oxygen, the compressed gas becomes chemically very active, and soon commences to combine with the carbon and hydrogen of the bituminous portions, converting them into carbon dioxide and water vapour. This chemical activity increases rapidly with rise of temperature, so that the heat generated by the absorption of the oxygen causes it to rapidly enter into chemical combination. Chemical combination of this kind—*i.e.*, oxidation—is always accompanied by evolution of heat, and this further rise of temperature again increases rapidity of oxidation, so that a steady rise of temperature is set up, and this taking place in the centre of a heap of small coal, which, from the air and other gases enclosed in its interstices, is an admirable non-conductor of heat, will often cause such heating of the mass that, if air percolate slowly into the heap, in sufficient quantity to supply the necessary per-centage of oxygen for the continuance of the action, the igniting point of the coal will soon be reached.

The effect of rise of temperature in increasing the rapidity of chemical actions of this kind can be realised from the effect which it has in the spontaneous ignition of oily waste or rag.

If a substance like cotton waste be rendered oily with anything except the mineral oils, it acquires the power of taking up oxygen from the air, and this oxidising the oil gives rise to heat. At ordinary temperatures this oxidation is slow, and, consequently, it may be days before the rise in temperature becomes sensible, but when this point is reached the oxidation proceeds with remarkable rapidity, and in a few hours the point of ignition is reached, and the mass bursts into flame, whilst if the oily waste be placed in a warm place at first, spontaneous ignition is only a question of hours, or sometimes even minutes.

Galletley found that oily cotton at ordinary temperatures took some days to heat and ignite, whilst, if placed in a chamber warmed to 130° to 170°F. (54° to 76°C.), the cotton, greasy

with boiled linseed, ignited in one hour fifteen minutes, and olive oil on cotton in five hours; and in a chamber heated to 180° to 200°F. (82° to 93°C.) olive oil on cotton ignited in two hours.

It has been suggested that very bituminous coal, such as cannel, shale, and coals containing schist, is liable to spontaneous ignition from the fact that a rise in temperature would cause heavy oils to exude from them, which, by undergoing oxidation, might cause rapid heating. But experiment not only shows that this is not the case, but that the heavy mineral oils have a remarkable influence in retarding heating; cotton waste, oily with easily oxidisable oils mixed with 20 per cent. of heavy mineral oil, being exempt from heating.

C.—The Action of Iron Disulphide, Pyrites, or Coal Brasses in Promoting Spontaneous Ignition.

The earliest theory as to the cause of spontaneous ignition in coal was, that it was due to the heat given out during the oxidation of pyrites (the disulphide of iron) into sulphates, and this idea has been adopted, and has held its own, in this country up to the present time, although the researches of Dr. Richters, some twenty years ago, clearly prove that the explanation was an erroneous one, and the late Dr. Percy, as early as 1864, pointed out that probably oxidation of the coal had a great deal to do with the action.

This disulphide of iron is found in coal in several different forms, sometimes as a dark powder distributed throughout the mass of the coal, and scarcely to be distinguished from coal itself. In larger quantities, it is often found forming thin golden-looking layers in the cleavage of the coal, while it sometimes occurs as masses and veins, often an inch or two inches in thickness, but inasmuch as these masses of pyrites are very heavy, they rarely find their way into the screened coal for shipment, many hundreds of tons of these "brasses" being annually picked out from the coal at the pit's mouth, and utilised in various manufacturing processes.

The yellow pyrites which form the large masses in the coal, and even the dark varieties when in the crystalline form, remain practically unaltered, even after long exposure to moist air, but the amorphous and finely divided portions, which probably contain lower sulphides mixed with the disulphide, will oxidise and effloresce with considerable rapidity when exposed to moisture and air, forming mixtures of ferrous sulphate and basic sulphates of iron, and it is during this process of oxidation that the heat supposed to bring about the ignition of the coal is generated.

In some of the coals most prone to spontaneous ignition there is only 0·8 per cent. of pyrites, and if we imagined the whole of this to be easily oxidisable, and to be concentrated in one spot instead of being spread throughout the mass, and to be entirely oxidised in a few hours, the rise of temperature would only be a few degrees; whereas, under existing circumstances, it is manifest that practically no determinable increase can be generated by the action.

Under certain conditions the oxidation of masses of pyrites first gives rise to the formation of ferrous sulphate, and sulphur dioxide with liberation of sulphur, and my early experiments led me to believe that inasmuch as sulphur has an igniting point of 250° C., this free sulphur might play an important part in the action, by lowering the point of ignition; later experiments, however, show that this could only take place with large masses of pyrites undergoing oxidation, and that with the amounts present in coal, if the air were present in sufficient quantity to oxidise the pyrites, the small trace of sulphur liberated would be oxidised to sulphur dioxide at temperatures as low as 60° C. This oxidation of sulphur at low temperatures is not a generally known action, but my experiments show that it takes place with considerable rapidity. The only way in which pyrites can assist spontaneous ignition is that when they oxidise they swell, and cause disintegration of the lumps of coal, so exposing fresh surfaces to absorb oxygen and afterwards carry on chemical action.

I have carefully determined the igniting point of various kinds of coal, and find that—

Cannel coal	ignites at	698	deg. F.	= 370	deg. C.
Hartlepool coal	,,	766	,,	= 408	,,
Lignite	,, ,,	842	,,	= 450	,,
Welsh steam coal	,,	870·5	,,	= 477	,,

So that no stretch of imagination could endow the small trace of pyrites scattered through a large mass of coal, and undergoing slow oxidation, with the power of reaching the needful temperature.

When coal is heating, it gives out a distinctive and penetrating odour, which is the same as that noticed when wood is scorched. The gases evolved by the heating coal consist of nitrogen, water-vapour, carbon dioxide,

carbon monoxide, hydrocarbons of the paraffin series, and sulphuretted hydrogen, the presence of the latter gas showing beyond doubt that oxidation of sulphur had nothing to do with the action.

We can now trace the actions which cumulate in ignition. The newly-won coal is brought to the mouth of the pit, and at once commences, by virtue of its surface action, to absorb oxygen from the air; but unless piled in unusually large heaps, and a great deal broken, it does not, as a rule, show signs of heating, as the exposed surface is comparatively small, and the air finding its way freely between the lumps keeps down the temperature. The coal is now screened, and the obtrusively large lumps of brasses picked out; it is then put in the trucks, and enjoys the disintegrating processes of joltings and shuntings innumerable, every jar adding to the per-centage of small coal present, and a corresponding increase in the size of the surface exposed to the air. Arrived at the docks, it has to be transferred from the truck to the ship, which is done by one of the numerous forms of tips, shoots, or spouts employed for the purpose, and it is during this operation that more harm is done than at any other period. The coal first shot into the vessel, by reason of the distance which it has to fall, is broken down into small lumps, and having to bear the impact of the succeeding load falling upon it from a height, rapidly becomes powdered into slack, whilst the succeeding loads falling in on the cone so formed get more or less broken down, so that, by the time the cargo is all taken in, a dense mass of small coal is to be found under the hatchway, and it is invariably at this point that heating takes place, as the large surface exposed fresh to the air by the breaking down of the coal causes rapid absorption of oxygen, and consequent rise of temperature. This sets up chemical combination between the oxygen absorbed by the coal and the hydro-carbons and coal brasses.

On examining the evidence to be obtained as to the conditions under which spontaneous ignition of coal in ships usually takes place, it is found that liability to ignition increases with:—

1. *The increase in mass of coal.*—Thus, in cargoes of under 500 tons the cases reported amount to a little under ½ per cent. for shipments out of Europe; from 500 to 1,000 tons, to over 1 per cent.; from 1,000 to 1,500 tons, to 3·5 per cent.; 1,500 to 2,000 tons, to 4·5 per cent.; and over 2,000 tons to no less than 9 per cent. The evidence demonstrating this very remarkable result is to be found in the Report of the Royal Commission for 1875, p. 8, and clearly shows the influence of mass upon this action, which acts in two ways:—(*a*) The larger the mass, the more non-conducting material will there be between the spot at which heating is taking place and the cooling influence of the outer air. (*b*) The larger the mass the greater will be the breaking-down action of the impact of coal coming down the shoot upon the portions first loaded into the ship, and the larger, therefore, the fresh surface exposed to the action of the air.

2. *The ports to which shipments are made.*—26,631 shipments to European ports, in 1873, only resulting in ten casualties, whilst 4,485 shipments to Asia, Africa, and America gave no less than sixty. This startling result is partly due to the length of time the cargo is in the vessel, the absorption and oxidation being a comparatively long action; but a far more active cause is the increase in the action brought about by the increase of temperature in the tropics, which converts a slow action into a rapid one, and if statistics had been taken, most of the ships would have been found to have developed active combustion somewhere about the neighbourhood of the Cape, the action developed in the tropics having raised the temperature to the igniting point of the coal by that time.

3. *The kind of coal,* some coals being specially liable to spontaneous heating and ignition. This is a point on which great diversity of opinion exists, but I think it will be pretty generally admitted that cases of heating and ignition are more frequent in coals from East Coast ports than in shipments of the South Wales coals.

The idea that the per-centage of pyrites present is any indication of the liability to spontaneous combustion, must be entirely discarded, as experiment shows that many coals poor in pyrites frequently ignite, whilst others rich in them are perfectly safe.

A much surer guide is to be found in the quantity of moisture present in an air-dried sample of coal, which is a sure index to the absorptive power. The higher the amount of moisture held by the coal, after exposure for some time to dry air, the greater will be its power of absorption for oxygen, and the greater therefore its liability to spontaneous heating and ignition.

This is beautifully shown by the following Table, in which the per-centage of pyrites and

moisture present in some coals are contrasted with their liability to self-ignition:—

Liability to Spontaneous Ignition.	Pyrites per cent.	Moisture per cent.
Very slight	1·13	2·54
	1·01 to 3·04	2·75
	1·51	3·90
Medium	1·20	4·50
	1·08	4·55
	1·15	4·75
Great	1·12	4·85
	0·83	5·30
	0·84	5·52
	1·00	9·01

The per-centage of moisture shown in this Table is not due to external wetting, but is moisture absorbed from the air and held by the coal, so that the amount of it present is an indication of the power of absorption possessed by the coal, and which will give it the power of taking up oxygen as well as water vapour.

4. *The size of the coal*, small coal being much more liable to spontaneous ignition than large. This, as has been pointed out, being entirely due to the increase in active absorbent surface exposed to the air, a fact which is verified by the experience of large consumers of coal on land; gas managers recognising the fact that coal which has been stamped down or shaken down during storage being more liable to heat than if it has been more tenderly handled, the extra breakage causing the extra risk.

5. *Shipping or storing coals while wet.*—The effect of moisture upon coal is very remarkable. At first external wetting retards the absorption of oxygen by the coal, but the presence of moisture afterwards increases the action of the already absorbed oxygen upon the hydrocarbons of the coal, and so causes a serious increase in the heating. Of late years the researches of Cowper, Baker, Dixon and others have shown so fully the important part which moisture plays in chemical combination, that it is now fully recognised as a factor of importance in actions of this kind. During last autumn, a very marked case of the influence of moisture in the action taking place came under my notice:—A ship took in a cargo of coal at a South Welsh port, the weather being fine and dry whilst she was loading at the main hatch, and wet whilst taking in the coal at the after hatch, with the result that the temperature after the first few days was uniformly about 10° higher in the coal that had been loaded wet than in the dry portion of the cargo, spontaneous ignition being the ultimate result.

6. *Ventilation of the mass of coal.*—The so-called ventilation, which has from time to time been introduced into coal ships, is undoubtedly one of the most prolific causes of spontaneous ignition. For ventilation to do any good, cool air would have to sweep continuously and freely through every part of the cargo, a condition impossible to attain, whilst anything short of that only increases the danger, the ordinary methods of ventilation supplying just about the right amount of air to create the maximum amount of heating. The reason of this is clear. A steam coal absorbs about twice its own volume of oxygen, and takes about ten days to do it under favourable conditions, and it is this oxygen which, in the next phase of the action, enters into chemical combination, and causes the serious heating. A ton of steam coal occupies 42 to 43 cubic feet, and if properly loaded contains between the lumps, as nearly as possible, 12 cubic feet of air space, that is to say, of the 42 cubic feet 12 cubic feet is air, and 30 cubic feet is coal. Thirty cubic feet of coal, with its fresh absorbing surfaces laid bare by the crushing incidental to loading, will, in the first ten days after being taken on board, absorb 60 cubic feet of oxygen, if it can get it. Now, air contains only, roughly, one-fifth of its volume of oxygen, so that 60 cubic feet represent 300 cubic feet of air, or twenty-five times as much as is present. It is therefore evident that if air could be excluded, there would be only one twenty-fifth the quantity of oxygen present that is needed for complete action, and any heating would, in consequence, be very slight; whilst to produce the greatest heating it would be necessary to change the entire air in the cargo twenty-five times in the first ten days, and this is just about what the old method of taking a box shaft along the keelson with venetian lattice upshafts from it would give.

The most forcible illustration of the evil of such ventilation is to be found in the case of the four colliers, *Euxine*, *Oliver Cromwell*, *Calcutta*, and *Corah*, which were loaded at Newcastle under the same tips, at the same time, with the same coal, from the same seam. The first three were bound for Aden, and were all ventilated. The *Corah* was bound for Bombay, and was not ventilated. The three

thoroughly ventilated ships were totally lost from spontaneous ignition of their cargo, whilst the *Corah* reached Bombay in perfect safety.

7. *Rise in Temperature.*—It has been fully pointed out that anything which tends to increase of initial temperature increases the rapidity of chemical action, and in most cases of spontaneous combustion in coals stored in this country, the cause can be traced to a steam pipe or boiler-flue in contact with the mass of coal, or even fixed to a wall against which, on the other side, the coal is heaped. Sometimes the coal store is close to the benches of retorts in a gas works, or even against the wall of the benches, and in such cases, with certain classes of coals, ignition would be almost certain to take place. In a paper read at the last meeting of the Gas Institute, it was proposed to lead the flues from the benches under the coal store, in order to dry the coal, a device which would infallibly lead to spontaneous ignition.

On colliers there are many causes for increased temperature, amongst them being the introduction of triple expansion engines and high-pressure boilers. Steam at 80 lbs. boiler pressure has a temperature of 324° F. (162° C.), and a common stoke-hold temperature, with boilers worked at this pressure, is 100° to 130° F. (or 38° to 54° C.) Steam at a boiler pressure of 155 lbs. has a temperature of 368° F., or 186° C., and gives a corresponding increase of temperature in the stoke-hold and other adjacent portions of the vessel, the temperature in the stoke-hold under these conditions being from 110° F. (43·5° C.) to 140° F. (60° C.), an increase of about 10° F.

Then, again, donkey boilers will often be found recessed into bunker bulkheads, and steam pipes led alongside the bulkheads, with the cargo close up against them on the other side. The effect of temperature due to climatic influences has already been dealt with under the influence on ignition of ports to which shipments are made.

Having now discussed the chemical and physical conditions which lead to the phenomenon known as "spontaneous ignition," we can formulate precautions which will tend to prevent such disasters.

1. *The choice of coal for storage or shipment.*—The coal should be as large as possible, free from dust, and with as little "smalls" as can be helped. It is better as free from pyrites as possible, and it should contain, when air-dried, not more than 3 per cent. of moisture.

2. *Precautions to be taken in storing or loading.*—The coal store should be well roofed in, and have an iron floor bedded in cement, all supports passing through and in contact with the coal should be of iron or brick; if hollow iron supports are used, they should be cast solid with cement. The coal must never be loaded or stored during wet weather, and the depth of coal in the store should not exceed eight feet, and should only be six where possible. Under no condition must a steam or exhaust pipe or flue be allowed in or near any wall of the store, nor must the store be within twenty feet of any boiler, furnace, or bench of retorts. No coal should be stored or shipped to distant ports until at least a month has elapsed since it was brought to the surface. Every care should be taken during loading or storing to prevent breaking or crushing of the coal, and on no account must a large accumulation of small coal be allowed. These precautions, if properly carried out, would amply suffice to entirely do away with spontaneous ignition in stored coal on land, and we have now to consider a far more important phase of the question.

3. *Precautions to be taken on board coal-laden ships.*—This phase of the question is undoubtedly the most important, and in order to ensure any successful treatment of the coal cargo at sea, to prevent undue heating and ignition, the means adopted must be as nearly automatic in their working as possible, as it is useless to expect the master or any officer on board a collier during rough weather, &c., to comply with any instructions, such as daily taking the temperatures in various parts of the cargo, and so on.

The iron bulkheads dividing the coal storage from the other parts of the vessel should be made double, and spaced six inches to a foot apart, with openings (which could be closed water-tight) every few feet, to allow of the interior being from time to time coated with protective compositions. Through this double casing sea-water would be allowed to circulate, and would not only effectually prevent any penetration of heat from the stoke-hold, boilers, or engine-room to the coal, but also do away with any chance of leakage of gases from the coal cargo into other portions of the vessel, and so would minimise the danger of explosions.

A similar double partition should run down the centre of that portion of the vessel in which the coal was stored, and it would be sufficient

if this were packed with silicate wool; this partition would serve to prevent any heating which might take place in one part of the cargo being communicated to the other half, whilst it would also perform the important function of helping to prevent shifting of the cargo during heavy rolling.

When the coal has all been taken in, it should be battened down, and the hatches should not be again opened until the vessel reaches her destination, the only ventilation allowable being a 2-inch pipe just inserted into the crown of each coal compartment, and led twelve feet up the nearest mast, the top being left open. This would be quite sufficient to allow free egress to any gases evolved by the coal, but would not allow undue excess of air.

Into the body of the coal cargo itself would be screwed, at regular intervals of about 10 feet, iron pipes, closed at the bottom, and containing alarm thermostats, so arranged that when a rise of temperature causes expansion of the mercury in rising in the tube, it makes a contact; and the wires from these tubes are in connection with an electric bell, index-board, and battery in the captain's room; so that the moment the temperature is reached to which the thermometers have been set the bell rings, and will continue to ring, until the temperature again sinks, the spot in which heating is taking place being indicated by the index-board.

In the evidence given before the Commissioners in 1875, Mr. J. Glover strongly advocated the use of carbon dioxide, or carbonic acid gas, as it is more usually termed, for extinguishing ignition when it had broken out in a coal cargo, and for stopping heating when it had reached a dangerous pitch. His proposal was to generate the gas by the action of hydrochloric acid upon chalk, and to lead it by gas pipes to the compartment affected; and this gas, being heavier than air, and a non-supporter of combustion, was to displace the air and its contained oxygen, and so to prevent further action by surrounding the coal with an atmosphere which could not carry on combustion. The idea was a good one, but there were many difficulties in the way of carrying it out, one being that, for every 1,000 tons of coal carried, 80 cwt. of hydrochloric acid would have had to be shipped; also the gas could not have been driven down into the hold if any serious heating had taken place, as an up-current would have been formed, and would have carried it away; whilst in the state of gas, it fails to give any great cooling effect, and so would have exercised but little influence upon the mass of red-hot fuel. These objections weighed so strongly with the Commissioners that, in their final report, we find the following sentences:—

"Several methods for generating carbonic acid gas, and applying it to the ignited portion of a coal cargo, have been proposed for our consideration. We consider, however, that although this gas might be useful for excluding atmospheric air (which is essential to support combustion), yet it will not, as water does, exert any very sensible cooling effect, *which is a point of vital importance in the case of a mass of ignited coal.* We are of opinion that water and steam are the only agents practically available for the purpose of extinguishing fire in coal cargoes."

Applied in the way which was suggested, there is no doubt but that the carbonic acid gas would have been practically useless; but there is another way in which it could be used, which would make it a most powerful cooling agent, an instantaneous quencher of fire, and would prevent any further tendency to heat on the part of the coal treated with it.

If carbonic acid gas is compressed under a pressure of 36 atmospheres at a temperature of 32° F. (0° C.), it is condensed to the liquid state, and can be obtained in steel vessels closed with screw valves. On opening the valve some of the liquid is ejected into the air, and, in coming into the ordinary atmospheric pressure, is in a moment converted into a large volume of gas. Conversion from the liquid to the gaseous state means the absorption of a large amount of heat; and so great is this, that everything near the stream of new-born gas is cooled down, and some of the escaping liquid is frozen to a solid, having a temperature of - 78 C., or - 108·4 F.

This liquid carbonic acid gas is now extensively manufactured, and is used abroad to a large extent for aërating waters, driving torpedoes, and for freezing machines; and I should suggest its use in the following way for the checking of ignition in the coal cargo:—

The nozzle attached to the screw-valve on the bottle of condensed gas should have a short metal nose-piece screwed on to it, the tube in which should be cast in solid, with an alloy of tin, lead, bismuth and cadmium, which can be so made as to melt at exactly 200° F. (93° C.). The valve should then be opened, and the steel bottle buried in the coal during the process of loading. The temperature at which the fusible metal plug will melt is well above the temperature which could be reached by any legitimate cause, and would mean that active heating was

going on in the coal; and under these conditions the pressure in the steel cylinder would have reached something like 1,700 lbs., and the moment the plug melted the whole contents of the bottle would be blown out of it into the surrounding coal, producing a large zone of intense cold, and cooling the surrounding mass to a comparatively low temperature. The action, moreover, would not stop here, as the cold, heavy gas would remain for some time in contact with the coal, diffusion taking place but slowly through the small exit pipe.

When the coal has absorbed as much oxygen as it can, it still retains the power of absorbing a considerable volume of carbonic acid gas; and when coal has heated, and then been rapidly quenched, the amount of gas so absorbed is very large indeed, and the inert gas so taken up remains in the pores of the coal, and prevents any further tendency of heating; indeed, a coal which has once heated, if only to a slight degree, and has then cooled down, is perfectly harmless, and will not heat a second time. It is not by any means necessary to replace the whole of the air in the interstices of the coal with the gas, as a long series of experiments show that 60 per cent. of carbonic acid gas prevents the ignition of the most pyrophoric substances.

One hundred cubic feet of gas can be condensed in the liquid state in a steel cylinder one foot long and three inches diameter, and it has been shown that a ton of coal contains air spaces equal to about 12 cubic feet; therefore, one of these cylinders would have to be put in for every eight tons of coal, as, although the gas formed at the first moment would only occupy a small space, on account of its low temperature, it would rapidly expand in contact with the hot coal. These cylinders should be distributed evenly throughout the cargo, and near the alarm thermometers, which should be set to ring a degree or two below the point at which the fusible plug would melt.

The bell ringing in the captain's room would warn him that heating was taking place, and the bell would continue to ring until the cylinder had discharged its contents, and had cooled the cargo down to a safe degree, so that the whole arrangement would be purely automatic, and yet the officers would know if everything was safe.

This liquid is now being made at a comparatively cheap rate, and, with any demand for it, machinery could be put up at the principal coaling ports, to charge empty cylinders at a very low rate, so that the initial cost of the steel cylinders once got over, the expenses would not be worth considering, more especially as one, or two at most, of the cylinders in use, would be likely to go off.

If the precautions advocated were taken, on danger could arise until the arrival of the ship at her destination, and the commonest precautions would then suffice. On removing the hatches no naked light must be allowed near them, and no one must be allowed to descend into the hold until all the gases have had time to diffuse out into the air. If the cylinders have gone off, there will be but little fear of explosion, as a high per-centage of the carbonic acid gas lowers the explosive power which the mixture of marsh gas (given off from some coal) and air possess; but the carbonic acid gas would overcome and suffocate a man descending into an atmosphere containing any considerable per-centage of it. When a safety lamp, lowered into the hold, continues to burn as brightly as it did in the open air, then it is perfectly safe to descend.

When once coal in a cargo has fired, pumping in water is of practically no use, as the fire is, as a rule, near the bottom of the mass of coal, and the flow of the water is so impeded by the caking of the heated mass above the fire, that in percolating through the interstices of the heated coal, it is converted into steam before it can reach the seat of combustion. The most effective way to apply water would be to have three-inch pipes laid along the floor of the coal compartments, about six feet apart, these tubes having a quarter-inch hole bored in the upper side every foot or so, and each pair of pipes coming through the bulk-head, and connecting on to two six-inch pipes passing through the side of the vessel, the sea water being prevented from entering by means of screw valves. As soon as the alarm thermometer gave notice that heating had reached a dangerous point, these valves could be opened and the lower portion of the cargo drenched with salt water. This, evaporating rapidly, would give large volumes of water vapour, which, passing up through the heated coal, would lower its temperature, but would not be nearly as effective as the method before advocated. It might, however, be used in conjunction with that method, and would, in many cases, save the carbonic acid gas.

In the case of coal bunkers in modern steamers and warships, the conditions under which the coal is placed are so totally different from those existing in a collier, that no comparison can be drawn between them.

In the coal bunker, the question of mass,

which plays so important a part in a hold laden with coal, is almost entirely eliminated, as 50 to 400 tons would be about the capacity of any ordinary bunker, and it has been before shown that the cases of spontaneous ignition in masses of coal less than 500 tons does not amount to more than quarter per cent., and the question of initial temperature becomes the most important factor.

A few years ago, such an occurrence as a coal bunker on fire was rare, whilst at the present time hardly a week passes without some more or less serious cases occurring on the fast liners, and it is evident that there must exist some well-defined cause for this enormous increase in cases of spontaneous ignition. On collecting evidence on this point, the first thing that strikes one is that bunker fires are almost entirely confined to vessels in which the bunker bulkheads are only separated from the funnel by a narrow air-space, or in close proximity to the boilers themselves, but where the bunkers are stepped back from the funnel casing and boilers, spontaneous ignition is a great rarity.

Taking the case of a fast liner, it is found that the temperature in a coal bunker varies very considerably, according to its proximity to the air channel round the funnel casing. Close to the outside of the bulkhead the temperature is often as high as 200° F. (93° C.) whilst inside 120° would be a fair estimate, and from the centre of the bunker to the side of the vessel it is seldom above 75°F (24° C.); the temperature, however, being higher near the iron decks, which, being in contact with the heated bulkhead, conduct the heat through the coal, and raise the temperature often up to 100° F.

It has been pointed out that if coal be kept at a high temperature, even though it be far below its igniting point, ignition is only a question of time; and if the bunker coal next the bulkhead be kept at 120° F., any coal with a tendency to absorb oxygen will run a great chance of igniting within a few days. It is manifest that if this is the real cause of ignition, the seat of the fire ought to be found close to the heated bulkhead, but this is very often not the case, the mass of fire being found near the centre of the bunker, and sometimes even towards the sides of the vessel; but careful examination soon reveals the cause of this, as a line of charred coal is mostly to be found running from the heated bulkhead to the seat of active combustion, showing that the fire started by the high initial temperature has not had sufficient air near the bulkhead to do more than smoulder, but that as soon as it came in contact with a current of air passing up through the coal from the hatches in the decks, the smouldering mass began to burn fiercely.

In order to prevent spontaneous ignition of the coal under these circumstances, all that is necessary is to reduce the temperature of the bulkhead in contact with the coal, as if this is kept at a temperature not exceeding 82° to 90° F., there is little or no fear of the oxidation of the hydrocarbons of the coal proceeding with such rapidity as to cause ignition in such a quantity of coal as can be carried in the bunkers; the iron decks, by subdividing the mass, also helping to reduce any risk.

In order to reduce the temperature to the required extent, it would be necessary to make the bulkheads close to any heating surface, such as the funnel casing, double.

Through this double casing sea-water would be allowed to circulate very slowly, and would effectually prevent any undue rise of temperature; whilst, to make the arrangements complete, a thermostat should be fixed on the inner plate of each bulkhead, which, if the temperature rose to 100° F. (38° C.), would ring a bell in the captain's room, when the rate of flow of water could be increased until the required fall in temperature took place.

Should this arrangement prove impossible from any structural cause, then a rapid current of air forced through the bunkers by means of a fan, or even an up-current formed by a good air-pump ventilator in the crown of the bunker, would go far to keep the temperature within safe limits.

In a coal cargo, perfect ventilation is impossible on account of the mass of coal present, and, therefore, the hold should be battened down, and everything done to prevent imperfect ventilation, gas-tight bulkheads being a necessity for this purpose.

In coal bunkers, on the other hand, on account of free access being obtained to both top and bottom of the coal, and also the small mass present, perfect ventilation is possible, and should be attempted, whilst the water bulkheads will do away with any undue rise of temperature.

Chemists have been repeatedly asked if analysis gives no indications by which a coal, liable to spontaneous heating, can be distinguished from another which is perfectly safe for storage or shipment in bulk; but, up to the present time, the action has been so little understood, that no such differentiation was

possible, but with a clear conception of the causes which lead to heating, it should be quite possible to do so.

As I have shown, all coals, when heated to a temperature a little above that of boiling water, have their power of absorbing oxygen so increased that they will, in a few hours, absorb sufficient to give a perceptible increase in weight, and the greater their absorption power the greater will the increase be; and as it is upon this that the liability to heat depends, the amount of increase in weight would give a sure indication of the liability to spontaneous ignition. We have at present, however, no data to show what is a safe amount of absorption and with what amount danger commences, and the owners of collieries yielding coal liable to heating are so anxious to prevent the fact leaking out, that there will be considerable difficulty in obtaining authentic samples to make the determination with.

My own experience, however, leads me to think that if an air-dry coal does not contain more than 3 per cent. of moisture, and when powdered and heated to about 250° Fahr. in an oven for three hours does not increase more than about 2 per cent. in weight, it may be looked upon as a safe coal to store in bulk.

I am perfectly aware that the precautions I have suggested will never, unless pressure is brought to bear upon them, be adopted by the owners of colliers, on account of the slight extra expense and trouble they would involve; but if Lloyds could be prevailed upon to lower the rate of insurance upon coal cargoes treated in this way, and substantially increase the rate upon cargoes in which these precautions had not been adopted, a class of disaster as appalling in nature as it is destructive in result would soon be entirely done away with.

DISCUSSION.

Sir James Douglass, F.R.S., desired to thank Professor Lewes for what he had done in the way of providing a way of safety for those who had to convey coal to distant parts. The method proposed certainly seemed a little troublesome to shipowners, but it was not very expensive; and if it ensured safety to coal ships, as it seemed to do, it ought to be adopted. He hoped Lloyds would see their way to encourage owners to adopt these necessary precautions. He should certainly urge the adoption of the necessary precautions with regard to the storing of coal in bunkers in any case he had to deal with.

Mr. Francis Cobb thought if the attention of Lloyds were drawn to this paper, underwriters would very speedily fall in with the suggestion that properly protected ships should be insured at lower premiums than those which were not; and he should be glad if means were taken to distribute the paper amongst those interested. Up to the present it appeared that most people had been acting under a grave misapprehension. Considerable expense had been incurred in ventilating coal ships, especially those going to the west coast of America and the East Indies, and now it appeared that this was a step in the wrong direction. He knew of one case where an old American captain refused to have any ventilation, as he was loading his vessel for the west coast of America, and a fine iron ship alongside of him was ventilated at great expense; but in the end the old wooden ship delivered her cargo cool and in good condition, while the fine English ship was burned. The one captain closed his hatches as quickly as possible, and never opened them again till he got to his destination, whilst the other put up wind-sails to blow air right through the cargo, which, at that time, they had been taught was the proper thing to do. If anything could be devised by which the liquid carbonic acid could be used without having a bottle for every eight tons of coal, which seemed to him impracticable, it would no doubt be very useful. If it could be carried in larger bulk, and distributed where it was required, there would be no difficulty in fitting ships to carry it.

Mr. W. E. Stanley Thomson said he had been favoured by Professor Lewes with an early copy of the paper, and had had communications from him before, and he had therefore taken the trouble to make himself acquainted with the results of the inquiries which had been held since the report of the Commission in 1876. Professor Lewes's theory was, to some extent, contrary to the opinion of some very able men who sat on that Commission, notably Sir Frederick Abel and Dr. Percy, which had been generally followed by courts of inquiry since. In one case, an inspector or manager of mines expressed the opinion that, unless there were pyrites in the coal, it would not fire; and the general opinion of the Courts, since 1876, had been that it was generally pyrites which caused spontaneous combustion. Professor Lewes challenged this entirely, and had given some statistics bearing out his view, but his information went no further than 1883; if he had taken the last three years for which the Board of Trade had made returns, he would have have found that they gave an average of something like 25 coal-laden ships per annum which were either known to have been abandoned or were missing, and 200 lives lost. This was a very serious matter, and, if Mr. Lewes were right, the existing precautions were altogether insufficient and illusory, though they were founded on the report of the Royal Commission. That Commission called special attention to a paper by Sir Frederick Abel and Dr. Percy, explaining scientifically the cause of spontaneous com-

bustion, in which a great deal of space was devoted to the part taken by pyrites, though later on they also explained that coal itself was liable to oxidation, and, after explaining the process, they expressly said that this oxidation of the coal was one of the causes, if not the chief cause, of spontaneous combustion. It was strange therefore that, during all these years, not one word had been said, in the course of the many inquiries which had been held, and in which the courts have often been in doubt, to suggest that this was the probable explanation of the ignition of the cargo. On the contrary, attention seemed to have been confined solely to discovering whether the coal in question had pyrites in it, and whether it had been sufficiently screened. Since 1876 there had been altogether 34 inquiries in which the Courts found that the cargoes had fired from spontaneous combustion; but, to make a fair comparison, he had selected those in which the ships were bound to South America, or round Cape Horn. Of these there were 23, of which in nine cases only did the Courts find that pyrites was positively present in any quantity; in 14 it was either absent or present in such infinitesimal quantity that they were unable to assign any cause for the fire. Then, too, the average time from leaving port in which the vessels fired was, where pyrites were present, 2 months, 23 days, when absent, 2 months and 20 days, and this was very important evidence, as showing how little pyrites really had to do with firing these cargoes. He had tabulated these cases, classifying the information obtained as to the class of coal, whether wet or dry, the time the vessel sailed, ventilation, and so on, with a view to getting some explanation of the reason why some cargoes fired in, say two months, while other ships—sailing, apparently, under similar conditions, as regards the coal on board—had taken three months, or even longer, to fire; and it would be found that the conditions of heat and ventilation were important, and had very much to do with this. Vessels which went through the tropics, during the sun's northward course, would travel through the tropics at a time when they would have the longest period of extreme heat on the voyage; but if the sun were on its southern course, the vessel would have the extreme heat for a shorter time. With regard to ventilation, the Courts seem to have had some difficulty in deciding whether iron masts, perforated below the decks, were injurious or not. Through ventilation was now always condemned, especially when lattices were used; but platforms and trunkways had also been deemed dangerous. The most important point perhaps was the management of the hatches, and on that he had collected the following information:—Particulars are not always given in the reports as to the keeping on or taking off the hatches; but where such information is given, there is abundant evidence to show that taking them off to cool the cargo, when it has given evidence of heating, or to dig down and get at the seat of the fire, or to see how the fire is progressing, accelerates combustion in a most alarming way. For instance, the temperature of the *Nagpore's* hold was found to be getting very high—it showed 95° by the thermometer—and next day it was 110°. At this time, the fore and main hatches were off, and by next morning the temperature rose to 120°. Still keeping off the hatches, the thermometer next day registered 130°, and then fire broke out. In the case of the *Mountaineer*, upon smoke appearing, the hatches were taken off, but after trimming the cargo, they were replaced and battened down for the night. Next day they were taken off, to see how matters were progressing, but the smoke was so intense, that the master closed up the hold at once; and after sundry minor explosions next day, the ship finally blew up. This coal had little or no pyrites in it, and had not been much broken, nor was it wet when put on board. Here is another case, in which the coal was clean and dry, but a good deal broken, the *Gad's Hill*. When 96 days' out, smoke was noticed coming from the forehold. Digging down to the seat of the fire, and douching the coals vigorously, they, in four days, believed that they had effectually flooded out the fire. Four days afterwards, however, smoke appeared from the after hold. Attempts to get at the seat of the fire proved a failure, for a foot below the surface the diggers were met by so much steam and smoke, that they were obliged to desist. The hatches were then put on, in hopes of smothering the fire, but this failing, they were again thrown open, to allow the heavy seas, which were breaking over the ship, to fall into the holds; but the fire increased so rapidly, that, on the following day, the crew had to abandon the ship. In this case, the usually supposed causes of spontaneous combustion were not present; and the combustion must have been developing a long time before the first appearance of smoke. How far, previous to the smoke, the opening of the hatches may have contributed to the combustion, we cannot say; but the consequences of keeping off the hatches while digging, and uncovering them, to allow the seas to wash in, are conspicuous in the rapidity with which the fire spread. Here, again is an instance of combustion which probably had been in a state of quiesence for want of air, and was brought into vigorous operation through opening the hatches. The *Yuca* had a cargo which the Court found had pyrites in it, but it had been put on board dry, and not much broken. The vessel was 98 days out on her voyage, and it was necessary to trim the cargo, which had shifted. On opening the hold they found "no signs of heat or gas from the coal;" but, next day, two of the crew were nearly suffocated by gas, and, on examination, the hold was found to be full of it; but still there were no signs of fire. By way of precaution, the hatches were battened down; but, having to get out the cable, they were again opened about twelve hours afterwards, and, as the smoke was very great, they were soon put on, and battened down again. In the course of the next 24

hours, the ship fortunately came in sight of land; but, meanwhile, her main hatch had been blown off, and the flames were coming out of her on both sides, fore and aft, whereupon the crew abandoned her. This is not the only case in which the crew have been deluded into the supposition that all was going well by finding only normal temperature at the surface of the cargo. From similar experience in the *Slieve More*, and other cases, one might assume that combustion had been in active operation, but had lain dormant for some time for want of air, so that there would not be that intense heat at the bottom of the hold which would affect the temperature on the surface of the coal. Anyway, in the *Yuca* case, the course of events positively shows how active is the assistance which the open hatches contribute in developing spontaneous combustion, when there is a tendency to it in the coal at the bottom of a ship's hold. Next comes a case where the hatches had practically always been off. The *Carr Rock* had a cargo in which there was little or no pyrites; it was not more than usually broken, and was put on board dry. At starting, the thermometer indicated 75° Fahr. in her hold; a month afterwards it was 98°, and in another month 120°, whereupon they dug down into the coal; and as at a depth of four feet it was palpable that there was fire all over the hold, they stopped work and clapped on the hatches. Next day the hatches were taken off to see how matters were progressing, but finding the fire was burning furiously, they were soon replaced. Water was poured into the hold; in a few hours explosions occurred, and soon afterwards the crew were obliged to abandon the ship. Here, too, we have none of the usually supposed causes of spontaneous combustion — no pyrites, no wet, no coal in a very broken condition—but we have the fact that the hatches were constantly open, and the coal would probably have been put on board fresh from the pit in a very absorptive condition. We have, therefore, an instance which actually bears out Professor Lewes's contention. From these illustrations, then, may we not assume, as a general principle, that the coal goes through a very simple process? It comes into the ship green, and that part of it which has been most broken, and lies at the bottom of the hold, immediately beneath the hatches, slowly heats. The air which surrounds it becomes warm, and ascends, while the cool air from above rushes in to take its place, and so supplies the oxygen required to assist in the process of combustion; meanwhile, perhaps, the hatches are off, but wet or rough weather sets in, and the hatches are battened down. The hold is then warmer, and combustion is accelerated so long as there is air within reach; and when that air is exhausted, combustion is at a standstill, and would actually remain quiescent so long as no air can get to it; but, with the return of fine weather, the hatches are removed, the hot air then rushes up from below, a new supply of oxygen is drawn down to the now almost burning coal, and, in a few hours, the cargo is alight fore and aft. If this is a correct theory, Professor Lewes is perfectly right as regards keeping the hatches always closed. But now, as regards the sufficiency of the present precautions—assuming that oxidation of the coal and not pyrites is the cause of spontaneous combustion—the existing regulations are incomplete. It is simply required that the coal should not be broken more than could be helped, that pyretic coal should not be put on board wet, and that ventilation through the cargo should be stopped. But what about green coal which is freshly won from the pit, and in its most absorptive condition? What about the facilities on board, through the hatches, for its getting air to sustain and accelerate combustion. It seemed to him that the alarm thermometers suggested by Professor Lewes might be dispensed with, even with advantage, because what was wanted was not the exact spot in which the coal was on fire, but the fact of fire existing anywhere, and that would probably be given by the exit pipe for the gas surface. That gas was inodorous, but when the cargo was burning there must be smoke, which could be seen, and then the only thing was to make for the nearest port. The carbonic acid seemed promising, but it had been tried and failed under some conditions. In one of the colonies, some years ago, a ship was specially fitted up for the special purpose of applying it when vessels on fire came into port, but on one occasion it was poured into the hold of a vessel for several hours without success. Last year a number of people were invited to see some experiments at Liverpool, and a large bonfire in a ship's hold was speedily extinguished, but that could hardly be considered an analogous case. Still, he thought Mr. Lewes had made out a good case for the use of carbonic acid, and certainly he had contributed much information by his most interesting and valuable paper.

Mr. I. G. LORRAIN said he did a good deal of work on this subject some seven or eight years ago, and it was then urged upon him that an alarm was not what was wanted. A captain told him that he did not want to know that the cargo was on fire, he wanted to know what condition the hold was in before it got to that, so that he might take precautions. Charpontier's arrangement, which was somewhat similar to that now suggested, was met with the same objection. The carbonic anhydride arrangement was not new to the Society, as he had made a similar suggestion in 1885, laying stress on its cooling action, as well as on its being a non-supporter of combustion, and in November, 1885, Prof. Silvanus Thompson showed a diagram of the apparatus. With regard to putting a fuse in the mouth of the bottle, it was not always possible to have the bottle in the place where the fire broke out, but he had found a good arrangement was to add some insulating material near the mouth, and mount the fuse in such a way that it acted like a fuse in an electric circuit; then by putting a thermostat in

places where the fire was likely to occur, and having a source of energy sufficient to supply an excess of current that might be relied upon to melt the fuse.

Capt. ANDREW CUNNINGHAM thought when Professor Lewes' views were subjected to a little wholesome criticism by practical men, they might lead to useful results. He had had considerable experience with coal cargoes; and, having come to grief with the first one, he learned so many useful lessons, that he never had another accident. His conclusions were somewhat at variance with those now put forward. He could not go into the chemical part of the question, but, it seemed to him, that moisture was the principal element in determining the combustibility of a cargo. It seemed a truism to talk of the oxidation of pyrites being the cause of ignition. It was like saying that a man died from want of breath. His experience, on his first voyage, was much what Mr. Thomson had indicated, except that he omitted what every master was told by the shipper, that a cargo of that particular coal had never been known to take fire. He sailed from Dundee for San Francisco, and, wishing to be as careful as possible, he kept the hatches up, and had a trunk along the keelson, and an upright shaft too. After a time, when the weather got rougher, he put the hatches on, and was not in a great hurry to get them off; but, 86 days' out, he was told by the second officer that smoke was coming out of the fore hatch. He then took all the hatches off, and began pouring water down, and, after a time, the amoke disappeared. They continued pouring in water during the night, but the following day it became serious, and they began throwing coal overboard, until they got to the lower deck beams; then the coal began to get red-hot under the men's feet, and they had to stop. Then he turned the hose from a donkey-pump into the main hatch, filled the cavity with water, and put on the hatches and battened them down. About midnight there was an explosion, and the next morning he was told that the men were coming aft to ask him to abandon the ship. However, he took off the main-hatch, and found it as cool as an ice-house, the beams and timbers being all covered with coal tar, and he never had any more trouble for the rest of the voyage. The lesson he learned was, as soon as possible after leaving home to insert iron rods down the main and after hatches, by means of which he could tell by the hand how the temperature was getting on. Perpendicular shafts were quite unreliable as a test of temperature; he had seen a thermometer in one of them give a lower temperature than there was on deck, and at the same time he could hardly bear his hand on an iron rod not more than five feet off. He always dug out the main hatch down to the lower deck beams, so as to be all ready for putting water in. He thought the iron rods which he used as indicators might also be of use in conducting away the heat, and allowing it to escape into the air. He had never had any trouble since, though he had been more than once becalmed in the tropics. It was most dangerous to batten down the hatches, considering the large quantity of gas evolved. Professor Lewes had little notion of what shipowners were, or he would not recommend double bulkheads. The great point, in his opinion, was surface ventilation; the hatches should always be kept open, and a ship properly loaded would never take in any water which would injure her. The thermostat might be a nice thing for a laboratory, but would not do for a sailor. He gathered that the *Carr Rock* was filled block up between the beams, and there could not be surface ventilation unless there were several feet to spare between the decks.

Sir JAMES DOUGLASS could not understand how Captain Cunningham could place so much faith in surface ventilation, seeing it was not at all uncommon in the North of England to see a heap of coal on fire in the open air.

The CHAIRMAN said Professor Lewes, in the paper he read at Cardiff, and again in the one he had just read, had taken the first step necessary in devising preventive measures, viz., to point out the causes of the evil to be guarded against. He had disproved the pyrites theory, because, though he did not say it had no effect whatever, he had shown that with coal absolutely free from pyrites, there was sufficient heat generated by the absorption of oxygen to cause spontaneous ignition, unless means were taken to prevent it under the conditions stated. One striking point was the increase of danger as the size of the cargo increased, especially in tropical climates. Two things recommended, he thought, would be found practically impossible. Double bulkheads would be very costly to make and keep watertight, and would take up a great deal of space. It was admitted that no one would use them except under the pressure of legislation; but they could not legislate for foreign countries; and, if too heavy burdens were imposed on English shipping, other people, not subject to the same restrictions, would come and take our trade away. Another suggestion was that coal should not be shipped until it had been a month out of the pit, but that might involve so much expense in removing from one place to another, or from one railway waggon to another, that it would be prohibitive. Coal owners' profits were measured by pence rather than by shillings per ton, and would not bear much diminution in this way. The proposal for the introduction of thermostats into the bulk to show what was going on, reminded him of a difficulty which the late Sir William Siemens experienced from the deterioration of certain cables stored on board a vessel, when he discovered by means of electrical thermometers that there was a spontaneous rise of temperature in them. As a result of those experiments jets of water were flowed over the cables, and, finally, it became the practice to coil the cable in a tank which could be filled with water. He did not see why the use of liquid carbonic acid should not

be available. Many voyages would take place without any liberation of the carbonic acid, and even where it was liberated the cost would not be prohibitive. It was clear that if the temperature could be kept down ignition would not take place, and now-a-days it was becoming very common for large steamers to carry refrigerating apparatus. Where that was the case, he did not see any difficulty in putting pipes near the bottom of the hold, through which a liquid, cooled down by the refrigerating apparatus, could be circulated, and in that way the heat could be abstracted from the bulk of the coal as fast as it was generated. He concluded by proposing a vote of thanks to Professor Lewes for his valuable paper.

The vote of thanks having been carried unanimously,

Mr. LEWES, in reply, said Sir James Douglass had answered Captain Cunningham—with whose views he did not at all agree—on the point of surface ventilation. Captain Cunningham had practical experience, and he had none, but he would rather go in a ship battened down, and with a two-inch pipe to allow the escape of gas, than with any amount of surface ventilation. If cold air were continually supplied to the surface of the coal, it would soak down and take the place of the warmer air, which had parted with its oxygen, and thus you provided the very conditions most favourable for setting up spontaneous combustion. Mr. Cobb had referred to the inconvenience of having to provide a cylinder for every eight tons of cargo, which he admitted, but it would be a great safeguard. It might, however, be arranged in another way. A large central cylinder, holding 1,000 feet, might be employed, and from that might run pipes along near the bottom into the cargo, pierced at intervals with holes closed with fusible plugs; they would melt at any point where heating took place, and allow the escape of carbonic acid. He was much obliged to Mr. Thompson for the valuable information he had given, and only differed from him when he said that the views he had put forward were at variance with those enunciated by Sir Frederick Abel and Dr. Percy. The report referred to, distinctly pointed to the oxidation of the coal as having more to do with the matter than the pyrites; indeed, he quoted the table he had given of the effects of moisture and pyrites from Dr. Percy's work on "Fuel." He should not have referred to the thermostats but for their being so universally used, and did not think there would be any difficulty with them. They should be so arranged as to give warning, not after firing had taken place, but before, so that precautions might be taken. The Chairman objected to double bulkheads, but that was a favourite idea of his; and they were absolutely necessary, if carbonic acid gas was to be used, as there must be a gas tight bulkhead between the cargo and engine-room. If the coal were battened down, which was most important, there must be no leakage of the gas into the engine-room; and the only way he knew of making a bulkhead gas-tight was, by having it double, with water between. The use of refrigerating machinery would be very effective, if the expense were not too great.

Miscellaneous.

RUSSIA AT THE CHICAGO EXHIBITION.

In a Reuter's telegram to the *Morning Post* of the 24th February, it is stated that the preparations for the participation of Russia in the Chicago International Exhibition are proceeding with every promise of the best results. The entire Russian exhibit will be directly under the supervision of the Commission appointed by the Russian Government, which has undertaken to see that the various arts and industries of the Empire shall be worthily represented. The Government has not only accepted the invitation to take part in the Exhibition, but has taken full charge of the work of organising and arranging the exhibits, and besides providing for the Government display, it invites and assures the co-operation of private exhibitors in the several fields of enterprise.

Mr. Emery Smith, United States Minister, and Consul-General Crawford, who has been appointed Commissioner of the Exhibition for Russia, have had a long interview with the President of the Russian Commission. During this conference it was intimated that the Russian Government had resolved to transport at its own expense all articles of the Russian exhibit, public and private, from St. Petersburg to Chicago, and to bring them back from the United States. Russian exhibitors have only to bring to St. Petersburg what they wish to exhibit, and the Government will assume all the rest of the cost and responsibility.

Great care will be exercised to secure a full and varied display, including carpets and other characteristic products of Central Asia. The Imperial porcelain manufactory is already at work on special designs for the Exhibition.

There is reason also to expect that the women's department will receive a handsome contribution from Russia. Minister Smith has presented to the Minister of Foreign Affairs a letter forwarded by the State Department from Mrs. Potter Palmer to the Empress of Russia, inviting the patronage and co-operation of her Majesty in the appointment of a commission of Russian ladies to direct this work. In presenting the letter, Minister Smith explained that the State Department approved the proposal, and was much interested in it, and there is little doubt that it will be accepted.

Correspondence.

BURNING OILS FOR LIGHTHOUSES AND LIGHTSHIPS.

In Mr. Boverton Redwood's letter in your issue of 26th ult., in reply to mine of 19th ult., he is good enough to say that I am entitled to be heard on behalf of the Scottish mineral oil industry; that is a claim, however, which I neither made nor make for myself.

In his reply he overlooks the only two salient points in my letter. First, in reference to the attitude of the Scotch oil companies, I must remind him that it was the Bill of 1891, and the Conferences of 1891, that were alone mentioned or referred to by Mr. Edwards, and by himself, and by me. That issue he avoids, and passes instead to the consideration of circumstances connected with Conferences of four years ago.

Secondly, I did not address myself to the general question of "test standard," as he says. What I did address myself to was Mr. Redwood's specific statement, which I was careful to repeat, viz., "That the results of experiments made by Sir Frederick Abel and himself were, that substantially it was found that a lamp might be said to be in the safest condition when the space above the oil in the reservoir was filled with vapour." My subsequent references to low test and high test oils were simply incidental to the consideration of that remarkable statement.

The question of heat development in lamps is a very important one, but so many and so varied are the producing causes, apart from the oil itself, that space will not admit of its discussion here. The simple element, *per se*, of high test or low test in an oil, counts for very little as a factor in the generation of heat. It is true that some descriptions of high test oils may develop considerable heat, but it is still more true that more heat is more frequently produced by low test oils; but under all ordinary conditions, in ordinary domestic lamps, the temperature of the oil seldom, if ever, rises to 100° Fahr.

Mr. Redwood instances two cases of lamp accidents, where it is said that high-test oils were used, one of them so long ago as 1875. Surely such isolated instances may be held to be exceptions, proving the rule in favour of high-test oils. But no reliable conclusion unfavourable to high-test oils can be drawn from either this one or the other. On turning to Sir Frederick Abel's account of the accident in the training ship *Goliath*, in 1875, we find that the evidence, for the most part, is of a negative character. The lamp had been burning all night; the boy who removed it was new to the work; the heat of the lamp was not so great as to prevent his carrying it from its position in the ship to the lamp or trimming-room before he let it drop, and the floor of this lamp-room was much impregnated with oil carelessly dropped from time to time by lads employed upon the work of lamp trimming; and Sir Frederick Abel adds, "there can be little doubt that this catastrophe has to be classed among the numerous accidents of a readily avertible kind."

In the other case instanced by Mr. Redwood, the lamp was one of the most dangerous that could be nsed, and the accident was admittedly due to the upsetting of the lamp, the burner being at the same time jerked from its position in the reservoir, allowed the oil to flow out freely over the books and papers on the floor, and naturally set fire to by the burning wick.

The doubt suggested in the quotation from Mr. Marvin's letter, regarding the allegation of the Secretary of the Scottish Mineral Oil Association in 1886, that no accidents had occurred with Scotch paraffin for 37 years, can have no influence, unsupported as it is by a particle of evidence. But practical immunity from accidents in the use of Scottish mineral oils, in consequence of the high standard of safety maintained, has been openly and constantly claimed by the oil manufacturers of Scotland during the last 40 years, and, so far as I am aware, that claim has never been challenged or its truth disproved.

Mr. Redwood refers to another point not mentioned or discussed in my letter, viz., the present legal standard. He is quite entitled to maintain that that standard is not too low; but it is one thing to do that, and quite another thing to endeavour, at the same time, to discredit high test oils in the estimation of the public.

Mr. Redwood refers to certain circumstances under which the use of oils of higher flashing-point might be advocated. It would be interesting to know which these circumstances are.

WILLIAM LOVE.

General Notes.

PATENTS AT THE CHICAGO EXHIBITION.—The United States Senate has passed a special bill enacting that no foreign citizen shall be held liable for infringing any patent trade mark or label registered in the United States if the act is performed in connection with the exposition of any article or thing at the Chicago World's Fair.

DEDICATION OF EXHIBITION BUILDINGS.—The Exposition buildings, as required by Act of Congress, will be dedicated, "with appropriate ceremonies," on October 12, 1892, the 400th anniversary of the discovery of America by Columbus. The exercises will occupy three days, beginning on the 11th and closing on the 13th with a graud ball. The Committee having the matter in charge intend to make the

ceremonies most impressive in character. The President of the United States and his Cabinet, the Senate and House of Representatives, the Governors of the several States, with their staffs, and representatives of all foreign nations will be invited to be present. The mobilisation of 10,000 militia and several thousand regulars is planned, as is also an imposing civic and industrial display. In the evenings there will be a display of fireworks, and in the park waterways a pageant of symbolical vessels, representing the "Procession of the Centuries." In the dedicatory exercises on the 12th, the completed buildings will be tendered by the President of the Exposition to the National Commission. President T. W. Palmer will accept them on behalf of that body, and will at once present them to the President of the United States, who will fittingly respond. The dedicatory oration will follow. Much attention is being given to the musical portion of the programme. In April, 1893, a grand international naval review, preliminary to the opening of the Exposition, as provided for by Act of Congress, will be held in New York harbour. Arrangements for this are now being made.

FIBRE INDUSTRY IN QUEENSLAND.—A new industry is about to be started in the Wide Bay district, Queensland. The *Melbourne Age* learns that a syndicate of nine Maryborough districts are about to lease 100 acres of land in Tinana for the purpose of growing aloe, from which sisal hemp is manufactured. They have already put in the ground over 1,000 plants, and expect to realise at least £21 per ton for the fibre when grown. This is even better than sugar cane, and can be grown with very much less trouble and a very inferior land. Walkers, Limited, are making arrangements for the manufacture of machinery for cleaning the fibre. A large quantity of twine, used chiefly for binding purposes, is imported into Australia from the United States, made from sisal hemp, which is found to be most suitable for the purpose.—*Board of Trade Journal.*

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock:—

MARCH 9.—A. P. LAURIE, M.A., "Experiments on the Durability of Modern Pigments."

MARCH 16.—TEMPEST ANDERSON, M.D., "Iceland."

MARCH 23.—GILBERT R. REDGRAVE, "Manufacture and Industrial Application of Flexible Tubing."

MARCH 30.—EWING MATHESON, "Foreign Exchange."

Papers, the dates of reading of which are not yet fixed:—

"The Fisheries Department: its Position and Prospects." By J. W. WILLIS BUND.

"The Congo State." By Captain V. LOVETT CAMERON, R.N., C.B.

"Colour Blindness." By Captain W. de W. ABNEY, C.B., F.R.S.

"Uses and Applications of Aluminium." By G. L. ADDENBROOKE.

"Egyptian Agriculture." By Professor ROBERT WALLACE.

FOREIGN AND COLONIAL SECTION.

Tuesdays, at Half-past Four or Eight o'clock; due notice of the hour will be given:—

MARCH 15.—F. A. PEZET (Peruvian Consul General), "Peru: its Commerce and Resources." CLEMENTS R. MARKHAM, C.B., F.R.S., will preside. 8 p.m.

APRIL 5.—The Rev. JOHN MCLEAN, D.D. "Manitoba and the North-West Provinces of the Dominion."

APRIL 26.—Sir EDWARD BRADDON, K.C.M.G., "The Progress of Australasia."

MAY 24.—Colonel HOWARD VINCENT, C.B., M.P., "The Extension of Colonial Trade."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

MARCH 24.—G. H. M. BATTEN, formerly of the Bengal Civil Service, "The Opium Question." Sir JOHN STRACHEY, G.C.S.I., C.I.E., will preside.

APRIL 7.—Dr. J. AUGUSTUS VOELCKER, "The Agricultural Needs of India."

APRIL 28.—Sir WILLIAM WEDDERBURN, Bart., "Reorganisation of Agricultural Credit in India."

MAY 19.—JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock:—

MARCH 29.—E. ROSCOE MULLINS, "The Decorative Uses of Sculpture." ALFRED GILBERT, A.R.A., will preside.

APRIL 12.—C. PURDON CLARKE, C.I.E., "English Brocades and Figured Silks." The LORD MASHAM will preside.

MAY 17.—GEORGE J. ROBINSON, "Decorative Plaster Work" (II.). J. HUNGERFORD POLLEN will preside.

MAY 31.—WILLIAM DE MORGAN, "Lustre Ware."

CANTOR LECTURES.

Monday evenings, at Eight o'clock:—

PROF. WILLIAM ROBINSON, M.E., Assoc. M.Inst.C.E., "The Uses of Petroleum in Prime Movers." Four Lectures.

LECTURE II.—MARCH 7.—*Petroleum Oil-engines.* —Heating of oils—Mixing and firing of charge in the internal combustion engine—Use of regenerator —Modes of governing—Practical tests—Study of indicator diagrams—Efficiency—Present economy and future possibilities.

LECTURE III.—MARCH 14.—*Oil Gas.*—Gas generator and internal combustion engine *versus* steam-boiler and steam-engine.

LECTURE IV.—MARCH 21.—*Oil Fuel and Gaseous Fuel for Steam-boilers.*—Safe heavy oils available—Different methods of burning oils—Injector-burners —Evaporative power of oil fuel.—Advantages and disadvantages of liquid fuel on steamships—Transport and storage of petroleum—Other uses of petroleum for power purposes.

BENNETT H. BROUGH, "Mine Surveying." Three Lectures.
March 28, April, 4, 11.

DR. PERCY FRANKLAND, F.C.S., "Recent Contributions to the Chemistry and Bateriology of the Fermentation Industries." Four Lectures.
May 2, 9, 16, 23.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 7...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Prof. William Robinson, "The Uses of Petroleum in Prime Movers." (Lecture II.)

Royal Institution, Albemarle-street, W.. 5 p.m. General Monthly Meeting.

Engineers, Westminster Town Hall, 7½ p.m. Mr. Stephen Sellon, "Electrical Traction and its Financial Aspect."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Mr. Oscar Guttman, "The Dangers attending the Manufacture of Explosives." 2. Drs. Evans and Wirtz, and Messrs. Cross and Bevan, "The Acid Action of Drawing Papers."

British Architects, 9, Conduit-street, W., 8 p.m. Paper on "Suggestions for the Conduct of Architectural Competition."

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 1A, Adelphi-terrace, W.C., 8 p.m. Sir Joseph Fayrer, "Serpent Worship and the Venomous Snakes of India."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. H. Blackburn, "The Portrait Painters." (Illustrated.)

TUESDAY, MARCH 8...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Victor Horsley, "The Brain." (Lecture VIII.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Professor W. Cawthorne Unwin, "Petroleum Engines."

Photographic, Great Russell-street, W.C., 8 p.m.

Anthropological, 3, Hanover-square, W., 8½ p.m. 1. Mr. Allen Brown, "On the Continuity of the Palæolithic and Neolithic Periods. 2. Rev. James Macdonald, "East Central African Customs."

Colonial Institute, Whitehall Rooms, Hotel Métropole, Whitehall-place, S.W., 8 p.m. Mr. John Ferguson, "Ceylon: its Attractions to Visitors and Settlers."

WEDNESDAY, MARCH 9...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. A. P. Laurie, "Experiments on the Durability of Modern Pigments."

Geological, Burlington-house, W., 8 p.m.

Sanitary Institute, 74A, Margaret-street, W., 8 p.m. Dr. Louis Parkes, "The Air and Water of London: Are they Deteriorating?"

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m.

Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m. Annual Meeting.

Photographic Club, Anderton's Hotel, Fleet-street, E.C., 8 p.m. Mr. T. E. Freshwater, "The Oxyhydrogen Microscope."

East India Association, Westminster Town-hall, S.W., 2½ p m. Mr. J. F. Darling, "Recent Silver Legislation and its Effect on India."

THURSDAY, MARCH 10...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. F. W. Rudler, "The Diamond."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. W. P. Ker, "The Progress of Romance in the Middle Ages. (Lecture II.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m.

Mathematical, 22, Albemarle-street, W., 8 p.m.

FRIDAY, MARCH 11 ... United Service Inst., Whitehall-yard, 3 p.m. Mr. W. B. Tegetmeier, "Pigeons for Land and Sea Service, with examples from recent experiments."

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting 9 p.m. Mr. F. T. Piggott, "Japanesque."

Civil Engineers, 25, Great George-street, S.W., 7½ p.m. (Students' Meeting). Mr. James B. Ball, "The Manufacture of Oil-Gas at the Holloway Works of the Great Northern Railway Company."

Astronomical, Burlington-house, W., 8 p.m.

Junior Engineering Society, Westminster-palace-hotel, Victoria-street, S.W., 8 p.m. Mr. Frank W. Page, "The Principles and Action of a direct-acting Pump."

Clinical, 20, Hanover-square, W., 8½ p.m.

Institute of Architecture, Dundee. Mr. T. Claxton Fidler, "The Evidence of Scientific Knowledge in the Remains of Ancient Architecture and Engineering."

Physical, Science Schools, South Kensington, S.W., 5 p.m. Mr. H. M. Elder, "Thermodynamics, and the Action of Light on Silver." 2. Prof. J. Perry, "On Choking Coils."

SATURDAY, MARCH 12...Saturday Lecture Society, Lecture Theatre, South Kensington Museum, S.W., 3 p.m. Mr. C. V. Boys, "Electric Spark Photography."

Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Lord Rayleigh, "Matter: at Rest and in Motion." (Lecture V.)

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

Journal of the Society of Arts.

No. 2,051. Vol. XL.

FRIDAY, MARCH 11, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CANTOR LECTURES.

Prof. WILLIAM ROBINSON, M.E., Assoc. M.Inst.C.E., delivered the second lecture of his course on "The Uses of Petroleum in Prime Movers," on Monday evening, 7th inst.

The lectures will be printed in the *Journal* during the summer recess.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1892 early in May next. The medal has been awarded as follows in previous years:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S., "for his great services to Arts, Manufactures, and Commerce, in the creation of the penny postage, and for his other reforms in the postal system of this country, the benefits of which have, however, not been confined to this country, but have extended over the civilised world."

In 1865, to his Imperial Majesty, Napoleon III., "for distinguished merit in promoting, in many ways, by his personal exertions, the international progress of Arts, Manufactures, and Commerce, the proofs of which are afforded by his judicious patronage of Art, his enlightened commercial policy, and especially by the abolition of passports in favour of British subjects."

In 1866, to Michael Faraday, D.C.L., F.R.S., "for discoveries in electricity, magnetism, and chemistry, which in their relation to the industries of the world, have so largely promoted Arts, Manufactures, and Commerce."

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S., "in recognition of their joint labours in establishing the first electric telegraph."

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S., "for the invention and manufacture of instruments of measure and uniform standards by which the production of machinery has been brought to a state of perfection hitherto unapproached, to the great advancement of Arts, Manufactures, and Commerce."

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, &c., "for his numerous valuable researches and writings, which have contributed most importantly to the development of food economy and agriculture, to the advancement of chemical science, and to the benefits derived from that science by Arts, Manufactures, and Commerce."

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I., "for services rendered to Arts, Manufactures, and Commerce, by the realisation of the Suez Canal."

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B., "for his important services in promoting Arts, Manufactures, and Commerce, especially in aiding the establishment and development of Science and Art, and the South Kensington Museum."

In 1872, to Mr. (now Sir) Henry Bessemer, F.R.S., "for the eminent services rendered by him to Arts, Manufactures, and Commerce, in developing the manufacture of steel."

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France, "for his chemical researches, especially in reference to saponification, dyeing, agriculture, and natural history, which for more than half a century have exercised a wide influence on the industrial arts of the world."

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S., "for his researches in connection with the laws of heat, and the practical applications of them to furnaces used in the Arts; and for his improvement in the manufacture of iron; and generally for the services rendered by him in connection with economisation of fuel in its various applications to Manufactures and the Arts."

In 1875, to Michel Chevalier, "the distinguished French statesman, who, by his writings and persistent exertions, extending over many years, has rendered essential service in promoting Arts, Manufactures, and Commerce."

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal, "for eminent services rendered to Commerce by his researches in nautical astronomy and in magnetism, and by his improvements in the applications of the mariner's compass to the navigation of iron ships."

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France, "the distinguished chemist, whose researches have exercised a very material influence on the advancement of the Industrial Arts."

In 1878, to Sir Wm. G. Armstrong (now Lord Armstrong), C.B., D.C.L., F.R.S., "because of his distinction as an engineer and as a scientific man, and because by the development of the transmission of power—hydraulically—due to his constant efforts, extending over many years, the manufactures of this country have been greatly aided, and mechanical power beneficially substituted for most laborious and injurious labour."

In 1879, to Sir William Thomson (now Lord Kelvin), LL.D., D.C.L., F.R.S., "on account of the signal service rendered to Arts, Manufactures, and Commerce, by his electrical researches, especially with reference to the transmission of telegraphic messages over ocean cables."

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S., "for having established, after most laborious research, the true relation between heat, electricity, and mechanical work, thus affording to the engineer a sure guide in the application of science to industrial pursuits."

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin, "for eminent services rendered to the Industrial Arts by his investigations in organic chemistry, and for his successful labours in promoting the cultivation of chemical education and research in England."

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S., "for his researches in connection with fermentation, the preservation of wines, and the propagation of zymotic diseases in silk worms and domestic animals, whereby the arts of wine-making, silk production, and agriculture have been greatly benefited."

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S., "for the eminent services which, as a botanist and scientific traveller, and as Director of the National Botanical Department, he has rendered to the Arts, Manufactures, and Commerce by promoting an accurate knowledge of the floras and economic vegetable products of the several colonies and dependencies of the Empire."

In 1884, to Captain James Buchanan Eads, "the distinguished American engineer, whose works have been of such great service in improving the water communications of North America, and have hereby rendered valuable aid to the commerce of the world."

In 1885, to Mr. (now Sir) Henry Doulton, "in ecognition of the impulse given by him to the production of artistic pottery in this country."

In 1886, to Samuel Cunliffe Lister (now Lord Masham), "for the services he has rendered to the textile industries, especially by the substitution of mechanical wool combing for hand combing, and by the introduction and development of a new industry—the utilisation of waste silk."

In 1887, to HER MAJESTY THE QUEEN, "in commemoration of the progress of Arts, Manufactures, and Commerce throughout the Empire during the fifty years of her reign."

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S., "in recognition of the value of his researches in various branches of science and of their practical results upon music, painting, and the useful arts."

In 1889, to John Percy, LL.D., F.R.S., "for his achievements in promoting the Arts, Manufactures, and Commerce, through the world-wide influence which his researches and writings have had upon the progress of the science and practice of metallurgy."

In 1890, to William Henry Perkin, F.R.S., "for his discovery of the method of obtaining colouring matter from coal tar, a discovery which led to the establishment of a new and important industry, and to the utilisation of large quantities of a previously worthless material."

In 1891, to Sir Frederick Abel, K.C.B., D.C.L., D.Sc., F.R.S., "in recognition of the manner in which he has promoted several important classes of the Arts and Manufactures, by the application of Chemical Science, and especially by his researches in the manufacture of iron and of steel; and also in acknowledgment of the great services he has rendered to the State in the provision of improved war material, and as Chemist to the War Department."

The Council invite Members of the Society to forward to the Secretary, on or before the 16th of April, the names of such men of high distinction as they may think worthy of this honour.

Chicago Exhibition, 1893.

MEETING IN DUBLIN.

A meeting was held in the City-hall, Dublin, on Friday, 4th inst., for the purpose of taking steps for the proper representation of Irish manufactures at the Exhibition, the Lord Mayor being in the chair.

The LORD MAYOR said the object of the meeting was to take steps to secure that Ireland should be represented at the forthcoming Exhibition at Chicago. The matter had engaged the attention of several of their public bodies, amongst others the Corporation of Dublin, which had appointed a committee, the Chamber of Commerce, which had appointed another committee, and the Royal Dublin Society which had also appointed a committee. The members of these committees had several meetings, with the result that they had invited Sir Henry Wood, Secretary of the Royal Commission, to attend on that occasion, and give them some information.

Sir HENRY TRUEMAN WOOD said he wished first to assure the meeting that the British Royal Commission were most anxious to do everything in their power to facilitate the representation of Irish industries on this occasion. He desired at once to clear away a misapprehension which might exist in some quarters—namely, that it was too late to take action in this matter. That was not at all the case. The end of last month was no doubt the time fixed for receiving applications, but that was because some time must be fixed, in order that they might get some idea of

what was likely to be sent in, and to enable them to allocate the space to those who required it. In Ireland and England a sufficient number of applications had come to make it quite certain that there would be a satisfactory representation of both countries. But the whole space was by no means occupied. There was still ample room for those who wished to come in. He did not wish them to think that there should be any unreasonable delay, but he did wish them to understand that there was plenty of time, and that if the Irish manufacturers applied without undue delay there was no reason why their requirements should not be fulfilled. America to a large extent was populated from Ireland, and America's greatest strength came from Ireland. It is natural that the chief city in the west of the States of America would be anxious to see Ireland take part in their great Exhibition. The appeal came with great force to Ireland, which sent so many thousands every year to the New World. Chicago was surrounded by an immense Irish population, and anything coming from the old country would be received with an enthusiastic welcome by them. It was feared that the expense of transit of goods 3,000 miles by sea and 1,000 miles by rail would deter many from sending exhibits, but he might say that both in England and America reductions would be made in the freights. It was then feared that the M'Kinley tariff would be a great objection. No doubt there had been some reductions in the imports into America since the tariff came into operation, but one the greatest trades in this country—the linen trade—had not suffered. Linen—at least good linen—could not be made in America, and if the Americans wanted it they must get it from this country, and if the tariff had increased for imports there, they must pay an increased price for the goods. The trade would go on, very slightly diminished for a time in spite of whatever tariff there might be. He was glad to say that the linen trade of Ireland would be well represented at the forthcoming Exhibition. Some of the foremost houses in the trade had made application for space in which to exhibit their goods. He hoped that the woollen manufactures of Ireland would be well represented. The Home Industries Association, of which Lady Aberdeen was president, had taken important action—and he hoped that in England the example would be followed—with the view of affording small exhibitors an opportunity of showing their goods—the makers of lace, and a thousand small items like that. They could not expect exhibitors of that class to go to the expense of sending their small exhibits; but if the thing was done properly, as it was being done by the Home Industries Association, there was no reason why a considerable impulse should not be given to the home industries of Ireland. He would conclude by expressing a most earnest hope that that meeting would result in a thorough and adequate representation of the more important Irish industries at the most magnificent Exhibition which this generation had seen.

The Right Rev. Monsignor MOLLOY moved:—"That it is important that steps should be taken to secure an adequate representation of Irish art and industries at the Chicago Exhibition."

The resolution was seconded by Alderman Sir HENRY COCHRANE, and adopted.

Mr. J. J. O'MEARA, T.C., moved:—"That a committee be formed for the purpose of co-operating with the Royal Commission for the purpose of securing adequate representation of Irish industries at the Chicago Exhibition." This object would, perhaps, be best accomplished by the amalgamation of the sub-committees already appointed by the Chamber of Commerce, the Royal Dublin Society, and the Corporation.

Mr. JAMES TALBOT POWER seconded the resolution, which was adopted.

Alderman ROBERT SEXTON, J.P., moved that the following gentlemen be asked to act on the committee:—"The Right Hon. the Lord Mayor, Messrs. J. J. O'Meara, T.C., Alderman Sir Henry Cochrane, J.P., James Shanks, John M'Quaid, John Beveridge, the Earl of Rosse, Sir Howard Grubb, Right Rev. Monsignor Molloy, R. J. Moss, James Talbot Power, D.L., Edmond Johnson, Hon. Horace Plunkett, Dr. E. Percival Wright, Peter White, James Brennan, John R. Wigham, J.P., E. J. Figgis, J. Malcolm Inglis, and Sir Thomas Deane, with power to add to their number."

Sir THOMAS DEANE seconded the motion, which was adopted.

APPLICATIONS FOR SPACE IN THE BRITISH SECTION.

Intending exhibitors are reminded that applications for space must be made immediately, as the allotment of space will shortly commence. Most of the available space is now occupied, and no time should therefore be lost by manufacturers desiring to be represented.

All applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, and addressed to the Secretary, as above.

Proceedings of the Society.

INDIAN SECTION.

Thursday, March 3, 1892; Major-General Sir OWEN TUBOR BURNE, K.C.S.I., C.I.E., in the chair.

The paper read was—

INDIAN SANITATION AND THE INTERNATIONAL CONGRESS OF HYGIENE.

By Surgeon-Gen. Sir William Moore, K.C.I.E., Q.H.P.

When I went to India first, in the year 1852, an acquaintance said to me, "Well, it's a very hot country, but there is one advantage, you will be able to get plenty of East India pale ale there!" evidently supposing that India was where the pale ale came from! Again, when I first went out to India, the junior medical officers were denominated assistant surgeons, a designation which has been for some time since abolished. I went to visit two old ladies. One said, "You are going to be an assistant surgeon, are you not?" to which I replied, "Yes!" "And," asked the other, "has the gentleman you are going to be an assistant to a very large practice?" To which I replied, "Oh, yes! Mr. John Company has a very large practice indeed!"

When I arrived in India, I was ordered to Ahmednuggur, in the Deccan, and it was, at that time, twelve or fifteen days' march—this being before the era of railways. The first stage from Bombay was to a place called Panwell, which was done by water, in what is termed a "bunder boat;" but a horse I had was obliged to go some distance round by land. While waiting at the travellers' bungalow at Panwell, I suppose I was showing anxiety about the non-arrival of the horse, as I wanted to continue my journey. A soldier in the bungalow, who had attained the rank of conductor in some department or other, seeing me fuming, asked the reason. "Well, sir," said he, "never mind; no one is ever in a hurry in this country."

Now, I have introduced these anecdotes because they tend to illustrate, first, the dense ignorance which prevailed in England regarding India two or three decades back; and, secondly, because the last anecdote ilustrates the ideas which prevailed in India at the time; ideas which have radically changed, for nowadays people seem to be in as great a hurry in India as in any other country. Doubtless much ignorance prevails with regard to India even now, an ignorance which has probably been intensified, rather than the reverse, by various books which have been published on the strength of a winter tour. In a healthy state of society, an Act of Parliament would be passed, that no one should write a book about India unless he or she had dwelt two hot seasons on the plains, learnt the language, and travelled through the country, far from railways, for at least 1,000 miles, as a "chota sahib," with a small hill tent, a tatoo, say two servants, and a gun.

The introduction of an Indian Section at the recent International Congress of Hygiene has shown two things. Firstly, that a large amount of interest is now taken in Indian affairs, demonstrated by the fact that four Indian delegates and Mr. S. Digby, the honorary secretary of the Indian Section, were invited to visit the Queen-Empress; also demonstrated by the number of persons attending the Indian Section, by the animated debates, by the somewhat full reports in the Press of the Indian meetings, and by the fact that Reuter sent telegrams from Mr. S. Digby to India free, in connection with the Congress. Secondly, that the Indian Government, the Indian Press, and the Indian people took great interest in the matter, demonstrated by the appointment by the Government of India and the local Governments, by the universities and colleges of India, by the leading municipalities, by the Chambers of Commerce and trade associations, by native and other societies, of some seventy delegates; also demonstrated by the numerous comments in the Indian native Press, the *Reis Ryatt* terming the International Congress "The Durbar of all nations in life science;" also demonstrated by the number of papers sent in by Indian gentlemen. Further demonstrated by the number of subscriptions received from India. Non-official India has never before participated on the same scale in an International Congress.

Among the subscribers to the Congress in India were H.H. the Maharajah of Vizianagram, £200; H.H. the Maharajah of Bhavnagar, £200; H.H. the Gaekwar of Baroda, £100; H.H. the Nizam, £100; H.H. the Maharajah of Jeypoor, £100; H.H. the Maharajah of Mysore, £100; H.H. the Maharajah of Travancore, £100; H.H. the Maharajah of Kooch Behar, £50; H.H. the Nawab of Junagurh, £18; H.H. the Rao of Kutch, £18; Rao Bahadur Runcholal Chotallel, £10; Sir Dinshaw Manocjee Petit, £10; The Maharajah Bahadur Tippera, £10. The total ssbscriptions from India, and gentlemen connected with India, amounted to upwards of £1,070.

Among the papers submitted on Indian subjects were my own, on "Sanitary Progress in India;" "The Progress of Sanitation and

Preventive Medicine in Rajpootana," by Surgeon Lieut.-Colonel Hendley, C.I.E.; "Sanitary Wants in the Bombay Presidency," by Surgeon-Major Kirtikar; "The Sanitary Condition of the Towns and Villages of the Bombay Presidency," by Dr. K. V. Dhurandur, Medical Officer and Superintendent of Vaccination at Baroda, in H.H. the Guicowar's territory; "A Note on the Hygiene and Demographic Condition of India," by Vishram Ramji Ghole, Gra. Grant Med. Coll., and Honorary Assist.-Surgeon to the Viceroy; "Village Sanitation," by Mr. Lionel Ashburne, C.S.I.; "Indian Factory Legislation," by Dr. Bahadhurji.

Now, considering all the circumstances, I think that the foregoing shows a good record. It must be recollected that the Indian Committee was an afterthought; and it had less than six months in which to interest the great Empire of India in the Congress. When the committee was formed in February of last year, and Mr. S. Digby was appointed honorary secretary, not a single delegate had been nominated or a single rupee subscribed. The work was rendered more difficult, owing to everything having to be initiated on this side; whereas, in France, Germany, Italy, &c., there were national committees who made arrangements. We had no committee in India, and there was not time to take the necessary steps to form one. Whatever success the Indian Section may have attained is mainly due to the indefatigable exertions of the honorary secretary, Mr. S. Digby, who spared neither time nor labour in the work, and there was great expenditure of both. This was recognised by the Press. In the *Times* of August 12th it is observed, "To Mr. S. Digby is wholly due the credit of organising the Indian committee, and of interesting Indian princes and others in the success of the Congress."

I propose now to briefly review the work of the Indian Section at the Congress. It was opened by the Right Hon. Sir Mountstuart Grant Duff as chairman. The first paper read was one by myself, entitled "Sanitary Progress in India." In this paper I traced the origin and advance of the sanitary department to the present time, and showed how the policy had been to connect sanitary improvement with municipal government. Various matters were mentioned which, although not coming directly under the heading sanitary, are nevertheless most important agents in the health of the people, such as improvement of the food supply by improved agriculture, and especially by irrigation, in connection with which subject the increase of fever was commented upon; the cheapening of salt; railway communication, by which better distribution of grain and of salt has been secured; the education of the people, which renders them more disposed to look favourably on sanitation; forest conservancy, which, in the future, may be expected to tend to secure a more constant rainfall, and also to prevent water running off immediately without soaking into the ground, and so lessen recurrence of scarcity and famine.*

There are very extensive districts in India which have become semi-desert from the destruction of the forest trees during generations back, principally for the feeding of camels and for fuel. So scarce is fuel in Rajpootana, especially in Marwar, that I have often seen men dismount and gather the camel's "leep" into a bag, carried for the purpose, the contents to be afterwards used for fuel.

Next, subjects more especially sanitary were discussed, viz., conservancy and village conservancy. On this subject I remarked that I was not satisfied with the system of public latrines which has been adopted, and which, for various reasons, as expressed in my paper, I regard as less desirable than the old system of the people, under certain limitations.

Next were considered drainage, local and general; vaccination; ventilation of towns and villages; water supply; the investigation of causes of disease undertaken in India; cholera; quarantine against Indian ports; the pilgrim traffic. The result of sanitary progress was then given; first, in accordance with the opinions of the sanitary officers of India, and, secondly, my own opinions. The conditions of Bombay, Madras, and Calcutta were contrasted with what they were years back. Next, the difficulties of sanitating in India were shown. Then came special remarks on military sanitation.† Lastly, I gave a chrono-

* In connection with this subject, I ventured to observe, that if the anti-opiumists succeeded in their attempts to limit the consumption of opium in India to physicians' prescriptions, thousands more would die from want during seasons of scarcity than now succumb, for opium enables people to exist on less food; and thousands more would die from fever than now do, for opium is to some extent a prophylactic against malarious fevers. I also exposed the fallacy of those anti-opiumists who have stated that famines in India resulted from so much ground being taken up for opium that sufficient did not remain for the cultivation of cereals. The fact being, that only a decimal proportion of the cultivable land in India is devoted to opium.

† Here I observed that the abolition of the Contagious Diseases Act in India was calculated to do more harm to the British soldier in India than all the other sanitary measures could compensate.

logical record of the principal sanitary improvements which had been accomplished in every province in India.

As showing progress in India, I referred especially to hospitals. The institution of hospitals in India must be regarded as one of the beneficial results of British supremacy. In ancient times, excepting during the comparatively short period of Buddhist ascendancy —from 250 B.C. to 500 A.D.—there does not appear to have been anything of the nature of a hospital. We do not find, in the *Shastras*, or *Vedic Hymns*, any reference to public hospitals. Neither were hospitals established during Mahomedan supremacy. At first, British hospitals in India were all military; but, as a measure, both of policy and humanity, medical aid was extended to natives. But, as matters settled down, and civil officials with their establishments appeared, the provision of special medical attendance became a necessity, so civil hospitals were established at all large centres. The success attending this soon led to the provision of branch hospitals and district dispensaries, many of which have been built by the liberality of native gentlemen. As showing the extension of the hospital system in India, I will mention that, in 1858-60, there were not, I believe, more than 181 institutions, treating 111,116 patients. In 1889-90, the number had increased to 1,641 institutions, treating 12,243,000 patients. There were also 25 lunatic asylums and 23 leper asylums. In addition to the above, there were 48 female hospitals or dispensaries in connection with the National Association for Supplying Medical Aid to the Women of India, established by Lady Dufferin.

Surgeon Lieut.-Colonel Hendley, C.I.E., delegate for Rajpootana, followed next with a paper on the "Progress of Sanitation and Preventive Medicine in Rajpootana." With the exception of the comparatively small district of Ajmere (Mhairwarrah), the whole of Rajpootana consists of native States, of which there are twelve. Surgeon - Lieut. - Colonel Hendley first described the ordinary condition of a Rajpootana capital. The poorer classes defile the outskirts of the town; the richer have private conveniences, generally out of repair. There are few drains. The gullies and narrow streets are rarely cleansed. Bullocks and horses are stalled in the house. Milk kine act as scavengers. The soil becomes charged with saline matters, which in time renders the water of the wells undrinkable. This, Surgeon Lieut.-Colonel Hendley states, explains the reason why every great Rajpoot principality has at least one, but often two or even more former capitals now in ruins. In the villages, Dr. Hendley states, every man does what is right in his own eyes, unchecked by the officials, by the nobles, or by public opinion, the result being entire absence of sanitation as described by Dr. Hendley.

Now it is some years since I left Rajpootana, where I was employed for a lengthened period. Even then sanitation in the capitals was dawning; and my impression certainly was, that in the capitals, at least, the condition was much improved in comparison with that described by Surgeon Lieut.-Colonel Hendley. I also remark that I do not agree with Dr. Hendley as regards the cause of the saline condition of the wells. As a rule, throughout western Rajpootana, whether in towns or not, a well of sweet water is exceptional, the ground being impregnated with saline matter. Surgeon Lieut. - Colonel Hendley next described the difficulties attending sanitation. These are chiefly low position of villages, prejudices and conservatism of the people, dirty habits, foul feeding of milk cattle, the comparatively small number of the sweeper caste among the population, &c. I wish I had time to quote Dr. Hendley on these heads, instead of referring you to his most interesting paper.

Although giving so unfavourably a description of the native States capitals, Surgeon Lieut. - Colonel Hendley mentioned much which has been effected. At Jeypoor there is an excellent constant service of water, also public gardens, a railway for the conveyance away of refuse, a conservancy establishment, latrines, main streets swept and watered, numbering of houses, and registration of births and deaths. At Jodhpoor new tanks, from which water is brought into the city, many public latrines, conservancy establishment, and public gardens. Odeypoor, Ulwur, and Kotah, are also mentioned as cities in which sanitation has advanced. Much advance has also been made in the condition of the jails of the native States. Dr. Hendley remarks that, twenty years ago, the prisoners were fastened together at night by a long chain, and men and women frequently lived together both by night and by day. Now, I had a good deal to do with the Rajpootana jails, and I do not recollect seeing the last-mentioned state of affairs, although the sanitary condition of many of the jails was very

inferior. Now, the reverse may be said of the jails of nearly all the native principalities.

I must next refer to a paper by Surgeon-Major Kirtikar, entitled "Sanitary Wants in the Bombay Presidency," which was read by Sir William Wedderburn, Bart., as delegate of the Poona Savajanik Sabha. After discussing the normal condition of an Indian village, and mentioning the sanitary regulations which it has been sought to apply to villages, Dr. Kirtikar says:—"It is the executive we want to carry out these rules. He should be a man from among the villagers, but he must be one who not only himself understands what sanitation means, and how sanitary measures should be brought to the notice of the villagers, and how he should help them and persuade them to carry out those measures, but he should also have an official status which will command respect. He must be a tolerably well-paid minor sanitary officer, just as much as the *patel* and *talati* in financial and revenue matters...... These minor sanitary officers must work direct under a sanitary officer for each collectorate. ..... It may be said that this would mean money. Of course it must cost money to improve the present state of things. Where the money is to come from is a question I need not concern myself with. One of the greatest wants of the country all over is a pure and plentiful supply of water. Every large town should have its waterworks. Where there is want of money, it should be borrowed, and the posterity, which will, in the end, be the greater gainer from such works, should be made to contribute, the town handing down the debt from father to son." Dr. Kirtikar also thinks "the stringent hand of a powerful and well-meaning Government should put down the very dangerous and sinful practice of adulterating our milk-supply with water."

The repeal of the Contagious Disease Act is rightly regarded as a retrograde movement. Vaccination, Dr. Kirtikar thinks, should be made compulsory everywhere. Now, with all deference to the writer, I opine he does not sufficiently consider ways and means; and he would rely more on direct orders from Government than is desirable. And this, although he quotes Surgeon-General Cunningham, C.I.E., who very aptly said: "In all matters connected with sanitary improvement the State may render valuable aid, but more depends on the people themselves." Neither do I think that Dr. Kirtikar has given sufficient credit, especially in the way of water supply, for what has been done. For, while mentioning the works of the former rulers of India in the way of tanks, aqueducts, &c., he does not say anything about the various towns and villages in the Presidency of Bombay which have been provided with good water supply. These are, however, enumerated in my paper.

I next refer to a "Note on the Sanitary Condition of the Towns and Villages of the Bombay Presidency, and the means for improving the same," by Dr. K. V. Dhurandar, Medical Officer and Superintendent of Vaccination at Baroda. The author first considers the situation of Indian towns which were chosen from considerations of defence rather than of sanitation. The roads of towns and villages are not in proportion to the requirements of the place, being narrow and tortuous. The dwellings are not constructed with reference to any sanitary principles. Latrines or trenches are advised for villages, but, where water is available, water carriage. The high price of salt is mentioned as preventing the proper curing of fish, which is therefore often eaten in a state of putrefaction. It is regretted that crematoria are not in use. The practice of the burial of still-born children in the rooms in which they are born has not attracted sufficient attention.

"The poverty of the people makes them impatient to municipal burdens, and no large work of reform can be undertaken without considerable expenditure. Formerly Government advanced loans from public funds or extended its guarantee to municipal loans. Government has shown considerable unwillingness of late years to follow this policy. The municipalities, left to themselves, cannot borrow money on cheap terms. People cannot bear additional taxation, and so, from year to year, large undertakings have to be put off, till the work of reform becomes, if possible, more urgent and more expensive." Lastly Dr. Dhurandar says, "Let the Government for some time more continue to instruct and guide, and refrain from undue interference or official pressure, and let it further liberally help, where help is necessary, and the results will satisfy all who feel an interest in the prosperity of the people of this country."

Now I must say that I more agree with Dr. Dhurander than with Dr. Kirtikar, for sanitation cannot be thrust on the people of India until very much remaining ignorance and apathy have been dispelled.

I next refer to a "Note on the Hygienic and Demographic Condition of India," by Vishram

Ramji Ghole, G.G.M.C. and honorary assistant-surgeon to the Viceroy of India. Dr. Ghole says the water supply, on the whole, is scanty and unwholesome, and that the people are mostly indifferent to its purity. Generally speaking, the people are badly housed, and ventilation is lamentably defective. A most unsanitary, injurious, and filthy practice exists in some parts of the country of having privy-pits, which are seldom, or never cleansed. In the matter of food, the people of India are badly off, owing to general poverty, "and they have usually to pass their days on scanty fare." The people are also scantily clothed. Drainage is referred to as very defective. Burial-grounds in large cities are injurious to the population. The practice of housing cattle, horses, asses in the dwelling-house is condemned. Dr. Ghole says that drinking is on the increase; that the use of Indian hemp, ganga or bhang, is very common; that syphilis is on the increase; that Hindoo bathing is merely nominal; that the sedentary habits of large classes act perniciously; that early and unequal marriages deteriorates race; that enforced widowhood has entailed a fearful amount of misery; that the filthy water used at Jatras and fairs and places of pilgrimage—which the pilgrim delights to bathe in and drink—is the cause of the outbreak of diseases; that caste demoralises the people, and checks the intellectual growth of the population. Lastly, Dr. Ghole says, "The missionaries have done much good in this direction, by diffusing a knowledge of the laws of sanitation. They are teaching the people, wherever they can, the simple rules of health—the necessary conditions of physical well-being."

Mr. Lionel Ashburner, C.S.I., formerly one of the Honourable Members of Council of the Government of Bombay, also contributed a paper on "Village Sanitation," in which he truly pointed out, that the Act of the Bombay Government, passed last year, for providing for the better sanitation of villages would fail to secure the necessary funds for the purpose. Mr. Ashburner rightly considers that the trench system is best for small villages.

Mr. Burjorjee Byramjee, Member of the State Council and head of the Medical Department of Bhavnagur, contributed an interesting note on the topography and sanitation of Bhavnagur, showing that sanitary measures have advanced in this native State. "How can the Masses in India be made to comprehend the Elementary Principles of Sanitary Science?" was the title of a paper by Professor Jamsetjee Unvala, Principal of the Samaldos College of Bhavnagur. The Professor thinks that a knowledge of sanitary science should be made compulsory at the school final examination. Public bodies, he thinks, should be asked by Government to organise systems of lectures on sanitary science, which, on the principle that appeal to the eye has a more lasting effect than appeal to the ear, should be illustrated by the magic-lantern.

"Some Practical Measures needed for the Development of State Hygiene in India" were noted by Dinshaw Ardeshir Sahib of Baroda, among which the appointment of a sanitary Member of Council in India, and the establishment, by Government, of a hygienic journal, are advocated.

An excellent paper on "Sanitation in Ceylon" was forwarded by Dr. Solomon Fernando, which shows that much improvement has taken place in that island.

Other papers, which might have been appropriately read in the Indian Section, were—"The Prevention of Fever in India," by myself, read in the Section of Preventive Medicine; "Sanitation in India," by Mr. Baldwin Latham; "The Water Supply of India," by Brigade-Surgeon Pringle; "Enteric Fever in the European Army of India," by D. Lane Notter, Professor of Military Surgery, Netley; "Hygiene for the Zenanas of India," by Surgeon-General Francis; "The Suitability of Tropical Highlands for European Settlement," by myself. All these were read in different Sections.

An important subject brought before the Congress was the Indian factory legislation question, Mr. Holt-Hallett taking one view, and Dr. Bahadhurji, of Bombay, the opposite. If there were sufficient time to analyse what was said, I think it would appear that Mr. Holt-Hallett overstated the case of the mill hands by selecting chance incidents, and by holding them forth as ordinary occurrences. Whether or not it is correct, as lately stated by Mr. Cotton, of Bombay (*Times of India*, Dec. 19), that Mr. Holt-Hallett had never been in an Indian mill, and knew nothing of the conditions of labour, as conducted in Indian mills I have no means of ascertaining. It is certain, however, that Dr. Bahadhurji knows all about the mills of Bombay; and he expressly states that the mill-hands, as described by Mr. Holt-Hallett, do not exist in Bombay, or in any other part of India. Dr. Bahadhurji

says :—" With these women restricted hours does not mean restricted labour. Abstract principles are applicable to ideal States, but they should be modified to suit actual conditions." The conclusion to be drawn from the papers on "Factory Employment in India" is, that factory legislation should rest with the Indian authorities rather than with the Home Government, or even the Imperial Parliament.

Dr. Bahadhurji has certainly recently scored, for the female mill hands of Ahmedabad have made a direct appeal to him to try and obtain for them exemption from the eleven hour rule, which came into operation on the 1st of January.

I am sorry I cannot review the animated debates which took place on these papers.

Now, I cannot assert that what has been said as regards Indian sanitary defects is, as respects many places, either overdrawn or incorrect. But I differ altogether from some of the conclusions which have been drawn therefrom, and which were aired at the recent Venice Sanitary Conference.

Certain delegates at Venice reiterated as facts what I believe to be fallacies. They still asserted, that as a consequence of defective sanitation, India is the manufactory of cholera, and that cholera is conveyed to Europe, either *viâ* the Suez Canal or by a much more circuitous route overland, through the countries between India and Europe. To support his views, one delegate quoted certain speakers at the International Congress of Hygiene, who expatiated on various Indian deficiencies. The delegate also quoted some official reports to a similar effect. But the great advances which have been made in Indian sanitation were altogether ignored. Yet there are no three large cities in Europe where greater advances in sanitation can be shown than in the cities of Bombay, Madras, and Calcutta during the last two decades. And there are numbers of towns and villages in India, the sanitary condition of which would compare favourably with that of numbers of towns and villages in Great Britain; which would compare still more favourably with a greater number of villages and towns on the continent of Europe; and which would compare most favourably with towns and villages of China, Afghanistan, Persia, Arabia, Turkey, and other Eastern countries.

In Mrs. Bishop's recently published book, "Journeys in Persia," there are various descriptions of unsanitary towns and villages, of which I will quote one. In Kizil-Rohat, "the dirt is appalling, even in this dry weather. In spring the alleys of the town are impassable, and people whose business calls them out, cross from roof to roof on boards. Pools of filthy water, loathsome ditches with broad margins of trodden slime full of abominations, ruins of houses, yards foul with refuse, half-clothed and wholly unwashed children . . . . a well-built brick bazaar, more mud and dirt, some ruinous caravanserais, and near the extremity of the town is the horrible one in which I am now, said to be the best, with a yard a foot deep in manure and slush, in the midst of which is the well, and around which are stables and recesses for travellers."

It would, therefore, appear that if continental authorities require unsanitary conditions in eastern countries, as the breeding ground of cholera, they need not project so far east as Hindustan. They might reasonably attribute cholera to the total absence of sanitation in the countries between Europe and India, where the climate is favourable to the disease, and where doubtless much more cholera occurs than we even hear of. But preaching to the shadowy governments of the countries named the necessity of sanitation, in order to prevent the spread of cholera into Europe, would be too absurd. Whereas the Government of India is a prominent powerful fact, with Europeans at its head, and hence to be impressed by European opinion. Some cynic observed that there is always a satisfaction in discovering a blot on one's neighbour's game. There may therefore be some gratification from attaching to the possession of the great Eastern Empire the odium of sending cholera to Europe as a consequence of the want of sanitary care. In my paper on "The Progress of Sanitation in India," it was shown how, in many different manners, the Government of India had endeavoured to meet the views of previous sanitary conferences; almost the only absolute refusal being, that the Indian Government declined to stop pilgrimage in India, or to harass the pilgrims unnecessarily at the instance of the Congresses.

It is not in the power of the Indian Government to put a stop to the cholera in India. Owing to the climate, food, defective personal hygiene, the demands of creed, in short, to general environment, cholera, in one phase or other, is always present in India. But that this Indian cholera is the source from which European epidemics arise I do not believe. Endeavours have been made to connect more or less vague reports of cholera in Beelochistan,

in Afghanistan, in Arabia, in Persia, in Turkey, &c., with Indian cholera in order to support the theory of a westward progress of the malady. Had similar reports been collected from countries east of India, there would doubtless have been similar reason for assuming an eastward progress of the disease.

Amongst a mass of theory, two facts, as I regard them, stand prominently out. Firstly, that the incidence of cholera is on the most unsanitary localities; secondly, that cholera, in the guise of *cholera nostras*, and summer diarrhœa, is ordinarily present in most countries. I have elsewhere* recorded cogent reasons for my belief that *cholera nostras*, summer diarrhœa, and cholera, are the same disease. Continental delegates appear, however, to think that if cholera were prevented in India by sanitary work, there would be no necessity for sanitary work in their own countries, as there would be no cholera to guard against. I fully believe, however, that if there were no cholera in India, European epidemics would occur just the same, whether originating or revitalised in the utterly unsanitary towns and villages of the countries between India and Europe, or whether, as more probable, originating or revitalised as *cholera nostras* in unsanitary European places. Continental writers are fond of referring the origin of cholera to the shrines and places of pilgrimage in India. In former years cholera did frequently occur at these gatherings; but owing to careful sanitary preparation and arrangements, we can now safely say, cholera most probably will not occur. It is somewhat curious that, while certain authorities have not hesitated to urge the Government of India to adopt such measures as would practically stop pilgrimages in India, such a proposal as regards pilgrimages to Mecca has never been even hinted at. If sanitary measures were carried out at Mecca in the comprehensive manner they are conducted at large Indian pilgrimages, cholera would be exceptional at Mecca, as it is now at Hindoo shrines; and we should not have to lament that more than one-third of the pilgrims proceeding from Bombay, on the Haj to Mecca, never return. But the principal endeavours are devoted to preventing a possible danger from India.

Ordinary sanitary measures may be summed up as improved water supply, removal and disposal of filth, surface and subsoil drainage. Someone observed that morals differ in different countries, in different towns, in different streets, even in different Acts of Parliament. What is moral in London is immoral somewhere else, and *vice versa*. As with morals, so with sanitation. Sanitation, as sanitarians understand it in England, cannot be indiscriminately thrust on India—climate, soil, habits, customs, creed, ignorance forbid. Of the three ordinary sanitary requirements mentioned above, the supply of pure water is the only one generally applicable to India. Although much has been done in this respect, much more remains to be done, especially at railway stations and at places of pilgrimage. And I am sure I carry with me the sympathies of all educated Indians, when I say that punitive measures against those who defile water should be made more severe; for it has been shown, from the *shastras* and writings of Manu, that present customs with regard to water are at variance with ancient precepts. The second ordinary sanitary measure mentioned, *viz.*, removal and disposal of filth, cannot always be conducted in India as is supposed to be best in England. In large cities separation of sewage and storm water is essential. For no sewers adapted for fæcal matters would meet the occasional extraordinary fall of rain occurring in the East. On the other hand, unless there is plenty of water for flushing, which is not the case everywhere in India, sewer pipes soon become abominations. But the conservancy of small villages is perhaps the most difficult question of Indian sanitators, and I have already mentioned that I consider the public latrine system which has been instituted a mistake, for one reason, because it induces the people to make more "kulkuars" (private privies) in their own houses. As regards the third ordinary sanitary requirement, surface and sub-soil drainage, although the former is generally applicable, sub-soil drainage is not so generally applicable. Subsoil drainage is not applicable to those sandy countries where only a few inches of rain fall, for the sand immediately absorbs the rain like a sponge, and although it is damp and cold a very short distance from the surface, this would not be obviated by drainage, the moisture not being sufficient to escape from the holding sand by oozing. Subsoil drainage again, as pointed out by Surgeon-General Cornish, C.I.E., is not applicable to localities—as the Carnatic for instance—where they do not suffer from too much rain, but from excessive dryness of the

* "British Medical Journal," 1889.

soil. During the prolonged period of dry weather, subsoil drains become blocked by deposits of ants, lizards, rats, &c., so that when the drains are really required no water flows through. This, it may be said, is a matter of supervision, and so it is to a certain extent. But to ascertain the potency of any larger extent of subsoil drainage is no easy matter, and deposits of the kind mentioned occur very suddenly. As a matter of fact, when the Indian monsoon bursts, and heavy rain falls, many subsoil drains overflow.

I have made these remarks with the view of first showing to Indians that some sanitarians, at least, do not believe in the efficacy of thrusting British sanitation on India, without consideration of peculiar circumstances. And, secondly, with the view of showing those—chiefly foreigners—who appear to think that India can be easily sanitated on European lines, that this cannot be done.

The wholesale abuse which has been heaped on India, as the origin and home of cholera, owing to defective sanitation, is not deserved. From what has been written, one might imagine that the Indian air was what Voltaire scornfully called the atmosphere, "A blue and white mass of poisonous exhalations." And the habits of the Indians, although as respects personal hygiene especially very detrimental to health, are not, when climate is considered, so universally destructive as has been portrayed—remindihg one of Bishop Heber's description of the land where "every prospect pleases and only man is vile."

In the consideration of sanitary matters, as in the consideration of various other subjects, climate is not always taken into adequate account. But climate, as a factor of habits and usages in one part of the world that are incomprehensible to those living in other parts, plays a *rôle* that is not sufficiently appreciated and understood. Whether it be the question of diet, dress, or habit, climate exerts its influence in no uncertain manner. It is the Englishman's privilege to grumble, and it is the Englishman's privilege to run down and decry all things excepting his own personal possessions. The practice, like lawn tennis, cricket, racing, and wearing top hats, has been imported to India. I am quite sure that some of the unsanitary descriptions contained in Indian sanitary reports picture the worst instead of the ordinary conditions. As regards the requirements, which are, indeed, numerous, it is only right that such should be reiterated and again and again brought to notice, so that, when pecuniary means are available, they may be supplied. But these unsanitary descriptions, and these reiterations of wants, are what attract the notice of those who believe in India being the home of cholera, and in the conveyance of the disease to Europe from India. What has been done is not brought out sufficiently prominently: and I look forward to its being demonstrated at future Congresses that India is not so much behind in sanitation as is generally believed. It is not so very long since Dr. Acland observed that the labours of the Indian Sanitary Department have equalled the best work in any country.

At the close of the Congress, Sir William Wedderburn proposed the following resolution, which was seconded by Sir Douglas Galton:—

"That, looking at the interest shown by India in the Hygiene and Demographic Congress, and considering the probability that other tropical countries and colonies would take a similar interest in future Congresses, if a more prominent position were given to the consideration of subjects in which they are specially interested, this meeting recommends to the Permanent Committee that, in future Congresses, a Tropical Section be formed, with a view to a more full discussion of questions affecting sanitation and the origin of disease in tropical countries."

The first idea was to form an Indian Section, but this was, necessarily, soon given up, because it was felt that, when the Congress meets in other countries, the interest felt in India would not be sufficient to justify an Indian Section. But a Tropical Section is different, because other countries have tropical possessions, the sanitation and diseases of which might well be compared with those of India by delegates at future Congresses.

DISCUSSION.

Surgeon Lieut.-Colonel HENDLEY, C.I.E., said it had been said that the Government of India might have done more for the Hygienic Conference by deputing paid experts from India to attend the discussions, but the paper just read had sufficiently disposed of that objection, and he thought neither the Secretary of State, the Press, nor the taxpayers would have supported any such expenditure of public money. The Congress was intended, in the first place, to sum up what had been done in the past, so that it might be of use in the future, and also to popularise the subject of Indian hygiene; and he thought the money which would, in that case, have been spent might be better employed in future in holding small congresses of engineers, and medical and civil officers, such as Sir Edward Buck had held

from time to time, for the Agricultural Department, in various parts of India. A good deal might also be accomplished by affording facilities to medical officers to go about and see what was done in other large towns. He had found this of very great use in suggesting schemes for the sanitation of Jeypore. Frequently, in India, very much was done over and over again for want of a little knowledge. Sir William Moore had somewhat criticised the paper he read at the Congress with regard to the present condition of the native capitals and large towns of Rajpootana, but he (Dr. Hendley) might say that he wished to accentuate the good which had been done in the native States, chiefly by the support of the native princes themselves. But though an immense deal had been done there was still an immense deal to do. Though very great improvements had been made in the capital towns, in the suburbs and country towns things were nearly as bad as before. In some of these towns there were 30,000 or 40,000 people, and nothing whatever had been done. Twenty-one years ago he went to Rajpootana, and served under Sir William Moore, and no one was better aware of the immense deal of good which had been done under Sir William's advice than himself, and he looked upon him as the father of sanitation in that province. As regards the wells in Jeypore, sweet water was found in many of them outside the towns, and in some within the large towns, yet within 200 or 300 yards of these there were wells containing very saline water. A proof that the saline water was due to the insanitary habits of the people was found in the fact that many of the old towns were said to have been abandoned principally because the water had become foul. When these towns were first built the water was sweet. With regard to the prisons, great advances had been made in Rajpootana, but still in outlying places defects existed. Only ten years ago he saw in a jail a chain on the floor, which was used every night to fasten the prisoners together; and he knew of one or two places where men and women, although not actually living in the same cell, were quartered in cells which opened into the same yard. It had been suggested that the *hakeems*, and *baids* might have been called in to give their opinion; but, as practical sanitarians, they knew that nothing would ever come of such a suggestion. The other day, a civilian, who had been a commissioner, told him that, when the *hakeem* in a large native capital died, the son, who had only been practising the profession two or three years, was installed in his place. A good many people objected that he had no knowledge, but it was said that did not matter, as his father had had sufficient for him, and things would go on as well as ever. One of the great deficiences was the want of good subordinate officials. The Prime Minister of Jeypore told him that it was almost impossible to do much good in the villages, because there were no subordinates who believed in the efficacy of sanitation, and who were sufficiently educated to carry out the orders of the durbar. Some attempts had been made to educate these men, but it was a very difficult task; and he feared civil surgeons would find it almost impossible, so much of their time being taken up in other work. There was a tendency now to employ them in matters of detail, leaving them very little time to look after the health of the general population. In some quarters it seemed as though far more attention was paid to criminals than to honest people; and when a man had been spending three or four hours in petty details in a prison, even weighing the prisoners, he had not much inclination to lecture on sanitation. He thoroughly agreed, in the main, with Sir William Moore, and especially that not enough credit had been given to the officials of the Government for the enormous strides which had been made.

Sir DOUGLAS GALTON, K.C.B., F.R.S., as President of the Organising Committee of the International Congress, said he had listened with great pleasure to this paper, summarising so well the work done in the Indian Section. He thanked Sir William Moore for the care he had taken to answer the objections of foreign sanitarians on the origin of cholera in India, and its extension from India to Europe. It was quite certain that we were suffering very much from the fact that the great improvements in sanitation which we have accomplished in India during the last quarter of a century have drawn attention to the sanitary conditions of that country, and have led foreign sanitarians to fix on India as the birthplace of cholera, and to remain contended with their own insanitary conditions, and make use of India as a reason why they should not improve their own towns, but should rather endeavour to oppress our trade by means of quarantine. Some few years ago the Government of India adopted a measure which he thought would have a very far-reaching effect on the improvement of sanitation in that country, viz., the creation of Sanitary Boards in the different provinces; and that morning he had been looking throngh a series of reports, now in the India-office, from the various provinces, on the work of those Boards, showing the places in which they had been established, and the places where they were just commencing. What struck him was that these Boards had chiefly hitherto confined their work to the municipalities rather than to the village populations; and considering that villages in India in some provinces numbered hundreds of thousands, and that some of these were very large, and that therefore an enormous population was concerned, it was to be hoped that the Sanitary Boards would turn their attention to this matter as soon as possible. Village sanitation really meant guarding carefully the water supply, cleanliness, and conservancy, rather than constructing expensive works such as many of the towns and municipalities required. In conclusion, he thanked Sir William Moore for his valuable paper.

Surgeon-General CORNISH said he agreed with the views put forward in the paper. For many years he had been Sanitary Commissioner for the Presidency of Madras, and afterwards Surgeon-General and Chief Sanitary Officer, and it fell to his lot to ascertain the condition of the people. There could be no question that complete provision had been made with regard to the sanitation of the towns in the Municipal Bills of 1884, but the sanitation of villages had yet to be taken up. Before he left India he was a member of a committee for revising the Local Board Acts, which were revised in 1884, and passed. With regard to the Presidency of Madras, arrangements were made for the union of villages covering a certain area and population for purposes referred to by Sir Douglas Galton, keeping the water supply in a pure state, and cleansing the villages, but he did not know how the Act regarding the union of villages had worked —he feared rather badly, because the people were not yet ready to take advantage of the power they had of collecting money for the purpose of cleanliness. It was a work of time to make them understand the great importance of these things, but no doubt some day the people themselves would become as interested in their own sanitary condition as their rulers were. Anyone who had a knowledge of the people of India knew it took a long time to get into their heads the notion that filth and the pollution of water were injurious.

Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., said that Sir William Moore had given them an admirable *précis* of the work of the Indian Section of the late Congress of Hygiene and Demography, and had not only conferred a great favour on the Society of Arts in preparing it, but had done a great service to the Congress; and he hoped that the Council of the Society would sanction the presentation of a large number of copies of the *Journal* of the Society in which the paper appeared, to the Secretary of State, for distribution with the volume of the Report of the Congress relating to India, throughout that country. Regarding the subject of the paper, he was not entitled to offer any criticisms; but both Sir William Moore and Dr. Hendley had been rather sweeping in their condemnation of Hindu medicine and hygiene, and he took the opportunity to offer a few remarks of respectful protestation against their apparent prejudice on these points. Medicine was not a science, but an art, the successful practice of which depended very much on the personality of the artist, and the patients' faith in him. On his first appointment to the medical charge of a native regiment, he gave his patients the option of having in a native *vaid* to attend them; and, at that very moment, it had come into his recollection, that in taking charge of the hospital of the 3rd Bombay Native Infantry at Sholopore, in 1855-6, a *havildar* was transferred to his care dying of fever. Every attempt to produce perspiration having failed, he at once consulted the man as to his wishes, and he said, "Stop all this English treatment, and call in one of our own *vaids*." He did so, and within twenty minutes of the initiation of the prescribed incantations, the patient broke out into a profuse perspiration, and rapidly became convalescent. Dr. Hendley had whispered to him that had he waited twenty minutes he would have saved his own credit. So be it; but, after that, he always took free advantage of the experience of the *vaids*, and, when ill himself, always called one in. They amused him, and stuffed him with all sorts of out of the way lore; and, as he had no faith whatever in therapeutics proper—except in the etymological sense of the word—he certainly got as much benefit from them as he would have received from any English practitioner. On the other hand, he had the strongest confidence in Western surgery and hygiene. But, even with regard to the latter, the Hindus could teach us some lessons; in the disposal of their dead by cremation, for instance. The practice was repugnant to Western sentiment, but, from a scientific point of view, it was preferable to burial. He was also not indisposed to defend the Hindu practice of *sati*, or widow burning, and infanticide. The net result of our sanitary improvements in India had been to enormously increase the population; and the worst of all insanitary products was a superfluous human being. This question of the prodigious increase of the population, both here and in India, would, at a no distant future, have to be frankly faced and ruthlessly resolved. The true ideal of sanitation was not a reduced death-rate, but the highest health, wealth, and happiness of the living mass of able-bodied and capable working adults.

Lieut.-Colonel A. T. WINTLE, late R.A., suggested that the word hygiene ought to be defined. He had studied the question for some years, and, from what he had read, he gathered that there was a good deal of difference of opinion about it. To him it meant simply pure air, pure water, pure food, and being temperate in all things; but some included vaccination under hygienic measures, though, according to the highest authorities, vaccination meant the introduction of a poison into the system.

Sir GEORGE BIRDWOOD protested against anti-vaccination theories or any other fads being introduced into the discussion, or there would be no end to it, and these could only be discussed properly by medical men.

The CHAIRMAN hoped Colonel Wintle would confine his remarks to the subject of the paper.

Lieut.-Colonel WINTLE suggested that something might be learned from the old writings of the Brahmins, whose moral philosophy, according to Sir W. Temple, consisted in the prevention of all diseases, from which they imagined all perturbation

of mind arose, and who considered it a disgrace to be ill. He belonged to the Vegetarian Society, which advocated hygiene, and he had, like others, found out the secret of health for himself under somewhat trying circumstances; but they were teaching a doctrine which, according to the ordinary acceptation of the term hygiene, was harmful to the State, because they taught that vaccination was injurious, whilst they sought to encourage self-denial and all the higher moral qualities. He believed they were all aiming at the same result, though they differed as to methods.

The CHAIRMAN said he had never heard a more clear or concise paper than the one now read, and he had really very little to add to the discussion on it. As Chairman of the Indian Committee of the International Congress, he could corroborate all that had been said by Sir William Moore with regard to the prominent part taken by the Indian Section, thanks mainly to the indefatigable exertions of Mr. S. Digby, the encouragement given by Sir Douglas Galton, and the hearty response made by the Government of India and the official and non-official classes to the appeals addressed to them. The native princes, moreover, gave practical proof of their interest in the Congress which had, on its part, been of great value to India. An interesting account had been given by Sir William Moore of the progress of sanitation in India, and he quite agreed with him that there were no three large cities in Europe in which greater advances had been made than in Bombay, Madras, and Calcutta, while there were numbers of towns and villages in India which would compare favourably not only with the towns and villages on the continent but with those in England. He could himself look back to the time when both Europeans and natives depended for their water supply on putrid tanks and filthy wells; but now, if he was correctly informed, to the principal towns and villages a supply of pure water came through pipes from well-built reservoirs; and from this reform alone there had been a large decrease in the death-rate. No doubt much remained to be done, but it was reassuring to remember that taking the Europeans troops alone, while some thirty years ago the death-rate was 69 per 1,000, it was now only 14; and the death-rate in the civil population showed equally good results, arising chiefly from sanitary precautions. Both as a Society and as individuals, they should do all they could to strengthen the hands of the sanitary authorities in India and at home; not by making exaggerated misstatements so common in this country on such matters, but in interesting and educating the public mind, as the reader of the paper had done, by careful statements of fact. He was disposed to agree with Sir William Moore that the abuse which had been heaped on India, as the origin and home of cholera, was not altogether deserved. It was in no way proved that the heavy epidemics which afflicted this country in 1848, 1855, and 1865 came from India. On the other hand, it had been shown by Sir Joseph Fayrer, in his presidential address at the recent Congress, that it was not cholera but fever which was the prevailing disease in India; for while the deaths from cholera in a certain typical year named only amounted to about $1\frac{1}{2}$ per cent. in the European troops and 4 per cent. in the civil population, the deaths from fever were 5 per cent. amongst the former, and 17 per cent. in the latter. It was, therefore, rather hard to accuse India of being the home and hotbed of cholera, and to assert that cholera in Europe always came from India. He concluded by moving a hearty vote of thanks to Sir William Moore.

The vote of thanks having been carried unanimously,

Sir WILLIAM MOORE, in reply, said he was quite aware that chains were formerly used in jails in the native States; he had seen them many times, but he did not know of any jail in which men and women were kept together at night. Sir Douglas Galton had referred to the Sanitary Boards recently instituted, and though he (Sir William Moore) had not mentioned them in the present paper, he did so in the paper he read at the Congress, and referred to the benefits likely to accrue. It was probably quite true, as Surgeon-General Cornish had said, that much remained to be done with regard to the sanitary condition of the villages in Madras, and in Bombay also; but Bombay was rather better than Madras, and always had been. The cases mentioned by Sir George Birdwood he should describe as instances of faith-healing; and though Sir George Birdwood did not believe in medicine, he thought, if Sir George took a considerable quantity of quinine, he would find his head buzzing; and, if he took plenty of Epsom salts, something else would happen. To his remarks on infanticide and suttee, he might have added the burial of lepers; and, though he (Sir William Moore) did not like to say much about it, he might say that, if it were desired to reduce the population, some effect might be produced by stopping the use of opium. Colonel Wintle wished to know what hygiene meant. He presumed it meant the health of the body personally; and sanitation meant the health of the country generally. He did not think much useful information could be obtained from the old writings of the Brahmins, as they would not have anything to do with sick people or hospitals for fear of pollution. With regard to water, there had been hundreds of thousands of wells either rebuilt or repaired and thoroughly cleansed within the last decade or two. Two great obstacles to sanitary progress were, on the one hand, the exaggerated statements which had been referred to, and, on the other, the impracticable suggestions made by some sanitary officers, which they knew could not be carried out.

Colonel THACKERAY, R.E., C.B., V.C., added, as showing the advance which had been made in sanita-

tion in India, that some years ago, in his experience, one regiment alone lost 200 to 300 men from cholera, and two years after it lost 400. In 1867 200 men, women, and children died in a month from the same disease; but now cholera was almost entirely stamped out amongst the troops through the improved accommodation which had been provided.

THIRTEENTH ORDINARY MEETING.

Wednesday, March 9, 1892; Professor W. CHANDLER ROBERTS-AUSTEN, C.B., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Chase, George B., 234, Beacon-street, Boston, Mass., U.S.A.
Formoy, James Arthur, Lestelle, Forest-hill, S.E.
Goodridge, Captain John James Lewis, Portswood, Southampton, Hampshire.
Mallet, Robert Trefusis, 1, Philbeach-gardens, South Kensington, S.W.
Wye, Thomas Henry, Brooklands, Leytonstone, Essex.

The following candidates were balloted for and duly elected members of the Society:—

Blanchard, Mark Henry, Bishop's Waltham, Hants.
Courtenay, J. Irving, M.A., 1, Essex-court, Temple, E.C.
Farlie, John Burke. 128, Eglinton-road, Plumstead, Kent.
Goodenough, Lieut.-General William Howley, C.B., Blomefield-house, Shooter's-hill, Kent.
Langton, Alfred, Deptford Pier, S.E.
Macpherson-Grant, John D.L., Ballindalloch, N.B.
Wells-Smith, Henry, 8, Norfolk-row, Sheffield.

The paper read was—

ON THE DURABILITY OF MODERN PIGMENTS IN OIL.

By A. P. LAURIE, M.A.

Professor Church, in his recent book on the "Chemistry of Paints and Painting," has drawn up a selected palette of twenty-five pigments suitable for oil painting. He divides them into two groups.

Section I. contains:—

Flake white.	Vermilion.
Cadmium yellow.	Madder carmine.
Cobalt yellow.	Light red.
Yellow ochre.	

Viridian.	Raw umber.
French ultramarine.	Cappagh brown.
	Ivory black.

Section II. contains:—

Raw sienna.	Purple madder.
Naples yellow.	Madder brown.
Baryta yellow.	

Green oxide of Chromium.	Cobalt blue.
Terre verte.	Prussian blue (insol.).
Malachite.	Burnt sienna.
Emerald green.	Caledonian brown.

This selected palette is the outcome of many years of experimenting, and of useful observation of the behaviour of pigments. It is also, I believe, sufficiently complete to supply all that is needed in painting a picture. On the other hand, it cannot be regarded as final. Doubtless, as our knowledge increases, certain pigments will be excluded from this list, and others introduced. It will be necessary to subject it to a careful and detailed criticism from time to time. It has seemed to me, however, better to confine myself to this palette than to conduct experiments over the whole range of pigments, although there are pigments which have been excluded, and which are worthy of another trial.

Among the reasons for doing this, I may point out that there is a tendency to useless repetition in the experiments on this subject, and to proving again and again that certain pigments are fugitive. Surely the fate of certain colours has been finally settled, and they need be no further considered.

I have also been limited in range by the fact that I have set myself to prepare most of the pigments experimented upon, and to prepare them in such a form that they should be equal in colour, &c., to the commercial specimens. The importance of doing this is obvious. We can only hope to arrive at accurate knowledge on this subject by preparing the pigments experimented upon, and knowing their history and what they contain.

This is a most laborious task, however, as published recipes are almost useless, and months of experimenting were usually necessary before a single pigment mentioned here could be satisfactorily produced.

In order to make the paper complete, the recipes used in the preparation of the pigments should be published in full. This is impossible at present, though they are all carefully recorded, and will ultimately be made public.

This paper then is merely a few notes on Professor Church's palette, not pretending to exhaust the subject, and to be added to, from time to time, as fresh results are obtained.

Let us begin our illustration of this palette by selecting from it the pigments which require careful preparation and careful testing before being finally included. They are—Cadmium yellow, cobalt yellow, vermilion, madder carmine, French ultramarine, Naples yellow, baryta yellow, purple madder, madder brown, malachite, emerald green, Prussian blue—all these pigments are artificial, except malachite, which is of little importance; and much will depend on the method of preparation, careful washing, exclusion of dangerous impurities, and freedom from gross adulteration. The other pigments in the list are permanent, if genuine; and therefore all that is necessary is to look out for adulteration.

To take, then, the yellow pigments mentioned in the first column, and to begin with *Cadmium Yellow*, careful readers of Professor Church's book will find that he refers to only one shade of this yellow as being perfectly safe, an orange-yellow shade. The pale cadmiums are notoriously fugitive, and contain free sulphur, while the deep orange cadmiums seem apt to change into the yellow varieties.

I have been trying, myself, to obtain a cadmium of a pure light yellow, which shall contain no such objectionable constituent as free sulphur, and shall also be molecularly stable. I have been preparing some lately which I subject to a dull red heat before grinding. This ought to increase molecular stability, and would, of course, prove destructive to pale cadmium, made the usual way. I do not feel justified in publishing the process as yet, but I think the pigment is worthy of a trial, as it ought to be stable.

Cobalt Yellow (*Aureoline*).—This pigment (a nitrite of cobalt and potassium) I have prepared from a recipe very similar to the one given by Professor Church. I find, after thorough washing, and grinding in oil, that it is not affected by twelve months' exposure out of doors towards the south; so that, as far as my tests go, I can confirm Professor Church's good opinion of it.

Yellow Ochre.—I have recently had my attention directed to a most objectionable adulteration of yellow ochre with lead chrome yellow. Out of seven samples of "Oxford ochre" sent me by wholesale dealers in pigments, two contained chrome yellow. One of the two consisted very largely of whitening, tinted with chrome, and mixed with a small quantity of a pale ochre. The result was a sample which looked as bright as the best samples of genuine Oxford ochre. Professor Church mentions adulteration with yellow lake—I have never yet met with a case of this.

Vermilion. — I have described at length elsewhere my experiments on this pigment. I find many English samples to contain alkaline sulphide, and prefer genuine Chinese vermilion. The following are the per-centages of ash found in different samples of Chinese vermilion obtained direct from China :—

(1)	(2)	(3)	(4)	(5)	(6)
·1	·1	·06	·12	·06	·04

Some of the English vermilions can be very much improved by washing with weak acid, as the following analysis shows :—

Ash before washing	·52	per cent.
,, after washing	·14	,,

All vermilions, including the best Chinese vermilion, blacken in sunlight, but are, I believe, stable pigments when exposed to the diffused light of a room or gallery.

Madder Carmine.—The madder lakes I have experimented on are of my own making, and are prepared by dyeing well washed alumina with artificial alizarine, and again thoroughly washing. I have prepared a purple, a ruby, and a rose madder. After a year's exposure, the purple has, possibly, lost a little, the ruby is unchanged, and the rose has very slightly faded, and become purpler in tint. They are all, practically, unaltered, but with a slight advantage in favour of the ruby madder.

The only other pigment open to question in this palette is French ultramarine. I have not made any experiments on this pigment, and shall therefore pass to Section II.

Naples Yellow.—I find no difficulty in preparing a real Naples yellow, that is a compound of oxide of lead and antimony of a fine colour, but have not exposed it for a sufficient time to test its durability.

Baryta Yellow, or Lemon Yellow.—Professor Church points out that lemon yellow is often a strontium, not a barium chromate, and that the barium chromate is much the most permanent of the two. I have, therefore, only experimented on the barium chromate, preparing it myself. It seems to me to lose slightly in brilliancy after twelvemonths' exposure. As

lead chrome and Prussian blue are known to be mutually destructive, I thought it as well to test a mixture of barium chrome and Prussian blue. I find that a bright green is produced, which is only slightly dulled by twelve months' exposure. Here and there the Prussian blue seems to have faded, causing the yellow to show up through it a little more, but they do not seem to have any injurious action on each other.

Purple madder I have already referred to; and I have not tested *Brown Madder* of my own making, for a longer period than six months; for that period it was not affected.

The two next pigments of doubtful stability are malachite and *Emerald Green*. Malachite is so little used that I have not experimented on it. I have described elsewhere the property which emerald green possesses of slightly dissolving in the linseed oil, and slowly diffusing through it after it is dry. It is, of course, fatal both to cadmium yellow and vermilion, turning them black. For this reason, I think it is better rejected, or, if used, only occasionally by itself, and far away from any cadmium yellow on the picture. I should advise the introduction of cobalt green into the palette. It is a durable and beautiful pigment.

Prussian Blue.—It is very difficult to try Prussian blue that has been properly washed. It is apt to contain as much as ·3 per cent. of free sulphuric acid, and often large quantities of potassium ferrocyanide. English makers are, in my experience, peculiarly careless; and I find it best to buy Prussian blue in Germany. It is troublesome to make. The blue I have obtained from there never contains more than ·01 per cent. of free acid, so that it is easily washed sufficiently. I have had some of a perfectly washed blue exposed for twelve months. I find it has faded somewhat, and become greener in tint. It must be remembered, however, that, in the dark, Prussian blue recovers; so that it should be stable in an ordinary room. I find it may be mixed with cobalt yellow with impunity. All the other pigments in this palette are of undoubted stability, and are above question.

In the course of these notes I have referred more than once to the effect of light on these pigments. My method of testing this was as follows:—I selected an attic window looking nearly due south, and I hung outside it a wooden frame, into which I could slide glass plates (half-plate size). After preparing, washing, and drying a pigment, I ground it in pure cold-pressed sun-refined linseed oil, and rubbed it out on two glass plates, getting the two patches of colour to look as nearly the same as possible. I put them both away to dry, and after they were dry I slipped one plate into the frame and put the other away into a plate box. In this way the plate outside was exposed to all the weather and sun for twelve months, from September to September. The pigments tested were:—

Twelve Months.

	Ruby madder....	Unchanged.
	Rose madder	More purple, very slightly faded.
	Purple madder ..	Perhaps very slightly faded.
	Cobalt yellow....	Unchanged.
(Barium)	Lemon yellow ..	A little duller.
(Chinese)	Vermillion	Black, or dirty brown.
	Prussian blue....	Faded, greener.

Six Months.

Brown madder ..	Unchanged.

These tests were of such exceptional severity, the exposure being outside, that I do not think any of these pigments should be removed from the selected palette, as they have practically (with the exception of vermilion) proved permanent. The reasons for not distrusting vermilion have been given elsewhere. As far then as my experiments have gone, I should only exclude emerald green from this palette, provided the pigments mentioned are properly prepared, and with such restrictions, as the avoidance of impure vermilion and of pale cadmium yellow, as at present manufactured. Of the other pigments, the most effected by exposure (after vermilion) is Prussian blue. Of the other blues of course cobalt blue is perfectly safe, but French ultramarine requires careful testing.

On the whole, however, this palette seems to me a very trustworthy one, and not at present open to much improvement. There are, however, various pigments excluded which are worthy of further trial, and may ultimately be re-introduced.

In all these experiments the pigments have been merely ground in pure oil. Different vehicles have a powerful influence on the durability of many pigments, and are worthy of special study. I have treated of this, however, at considerable length elsewhere, and need not repeat my experiments here.

The results may be briefly summed up as follows:—Linseed oil is permeable by moisture and gases, and consequently affords poor protection to pigments liable to be affected by moisture or certain gases.

The dissolving of resin in the oil, so as to make oil varnishes, such as copal oil varnish and amber oil varnish, has little or no effect in protecting the pigments, the moisture still penetrating.

Pure resin, when made into vehicles by solution in volatile liquids, and natural varnishes or balsams, such as Venice turpentine, *oleo de abezzo*, and others, do protect very effectively, excluding moisture and gases, and enhancing the durability of the pigment under adverse conditions.

(This probably accounts for the durability of most coloured lacquer work from Japan, when natural varnishes are used; and there is some historical evidence to show that balsam was largely used by both Flemish and Italian painters on vehicles.)

Certain pigments are soluble in linseed oil. For instance, verdigris is readily, emerald green slightly, soluble. Such pigments diffusing through the oil may be very destructive.

They are not soluble to the same extent, if at all, in resin. These results, though of little practical application at present, may, I hope, lead to the discovery of an improved medium, which will protect and isolate pigments ground in it, and so add to the durability of pictures.

DISCUSSION.

The CHAIRMAN said there were two aspects in which this question of the permanency of pigments might be considered—their interaction among themselves, combined with the action of sunlight upon them, and the exceedingly severe test to which they were subjected in the atmosphere of great cities, and of London in particular. The present state of London statues illustrated very forcibly the severity of our climate. The art of painting and of sculpture were very closely related, and in the past, Italian artists took enormous pains to get a composition into their bronze which should enable it to assume very delicate shades of colour. A little lead in the presence of the copper and tin alloy, known as bronze, enabled it to take a beautiful velvet coat. It was absolutely useless to try in the London atmosphere to make a composition of bronze that would turn any colour at all, except a black one. Take the equestrian statue of Lord Napier of Magdala, in Waterloo-place, opposite the Guards Memorial. Last year the layer of patina upon its surface was taking on a velvet coat; he watched it with the greatest interest all through. A fortnight ago a black-greenish tint had formed over both the soldier and the horse, and a little while after that very unsightly stains might be seen running over the whole statue, and now there was none of that delicate velvety brown tint which ought to be there. Indeed, the warrior seemed, by his very attitude, to recognise the fact, for he was turning, field-glass in hand, away from the Athenæum Club, as if perfectly conscious that in the present state of the London atmosphere he was beyond the aid of science, and that he would soon become sooty black like the unfortunate occupants of the adjoining pedestals. In the old days secrets were handed down from master to pupils; and was not that after all the reasonable way? Was it wise, in the present state of British art, to place in the hands of every votary the power of painting absolutely permanent pictures? Should there not be some kind of natural selection, which would enable only those who had established their right to enduring fame to use the excellent materials which Mr. Laurie had placed at their disposal. That, however, was not the question before them. They, as members of the Society of Arts, had to take care that the best materials were placed at the disposal of artists. Now he knew but little of art, but he had the good fortune to live a good deal among painters, and he was often, as a chemist, astonished at the utter recklessness with which they combined their colours, and at the general appearance, from the chemist's standpoint, of the palettes after a morning's work, and it was only by bringing home to artists little by little the criminal nature of such procedure, that they might hope to attain better results.

Mr. F. SHIELDS asked whether, in regard to the action of sulphuretted hydrogen in turning chrome yellow black, the lecturer had tried the effect of strong electric light in reproducing the yellow colour, after it had been turned black. He imagined, as the arc light was extremely strong in active rays, that, after the exposure of a few hours to a strong arc light, one could definitely decide whether it were likely that the colour would be restored by sunlight. In the case of white, the electric light restored the colour sooner than the sunlight; at least, such sunlight as they were able to get in the neighbourhood of London. His attention was first directed to this matter through some experiments tried by a friend in connection with phosphorescence.

Mr. LAURIE said the suggestion had not occurred to him, and it seemed a very good one. He always made his experiments twelve miles out of London, and at least 400 feet up the top of a hill, so that he got a little more light than could be got in London. He always, too, exposed the pigment not only to twelve months' sun, but also to all the weather.

Mr. WALTER FIELD said it would be useful if they could know where to get this balsam which was better to mix with the pigments than linseed oil.

Mr. LAURIE said it was balsam of larch which he employed. He did not think it could be got at

present. He obtained it from the Black Forest. It was not an article of commerce, though it might easily become one, because there was plenty of it. They might, perhaps, get it through a London drysalter; but, as he explained in a former lecture, though it was a point of great interest, it was of but little practical importance. One could not make a medium out of it which an artist would look at, because it was sticky, like Canada balsam. Then it was brittle, and apt to crack. Probably a mixture of linseed oil —more oil, with some pigments, and less with others —would represent the ideally perfect thing; but, if the balsam was introduced into pigments in large quantities, artists would not touch them. It was at present rather a point of theoretical interest, but it might lead to something better being found out.

Mr. WOLLASTON wished to ask whether it would not be possible to produce a vermilion, by the aid of hydrogen sulphide under pressure, so as to avoid the alkaline sulphates.

Mr. LAURIE said these Chinese vermilions were prepared by sublimating the sulphur and mercury together, and then one got the red sublimate on the top of the crucible; but he had not the faintest idea what would be produced by acting upon mercury and hydrogen sulphide under pressure.

The CHAIRMAN said it was well known alloys could be built up in that way by simple contact of metals under pressure, and there was every reason to think that sulphide might be formed if the pressure was sufficiently powerful.

In responding to the vote of thanks,

Mr. LAURIE, said he had hoped there would have been a little more discussion, though probably the paper did not lend itself to that. The remark they had heard as to the formation of hydrogen sulphide under pressure was interesting, at least from a theoretical point of view, because the black sulphide and the red sulphide were of the same composition—the difference being due to their different molecular states, and the fact that this sulphide is formed under pressure might have some bearing on that question. It would be very interesting to take mercurie sulphide prepared in this way, and test its durability against some others, the qualities of which in this respect are known. He had not described the actual receipts used in making the pigments, and they would perhaps hardly expect him to do so. He hoped the time would come when all good receipts for making such pigments would be published. All his receipts had been very carefully recorded, and he hoped the day would come when he might put them into print with the experiments. He wished artists would prepare their own pigments, and then they would not be afraid to publish their receipts. Meantime, receipts by which pigments could be made had a definite commercial value to him, as well as to anybody else. He was therefore in a half and half state—half the pure man of science who publishes everything, and half a commercial man who does not like to tell everything he knows. He hoped, however, soon to get his wings to fly into the pure scientific atmosphere, and to publish everything.

Mr. C. NAPIER HEMY, Churchfield, Falmouth, writes to the Secretary:—Thank you for your invitation to attend Mr. Laurie's lecture; I only wish it were possible. I read with the greatest interest his last paper in the *Journal*, and hope his paper of next Wednesday will find a place in its pages also. I have just been twice through Vibert's book, and am using his varnishes, but do not like doing so, as he does not tell us what they are made from. I was a pupil of Baron Leys, and there in Antwerp we used a medium called "zack," but Alma Tadema will be able to tell you about that. I had many talks with Baron Leys and certain French painters about pigments and mediums. I think if many painters would give us their personal experiences in a short form, it would be most helpful from one point of view at least. What artists want is something nice to paint with, so one takes Roberson's (pomatum) medium, and his picture goes yellow and dirty, and looks as if it had been buttered; another takes copal varnish, and it cracks; another, amber varnish, and the work gets horny or blooms; another, turpentine, and it goes dull; and so on. Now this question of mediums is far more important than that of pigments, and has far more to do, not only with the way a picture is painted, but how it stands. But the question of questions is, not the medium, nor the colours used, but the way they are put on to the canvas; not only the workmanship itself, but the quantity of medium and colour used. A glass of port may do a man good, but it does not follow that a whole bottle will do him more good. We use too much medium—too much oil or varnish, I mean; and instead of taking off the paint when we have gone wrong, we work over and over, and every coat of paint is a new danger. What a good thing it would be if every painter would write on the back of his picture the colours and mediums used in painting it, and where purchased; this would be some help. Though, as Leys said, it is, after all, the way a picture is painted, and not the colour used, which has to do with its durability.

Miscellaneous.

RUSSIAN TEXTILE INDUSTRIES.

The French Consul at St. Petersburg, in a recent report, says that manufacturing industries in Russia

have all experienced a considerable development during the last quarter of the century. Dating from the abolition of serfdom, the principal industries have made such an advance that they are now able to supply all the requirements of the home markets, and the importation of manufactured articles is becoming less every year. It is particularly the textile industries which have benefited by this movement, and these have now become one of the most important branches of the manufacturing interests of the country. The number of spinning mills and cloth factories, which, in 1885, amounted to 2,726, increased in 1889 to 2,979, while the production rose in value from 410 million roubles to 522 millions. In 1885 there were 336 establishments for the production of cotton goods, whose outturn was valued at 55 million roubles; in 1889 there were 534 factories, with a production valued at 68 millions. Silk goods realised 9 millions of roubles in the former year, and 12 millions in the latter. Woollen cloths were produced to the value of 42 million roubles in 1885, and 43 millions in 1889. Until within a very recent period, the cotton consumed in the Russian manufacturing establishments came from the United States of America, but the energetic measures adopted by the Russian Government with the view of developing the cultivation of the textile in Turkestan and the provinces of Central Asia have produced good results, and, for some time past, the cotton grown in these districts has taken the place of the foreign article. In 1888, 1,054,955 pouds (poud = 36 lbs. avoirdupois) of cotton were brought into Russia over the Asiatic frontier, and in 1889 1,459,808 pouds, valued at over 10,000,000 roubles. During the same period Egyptian cotton entered into competition with the American raw material. While the imports into Russia from Central Asia and Persia, of cotton, amounted to more than 1,500,000 pouds in 1889, this quantity was considerably increased in 1890; and from this it is deduced that the production of Russian cotton will be called upon in the future to play a very important part in the economy of the country. It is through the custom-house of Astrakhan, that this textile is introduced into Russia, where it is sent to Moscow or Warsaw, or direct to the spinning establishments. Foreign cotton enters through the ports of Reval, Liban, St. Petersburg, and Odessa, but it is principally to Moscow and Warsaw that the greater part of it is consigned, these two markets being the centres of the great cotton industry. The Governments of Vladimir and Moscow absorb half of these supplies, and the remainder is taken by Petrokovsk, St. Petersburg, and Esthonia. The largest number of spindles and looms are found in the province of Moscow, amounting respectively to 847,734 spindles, and 139,226 looms; St. Petersburg has 767,828 and 8,966; Vladimir, 554,148 and 3,606; and Petrokovsk, 505,715 and 10,127. The annual value of the production in Vladimir is estimated at 69 million roubles; in Moscow, 62 millions; in Peterovsk, 39 millions; and in St. Petersburg at 26 millions. It has been remarked that the large cotton manufacturing establishments of Moscow have recently opened shops for the retail sale of their goods in that city. This has been done with the double object of selling their goods for cash, and of showing the excellence of their goods, and of the favourable comparison they will bear with foreign products. The articles chiefly on sale are nankeens, satinettes, zephyrs, and cotton tissues used in upholstering.

Notes on Books.

HEINEMANN'S SCIENTIFIC HANDBOOKS: GEODESY. By J. Howard Gore. London: William Heinemann.

The author, in an opening chapter, deals with some primitive notions as to the form of the earth. The Hindoos held it to be hemispherical, and like a boat turned upside down resting upon the heads of four elephants, which stood on the back of an immense tortoise. Another view was, that the earth was formed like an egg, and floated in the ocean as in a basin. Gradually, some guesses, more or less true, as to the size of the earth were made; but it was not until the beginning of the 17th century that any accurate determinations were set out. It is to Willebrod Snell, the famous astronomer and mathematician, that the honour is due of initiating the system of triangulating from a known base. Mr. Gore gives, in his successive chapters, an account of the work done by Picard and Newton, of the continuation of spasmodic geodetic operations, until, in the 18th century, geodetic work was taken up in earnest, both in England and in France. A chapter is devoted to an account of the "Great Triangulation of India," set on foot by Lambton, and carried on by Everest, Waugh and other distinguished engineering officers. In the last chapter is given a sketch of the progress of geodetic work in the United States.

General Notes.

NORWAY AT THE CHICAGO EXHIBITION.—Information has been received from the Secretary of State for Foreign Affairs, by the Secretary of the Royal Commission, that the Storthing has voted £117,000 towards the expense of representing Norway at the Exhibition. The grant includes the sum of £2,775, which is to be expended in assisting handicraftsmen and other representatives of industry, &c., to visit the Exhibition. The Government has reserved the right of approving the designs for stands and cases in order that Norway may be worthily represented in regard to national art.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at Eight o'clock:—

March 16.—Tempest Anderson, M.D., "Iceland." Prof. Clement Le Neve Foster, D.Sc., will preside.

March 23.—Gilbert R. Redgrave, "Manufacture and Industrial Application of Flexible Tubing."

March 30.—Ewing Matheson, "Foreign Exchange."

Papers, the dates of reading of which are not yet fixed:—

"The Fisheries Department: its Position and spects." By J. W. Willis Bund.

The Congo State." By Captain V. Lovett meron, R.N., C.B.

"Colour Blindness." By Captain W. de W. Abney, C.B., F.R.S.

"Uses and Applications of Aluminium." By G. L. Addenbrooke.

"Egyptian Agriculture." By Professor Robert Wallace.

Foreign and Colonial Section.

Tuesdays, at Half-past Four or Eight o'clock; due notice of the hour will be given:—

March 15.—F. A. Pezet (Peruvian Consul General), "Peru: its Commerce and Resources." Clements R. Markham, C.B., F.R.S., will preside. 8 p.m.

April 5.—The Rev. John McLean, D.D. "Manitoba and the North-West Provinces of the Dominion."

April 26.—Sir Edward Braddon, K.C.M.G., "The Progress of Australasia." 8 p.m.

May 24.—Colonel Howard Vincent, C.B., M.P., "The Extension of Colonial Trade." 8 p.m.

Indian Section.

Thursday afternoons, at 4.30 p.m.:—

March 24.—G. H. M. Batten, formerly of the Bengal Civil Service, "The Opium Question." Sir John Strachey, G.C.S.I., C.I.E., will preside.

April 7.—Dr. J. Augustus Voelcker, "The Agricultural Needs of India."

April 28.—Sir William Wedderburn, Bart., "Reorganisation of Agricultural Credit in India."

May 19.—Jervoise Athelstane Baines, I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir Charles Bernard, K.C.S.I., will preside.

Applied Art Section.

Tuesday evenings, at Eight o'clock:—

March 29.—E. Roscoe Mullins, "The Decorative Uses of Sculpture." Alfred Gilbert, A.R.A., will preside.

April 12.—C. Purdon Clarke, C.I.E., "English Brocades and Figured Silks." The Lord Masham will preside.

May 17.—George J. Robinson, "Decorative Plaster Work" (II.). J. Hungerford Pollen will preside.

May 31.—William De Morgan, "Lustre Ware."

Cantor Lectures.

Monday evenings, at Eight o'clock:—

Prof. William Robinson, M.E., Assoc. M.Inst.C.E., "The Uses of Petroleum in Prime Movers." Four Lectures.

Lecture III.—March 14.—*Oil Gas.*—Gas generator and internal combustion engine *versus* steam-boiler and steam-engine.

Lecture IV.—March 21.—*Oil Fuel and Gaseous Fuel for Steam-boilers.*—Safe heavy oils available—Different methods of burning oils—Injector-burners—Evaporative power of oil fuel.—Advantages and disadvantages of liquid fuel on steamships—Transport and storage of petroleum—Other uses of petroleum for power purposes.

Bennett H. Brough, Assoc.R.S.M., F.G.S., "Mine Surveying." Three Lectures.

Lecture I.—March 28.—*Introductory.*—Nature of mineral deposits, and the modifications of the methods of surveying required in different mines—Accidents due to inaccurate surveying—Historical sketch—The oldest mine plan—The divining rod—The use of the magnetic needle in mapping deposits of iron ore.

Lecture II.—April 4.—*Surveying.*—The compass—Ancient forms of compass—Various forms of miner's dials and theodolites—Use of aluminium for mine-surveying instruments—Supply of light for reading the verniers underground.

Lecture III.—April 11.—*Levelling.*—The level and staff for underground use—Applications of levelling in mining operations—The Carrara marble railway—Aërial wire ropeways—Hydraulic mining ditches—The St. Gothard, Mont Cenis, and Croton aqueduct tunnels—The Ernst-August adit-level—Mapping bore-holes.

Dr. Percy Frankland, F.C.S., "Recent Contributions to the Chemistry and Bacteriology of the Fermentation Industries." Four Lectures.
May 2, 9, 16, 23.

MEETINGS FOR THE ENSUING WEEK.

Monday, March 14...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Prof. William Robinson, "The Uses of Petroleum in Prime Movers." (Lecture III.)

Royal Scottish Society of Arts, George-street, Edinburgh, 8 p.m. 1. Report of Committee on Mr. Laing's paper, "Distillations of Mineral Oils. 2. Mr. John Whitelaw, "A Miner's Safety Cage or Hoist, and Safety Hoists generally." 3. Mr. Thomas Gillespie, "An Improved Safety Cage for Pits, Hoists, Lifts, &c., for the prevention of loss of life or injury to plant from Ropes Breaking or from Over-winding."

Surveyors, 12, Great George-street, S.W., 8 p.m, Discussion on the "Small Agricultural Holdings Bill."

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Mr. G. H. Garrett, "Sierra Leone and the Interior, to the Upper Waters of the Niger."

Medical, 11, Chandos-street, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. C. Meymott Tidy, "Disinfectants, Gleanings from the Laboratory."

Tuesday, March 15...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Foreign and Colonial Section.) Mr. F. A. Pezet, "Peru: its Commerce and Resources."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Victor Horsley, "The Brain." (Lecture IX.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m.

Statistical, School of Mines, Jermyn-street, S.W., 7¾ p.m. Mr. John Glover, "Tonnage Statistics of the Decade 1880–90."

Pathological, 20, Hanover-square, W., 8½ p.m.

Zoological, 3, Hanover-square, W., 8½ p.m. 1. Dr. H. Gadow, "The Classification of Birds." 2. Mr. C. Brunner v. Waltenwyl and Prof. J. Redtenbacher, "The Orthoptera of the Island of St. Vincent, West Indies." 3. Mr. Oldfield Thomas, "Some Mammals from Mount Dulit, North Borneo."

Asiatic, 22, Albemarle-street, W., 4 p.m.

Wednesday, March 16...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Dr. Tempest Anderson, "Iceland."

Meteorological, 25, Great George-street, S.W., 7 p.m. Address by the President, Dr. C. Theodore Williams, "The Value of Meteorological Instruments in the selection of Health Resorts."

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. E. M. Nelson, "Virtual Images and Initial Magnifying Power." 2. Mr. H. L. Brevoost. "Obervations on the Brownian Movement." 3. Dr. A. C. Mercer, "Lantern Demonstration on Photomicrographs and Photomicrographic Apparatus."

Archælogical Association, 32, Sackville-street, W., 8 p.m.

Photographic Club, Anderton's Hotel, Fleet-street, E.C., 8 p.m. Mr. A. S. Newman, "Shutters."

Civil and Mechanical Engineers, Westminster Palace Hotel, S.W., 7 p.m. Mr. A. Fairlie Bruce, "Water Work Fittings."

Inventors' Institute, 27, Chancery-lane, W.C., 8 p.m.

Thursday, March 17...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. Allan P. Swan, "On the Vitality of the Spores of *Bacillus megaterium*." 2. Mr. Bertram Richardson, "Notes on the Zebras."

Chemical, Burlington-house, W., 8 p.m. 1. Prof. Dunstan, "The Conditions which determine Combination between the Cyanides of Zinc and Mercury and the Composition and Properties of the Resulting Double Salt." 2. Prof. Thorpe, "A Lecture Experiment, to Illustrate the Phenomena of Coal-Dust Explosions. 3. Dr. Armstrong and D[illegible] Kipping, "The Ketone Formed by the Action [illegible] Dehydrating Agents on Camphor." 4. Mr. [illegible] Pullinger, "Platinum Tetra-Chloride."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. A. A. Common, "The Chief Astronomical Laboratories of the World."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. W. P. Ker, "The Progress of Romance in the Middle Ages. (Lecture III.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m.

Historical, 20, Hanover-square, W., 8½ p.m. Prof. W. Cunningham, "The Perversion of Economic History."

Notices.

CANTOR LECTURES.

Prof. William Robinson, M.E., Assoc. M.Inst.C.E., delivered the third lecture of his course on "The Uses of Petroleum in Prime Movers," on Monday evening, 14th inst.

The lectures will be printed in the *Journal* during the summer recess.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1892 early in May next, and they therefore invite members of the Society to forward to the Secretary, on or before the 16th of April, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit for promoting Arts, Manufactures, or Commerce," and has been awarded as follows in previous years :—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S.

In 1865, to his Imperial Majesty, Napoleon III.

In 1866, to Michael Faraday, D.C.L., F.R.S.

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S.

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S.

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, &c.

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I.

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B.

In 1872, to Mr. (now Sir) Henry Bessemer, F.R.S.

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France.

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S.

In 1875, to Michel Chevalier.

In 1876, to Sir George B. Airy, K.C.B., F.R.S., late Astronomer Royal.

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France.

In 1878, to Sir Wm. G. Armstrong (now Lord Armstrong), C.B., D.C.L., F.R.S.

In 1879, to Sir William Thomson (now Lord Kelvin), LL.D., D.C.L., F.R.S.

In 1880, to James Prescott Joule, LL.D., D.C.L. F.R.S.

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin.

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S.

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.

In 1884, to Captain James Buchanan Eads.

In 1885, to Mr. (now Sir) Henry Doulton.

In 1886, to Samuel Cunliffe Lister (now Lord Masham).

In 1887, to Her Majesty the Queen.

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S.

In 1889, to John Percy, LL.D., F.R.S.

In 1890, to William Henry Perkin, F.R.S.

In 1891, to Sir Frederick Abel, K.C.B., D.C.L., D.Sc., F.R.S.

A full list of the services for which the medals were awarded was given in the last number of the *Journal*.

Chicago Exhibition, 1893.

MEETING OF THE ROYAL COMMISSION.

A meeting of the Royal Commission was held on Wednesday, 16th inst. Present:— The Attorney-General, M.P., Chairman of the Commission, in the chair; Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Sir Edward Birkbeck, Bart., M.P., Major.-Gen. Sir Owen Tudor Burne, K.C.S.I., C.I.E., Michael Carteighe, R. Brudenell Carter, F.R.C.S., B. Francis Cobb, Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., C.I.E., Professor James Dewar, M.A., F.R.S., Major-Gen. J. F. D. Donnelly. C.B., Sir James N. Douglass, F.R.S., Sir Henry Doulton, James Dredge, Francis Elgar, LL.D., Sir Douglas Galton, K.C.B, D.C.L., F.R.S., Alexander B. W. Kennedy, F.R.S., Charles Malcolm Kennedy, C.B., John Biddulph Martin, Professor William Chandler Roberts-Austen, C.B., F.R.S., Sir Owen Roberts, M.A., F.S.A., Sir Saul Samuel, K.C.M G., C.B., with Sir Henry Trueman Wood, M.A., as secretary.

ENGINEERING COMMITTEE.

The first meeting of the Committee on Engineering, Architecture, &c, was held on Monday, 14th inst. Present: Sir Frederick Bramwell, Bart., D.C.L., F.R.S., M.Inst.C.E. (Chairman of the Committee); William Anderson, D.C.L., F.R.S., M.Inst.C.E., Sir George H. Chubb, William Henry Corfield, M.A., M.D. Oxon., F.R.C.P., Sir James N. Douglass, F.R.S., M.Inst.C.E., Sir Douglas Galton, K.C.B., D.C.L., F.R.S., Charles Hawksley, M.Inst.C.E., William H. Massey, M.Inst.C.E., Reginald E. Middleton, Sir Robert Rawlinson, K.C.B., M.Inst.C.E., Colonel M. T. Sale, R.E., C.M.G., Captain Sir Henry W. Tyler, M.P., Professor W. Cawthorne Unwin, F.R.S., M.Inst.C.E., with Sir Henry Trueman Wood, Secretary to the Commission.

APPLICATIONS FOR SPACE IN THE BRITISH SECTION.

Intending exhibitors are reminded that applications for space must be made immediately, as the allotment of space will shortly commence. Most of the available space is now occupied, and no time should therefore be lost by manufacturers desiring to be represented.

All applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, and addressed to the Secretary, as above.

MEETING AT THE MANSION-HOUSE.

A meeting, promoted by the London Chamber of Commerce, was held on Friday afternoon, March 11th, at the Mansion-house, by kind permission of the Lord Mayor, to consider the British representation at the Chicago Exhibition.

There were present, among others :—The Lord Mayor in the chair; Sir Albert Rollit, M.P., Chairman of the London Chamber Commerce; Mr. Sheriff Foster. The following members of the Royal Commission: Sir George Birdwood, K.C.I.E., Major-General Sir Owen Tudor Burne, K.C.S.I., Mr. M. Carteighe, Mr. Francis Cobb, Sir Philip Cunliffe-Owen, K.C.B., Sir Douglas Galton, K.C.B., Professor Roberts - Austen, C.B., F.R.S., and Sir Owen Roberts, with Sir Henry Trueman Wood, Secretary; also Prof. Grylls Adams, F.R.S., Mr. R. K. Causton, M.P., Prof. George Forbes, F.R.S., Professor Hughes, F.R.S., Mr. Hyde Clarke, Sir James A. Youl, K.C.M.G., Mr. G. N. Hooper, Mr. Hunter Donaldson, Mr. Kenric B. Murray (Secretary of the London Chamber of Commerce), Mr. Ex-Sheriff Walter Harris, Colonel Fitzgerald, and Mr. R. S. McCormick (Representative in Great Britain of the Chicago Executive).

The Lord Mayor, in opening the proceedings said he had been asked to take the chair at this meeting, the object of which was, he thought, of the utmost national importance, viz., to see what could be done to further in any way the movement for securing that Great Britain should be properly represented at the forthcoming Chicago Exhibition. The history of Chicago was quite unparalleled, and he had been particularly struck with some of the facts relating to it, narrated in the handbook of regulations and general information with regard to the Exhibition which had been prepared. A century ago Chicago was a pathless wilderness; in 1832 the first business building was erected by Mr. F. W. Peck, the father of one of the most prominent and wealthiest citizen families of Chicago of to-day. In the year 1833 the population had increased to 350, and in the same year the United States Government commenced the harbour works, which had since assumed such large proportions. It was worth noting that when there were but 350 inhabitants, there were four churches and four taverns, and the inhabitants then were somewhat ambitious, for in the year 1837 they succeeded in raising their town to the dignity of a city. In that year, when the first census was taken, the population had increased to 4,170, and thenceforward its growth was very rapid to the year 1871, when the great fire occurred which destroyed more than three square miles of buildings, and rendered 98,500 persons homeless, the total loss being estimated at nearly £40,000,000 sterling. The modern Chicago dated from that conflagration, and ten years afterwards all visible traces of the devastation had disappeared, and the new era of construction had commenced. The Chicago of to-day covered an area of 180 square miles, with a population of over 1,200,000; there were 2,200 miles of street railways, and over 2,000 acres of public works. Thirty-five distinct railways had accommodation in the city, and it was claimed that those railroads, with their branches and immediate connections, amounted to half the railroad mileage in the United States. The river was crossed by 61 bridges. Its most important thoroughfare, State-street, running north and south, was eighteen miles in length, or only three miles less than the distance between London and Windsor. The number of houses added to Chicago last year would, if placed side by side, give a solid frontage of fifty-one miles;

they numbered 11,640 structures, and cost nearly £10,000,000 sterling. This was a wonderful record of growth since the fire, and it was now intended to hold there one of the largest, most universal, and probably one of the most successful Exhibitions of modern days. It was, therefore, of immense importance to England that she should be well represented there. They would probably all agree that trade competition was never greater than at the present moment, and having regard to the keen rivalry of the Americans, Germans, and other nations, it certainly behoved this country to be thoroughly well represented, so that it might go forth to the world, and to the millions who would visit this Exhibition, that we were not behind our neighbours, but that the England of old was the England of to-day. All European countries were giving their Commissions substantial grants, and although the Government of this country was not giving as large a grant as he should like to see, still it was supporting the Commission by a grant of £25,000. There was scarcely a movement of any importance which had not difficulties connected with it; and the great difficulty, in this instance, was the McKinley tariff. That certainly did not ease the way; but it, of course, only applied to America itself; and, inasmuch as the visitors would come from all parts of the globe, it was worth consideration, by the manufacturers of this country, whether it would not be well worth their while to send forward their exhibits, with a view to retaining and enlarging the number of their customers all over the globe. He could only urge that they would give this matter full consideration, so that we should not be behind others in placing our products in a favourable position.

Sir HENRY TRUEMAN WOOD said there were several members of the Royal Commission present who could speak with greater force on the general subject than he could, but there a few points with which his official work had, perhaps, rendered him more familiar, to which he was glad to have the opportunity of referring. First of all, he might say that a sufficient number of representative firms had sent in their names to the Royal Commission to make it quite certain that this country would be not inadequately represented, and further that, considering not only the exhibits from the mother country, but those coming from the various colonies and from India, the British Empire would be as well represented as it had ever been at any previous Exhibition. He would first mention the great difficulties in the way of exhibitors, and then show that they were not quite so great as might appear in the first instance. The Lord Mayor had alluded to the greatest in the McKinley tariff. The second was the great distance and consequent cost of exhibiting; and the third the special expenditure necessary for exhibitors in consequence of the whole expense not being defrayed by the Government grant. The McKinley tariff was, after all, not such a very large increase on the Customs' duties which had been maintained in America for many years; no doubt it was an increase, but it was not as if America had been a free trade country which had suddenly become protectionist. Then the tariff only affected half of the imports into the States, and with regard to one-half of the remainder, or one-fourth of the whole, it could have practically but small effect, because the goods therein comprised could not be made in the United States at all, and if they were to be consumed there they must be imported. It was by no means certain either that this tariff would be permanent. At the last congressional election the people declared very strongly against it, and it might consequently be very soon either abrogated or modified. It would be a matter of small importance that the tariff should be in existence during the Exhibition, if it came to an end immediately afterwards. The statistics, so far as they were available, showed a falling off in British exports during the past year, but it was almost as marked in the exports to other countries as to America. This went to show that a very small proportion of this loss was due to the tariff. The fact that the depression of trade now complained of was not due entirely to the tariff was shown by the example of two of the largest textile manufacturers, of whom one firm started a manufactory in the States, thinking that they could profitably manufacture their goods which they could not profitably export there; but they found it impossible; whilst the second firm, of equally high standing, having made inquiries, with the object of doing the same, found it would be impracticable, and abandoned the idea of setting up an American factory. As this point would be dealt with by Mr. McCormick, the representative of the American Executive, he would pass on to the other two points. First of all with regard to the distance; no doubt it involved a journey of 3,000 miles by water, and 1,000 miles by land, but this was minimised by the fact that the Royal Commission had obtained special and considerably diminished rates of freight, both by land and sea, and the American railways would also make a considerable reduction in their charges. No doubt the work of the Royal Commission would have been easier if they had had larger funds at their disposal. They could only say that they had this amount to administer, and would do so to the best of their ability, but the meeting should understand that it was an absolute necessity that additional charges should be made on the exhibitors if the country were to be adequately represented. All experience showed that £25,000, however economically expended, was not sufficient to defray the legitimate expenses of a section at a foreign Exhibition. Additional funds must come from somewhere, and there was no other source except the exhibitors —those who made special profits by exhibiting. The Commission administering a Foreign Section had not only to look after the interest of the ex-

hibitors—although that was their first and greatest duty—but also to see that the country was adequately represented in many departments for which funds were not forthcoming. He need only mention fine arts, and educational and scientific exhibits amongst others, all of which involved certain legitimate expenditure, which could not be met from the amount of the grant. In conclusion, he could endorse very strongly his Lordship's observations that English manufacturers must remember that the competition of other countries was becoming, day by day, more intense, that those other countries were fully awake to the importance of taking away our trade, and that it was our bounden duty to use all the means in our power to prevent them succeeding. The Americans themselves looked on this Exhibition as a magnificent opportunity for robbing us of our South American trade, and they were doing their best, quite legitimately from their point of view, to take it away from us, and we must do our best to prevent them. The Germans were vyeing with the Americans in the same direction. Other countries were doing the same; even our own colonies were more ready to see the advantage of exhibiting than our people at home; and it was our bounden duty to struggle to the utmost not to lose such a magnificent opportunity for advertising English industries in the presence of the great American public, and that vast crowd of exhibitors from all parts of the world who would be certain to congregate next year at Chicago.

Sir PHILIP CUNLIFFE-OWEN, K.C.B., K.C.M.G., C.I.E., said he ought to apologise for speaking at all, for he was an Exhibition man of the past, and they were considering an Exhibition of the future. Still there was some of the old spirit left in him yet. He did not like the idea of England being beaten by the Americans or any-one else. He was quite sure we had only to show what we could do, and we should carry the world with us. He hoped people would not be frightened at the McKinley tariff, which was held up as a bugbear. He believed that before the Exhibition was half over the tariff would be torn to pieces, because the American people would insist on having their goods at proper prices. They learned some of the real prices of goods on their visits to this country; but when they saw the prices marked on the goods in the Exhibition, they would insist on having the goods at the proper prices from the old country which had served them so well. They would know that goods sent from here were genuine and of sterling quality—which they could depend upon. He appealed to all gentlemen present to support the London Chamber of Commerce in making this Exhibition such a one as could be looked upon with pleasure and pride. He took it this was the final effort, and we were bound to show our relatives in America that we were still alive, and were not going to be superseded by any other nation. He knew how pushing foreigners were, and that they would push us out of the market if we would allow it, but if we did, it would be our own fault. He had had some experience of foreign nations, and knew what British manufacturers could do, and he was proud to say that England always came out first. He was certain that South Americans and others would much prefer going to English manufacturers where they would be certain the goods were what they were represented, rather than to the manufacturers of any other nation.

Mr. R. MCCORMICK said it gave him great pleasure, immediately after his arrival from Chicago, to be able to report progress at the seat of war—he might call it—the war of friendly commercial rivalry, in which he hoped Great Britain would take a leading part, such a part, that not only Old England, but New England, would have reason to be proud. The buildings were progressing satisfactorily. It was said that Americans treated women with the greatest possible consideration, and as evidence of that, he might say that the women's building was the first to be completed, and only now required to receive the decorations, which were sure to be successful. Reference had been made to the effect of the McKinley tariff on the trade with America; most present knew probably, though they might have forgotten it, that the Americans were far away England's best customers, for in the first nine months of last year, during the operations of the McKinley tariff, there were over £21,000,000 sterling in manufactured articles sent to America, whilst Germany, the next best customer, took about £14,000,000. That was a trade which England could well afford to cultivate. There was one important fact which would make it necessary for a long time for America to take a large amount of manufactured goods from England. There was an enormous work to do in the construction of new lines of railway, the making of new canals, and the development of internal commerce, which would take a large number of working men, to clothe whom they must purchase from abroad. England had always furnished America with large quantities of woollen and cotton goods. Some idea of the amount of internal commerce might be drawn from these figures. In 1890 the tonnage of vessels proceeding through the Detroit River was 21,000,000 tons—more than three and a half times that passing through the Suez Canal. The tonnage of vessels arriving at and departing from Chicago was 8,000,000.* These figures gave some idea what the consumption of foreign goods must be. Then it must be remembered that America had to send to Europe a large proportion of bread stuffs and meat products, and as long as that continued she must largely take manufactured articles in return. It would be long before she would be able to consume the whole of these produts herself, and during that time England must be a large exporter

* The tonnage of vessels arriving at and departing from Liverpool was 11,000,000 in round numbers.

to the States. All these exports and imports too were carried under the British flag in British bottoms. In that trade America was not now a competitor, though he hoped she soon would be. They intended to leave no stone unturned to gain what they thought their share of the trade with South America. She was a neighbour, and they proposed to enter into a friendly contest with England to get that trade if they could; they would try to undersell the old country and would be able to supply quite as good a quality of goods. He might also say that what America knew about tariffs she had learnt from England. It was only a few years ago that England abolished her tariff, and that was when she felt herself strong enough to throw down the gauntlet to the world. It was like a merchant who had accumulated a large amount of capital and then said, "I can undersell you, no matter what other advantages you have." America had never gone so far as England had in protecting her woollen trade. She had never placed an embargo on the export of cotton, which might have been done if there was anything hostile in the passage of a Tariff Act; but had allowed England to take American cotton, manufacture it, and send it back again, paying the freight on it both ways to English carriers. He hoped that, when he returned to Chicago, at the opening of the Exhibition, he should be able to feel proud, not only of the exhibits of his own country, but equally proud of those furnished by Great Britain, and to congratulate his friends of the Royal Commission on the good work he was sure they would accomplish.

Sir DOUGLAS GALTON, K.C.B., said he attended on behalf of the Council of the Society of Arts, who had undertaken, at the request of the Government, to act as a Royal Commission for promoting this Exhibition, and he hoped that, with the assistance of the Lord Mayor and the London Chamber of Commerce, they would be able to do so effectively. The a[illegible]ges of exhibiting in Chicago had been so full[illegible]ward by previous speakers, that he could r[illegible]ch on that point, but he might say that [illegible]he advantage of visiting America on ma[illegible]nd was present at the Philadelphia E[illegible]which the American manufacturers r[illegible]glish competitors very close indeed, esp[illegible] machinery. He thought, therefore, it wou[illegible]e a great misfortune for this country if her mac[illegible]nists did not take part in this Exhibition. He believed they would have an opportunity there, which was not allowed at Philadelphia, of stating on the exhibits what the price would be apart from the duty. If this were allowed, it could hardly fail to strike a serious blow at the McKinley tariff. He trusted, therefore, that British manufacturers would make a good appearance at Chicago in competition with their American cousins.

Sir OWEN TUDOR BURNE, K.C.S.I., C.I.E., said he could really add nothing to what had been so ably stated by the Lord Mayor and others as to the forthcoming Chicago Exposition, but he, as one of the Royal Commissioners, hoped all present would take to heart what had been said, and that there would be a good British exhibit. They all knew that the colonies were making great efforts to take a prominent part in the Exposition, and he had reason to believe that India also would come out strongly on this occasion; he hoped, therefore, the mother country would not be behindhand. The Royal Commission was very anxious to give information or assistance in any possible way, through its secretary, Sir Henry Trueman Wood, who had already taken so much trouble in the matter. He enjoined all to put their shoulders to the wheel, so as not to be left behindhand by the Colonies and India, but rather to bring out Old England in the position she ought to occupy, especially as this might be her last struggle to maintain her pre-emience in the commerce of the world.

Sir A. K. ROLLIT, M.P., then moved:—"That the best thanks of the Chamber of Commerce and of this meeting be given to the Right Hon. the Lord Mayor for presiding, and for permitting this meeting to be held in the Mansion-house." When the Chamber of Commerce, doing as it thought its duty to the commerce of London, asked the Lord Mayor to allow the meeting to take place there, the proposal was readily entertained, and every possible facility given; and he might mention as showing how busy the life of a Lord Mayor was that that was the second time that day he had proposed a vote of thanks to him in that room. That morning his Lordship had received the Municipal Corporations, and that afternoon the representatives of commerce; and he did so in the same admirable way as that in which he took part in all movements of a good character. They owed him very much for his introductory speech. John Bright once said that not a boy in a day school could take a map and put his finger on Chicago. The Lord Mayor had certainly shown himself possessed of a great deal of knowledge about it; and that information was now shared by all. There was no doubt that this movement was for the welfare of the country, and was brought forward on that broad basis, that competition had to be met. Without following all that had been said by Sir Philip Cunliffe-Owen, he might remind them of what an equally great man—Voltaire—had said, that England rules the waves, France the land, and Germany the clouds. England still ruled the sea, and hoped to continue to rule it commercially, notwithstanding the efforts of their American friends. The ruling of the land might be a debatable question, but Germany certainly did not merely rule the clouds. She had come down from the clouds, and we had to meet her competition on the land. But Germany had the wisdom, a century before we began to learn it, to

see the necessity of education. It was to that she owed her present position, and we should take care that our people had similar advantages, and that they were placed abreast of the times in getting that knowledge which was the very condition of profit, a knowledge of saving, and of the methods of lessening the costs of production. That could be done no better than at these Exhibitions, and it would be a great lesson to our countrymen if they took part in it. There was a great deal of justifiable feeling about the McKinley tariff, but there was a hope that it would not be permanent. One of the speakers had bidden them go to their relations, and it could not be supposed that those relations would close the door in their faces. It would have to be opened. He never met an American woman who did not hate the McKinley tariff. They must have their costumes imported, and they hated having to pay the duty, so that in the days when women got votes there would be a powerful influence brought to bear on this question, and he trusted that would be an indication of better times and improved commercial relations. Already some concessions had been made which should be appreciated. He had reason to believe that the real true price at which articles could be obtained in England, irrespective of duty, would be allowed to be marked upon them, which would be certainly a benefit to the exhibitors of this country. It would prevent any misapprehension, and might illustrate certain economical principles for the benefit of America. The Chamber of Commerce were taking steps to establish an Intelligence Department in the grounds of the Exhibition, so that the full benefit of English enterprise in that direction might be reaped by those who took the trouble and incurred some expense in exhibiting. He had been asked to mention that the official date for applications to exhibit had passed, but there was still some space left, although it was rapidly being occnpied, so that early application was necessary.

Mr. Sheriff FOSTER, in seconding the motion, said they were all under a debt of gratitude to the Lord Mayor for the useful information he had contributed. They had been told that the McKinley tariff would be a great obstacle to the success of this Exhibition, but he ventured to think that its importance had been to a great extent removed. Even if it were to continue, this being a World's Fair, the exhibitors might hope to find customers from all the world, even if the United States were partially closed to them. Mr. McCormick had told them that the United States intended to try for the South American trade, and that alone was worth struggling for. But they might hope that the citizens of the United States would not be so foolish as to continue to allow themselves to be taxed in this way. He was present at Philadelphia, in 1876; and even his inexperienced eye was attracted by the Engineering Section, to which Sir Douglas Galton had referred; nd it was quite evident that English engineers would have to do their best in order to maintain their position.

The vote of thanks having been carried by acclamation,

The LORD MAYOR briefly responded, and the proceedings terminated.

Proceedings of the Society.

FOREIGN & COLONIAL SECTION.

Tuesday, March 15, 1892: CLEMENTS R. MARKHAM, C.B., F.R.S., in the chair. The paper read was "Peru: its Commerce and Resources," by F. A. PEZET.

The paper and discussion will be printed in next week's *Journal.*

FOURTEENTH ORDINARY MEETING.

Wednesday, March 16, 1892; Professor CLEMENT LE NEVE FOSTER, D.Sc., in the chair.

The following candidates were proposed fo[illegible] election as members of the Society:—

Corderoy, George, 19, Queen Anne's-gate, S.W.
Cowper, Joseph, Penrith.
Crossley, Arthur W., Bentcliffe-house, Accrington.
Lloyd, Edmund H., Selhurst, 8, The Avenue, Ealing, W.
Ravershaw, Henry Willock, 32, Albany-road, Ealing Dene, W.
Rotch, A. Lawrence, Readville, Massachusetts, U.S.A.
Toop, Robert, Trent-villa, [illegible]on-road, Bournemouth.
Walker, Theodore, Glen-[illegible]eicester.
Wates, Edward A., Lon[illegible]an, India.

The following ca[illegible]e balloted for and duly elected m[illegible] Society:—

Gough, Kedgwin E. K., [illegible]n-road, Brixton, S.W., and Board of Trade, [illegible].
Grant, William, University C[illegible]ege, Gower-street, W.C.
Kapp, Gisbert, 31, Parliament-street, S.W.
Legard, Colonel James D., 13, The Cliff, Scarborough.
MacLean, Robert Black, Woodville, Burghill-road, Sydenham, S.E.
Scorgie, James, Poona-villa, King's-gate, Aberdeen.
Scott, Ernest, 3, Investment-buildings, 67, Lord-street, Liverpool.

The paper read was—

ICELAND.

By Tempest Anderson, M.D., B.Sc.

The author visited Iceland in the summer of 1890, with the especial object of examining and photographing the volcanic phenomena with which the country abounds. When, therefore, he was asked by your Secretary to exhibit his photographs before your Society, he proposed, as a title, "The Icelandic Volcanoes;" but on its being pointed out that the Society of Arts does not deal with questions of abstract science, but only with its applications to the useful arts, and that volcanoes are chiefly destructive in their effects on man and his works, he agreed, with some misgivings, to say more on the material and social condition of Iceland and its inhabitants, and less on the main objects of his visit to that country.

Iceland is an island about the size of Ireland, situated just outside the Arctic circle. The inhabited, or habitable, portion is confined to a narrow belt round the shore, the centre portion being occupied by volcanic mountains, lava extensive deserts, sandy [illegible]s, and snow mountains mostly flat-[illegible]ed, called "Jokuls." The interior is [illegible]ersed by a few desert tracks, seldom [illegible]sed, and becoming less so since the establishment of a regular service of steamers round the north coast. The north coast is much broken up into promontories and fjords, or deep bays, at the ends of which most of the villages—they scarcely deserve the name of towns—are situated. The south coast, on the contrary, does not boast a single harbour where a steamer can lie in safety, between Reykjavik and Hafnafjord on the west, and Berufjord on the east, for, though it is true that the small trading station of Eyra Bakki is situated here, and small sailing vessels find some shelter from the Atlantic swell behind a reef of rocks, the entrance is narrow and dangerous for any ordinary craft in which a landsman would like to trust himself. Add to this, that many large rivers, quite disproportionate to the size of the island, come from the desert interior and here flow into the sea; that they are mostly broad, swift, and icy cold, and often with quicksands in their bottoms; and we see at once the reason that this part of the island is seldom visited by travellers, and that the inhabitants enjoy fewer of the necessities, to say nothing of the luxuries, of life than in other parts. Yet in this part are situated the great volcanos of Kotlugiâ and Skapta Jokul, which it was the author's object to explore on his visit to the island in 1890.

Iceland can be reached in about four or five days by steamer from Leith, at intervals of about a fortnight or a month. The Danish mail steamers run about once a month, and at any rate one of them, the *Laura*, has the reputation of being an excellent boat. They call at the Faroe Islands, thereby making the passage extend to seven days instead of five, and are sometimes behind time, but can be depended on eventually to arrive at their destination. The Scotch boats run nominally once a fortnight during the season, but really only if sufficient cargo offers, and hence cannot be depended on for a return passage, as the author knows to his cost. Two of them have been lost during the last few years.

Arriving at Reykjavik, we find ourselves in the capital of Iceland, a straggling village or small town of 2,500 inhabitants. The chief buildings are the Governor's house, a plain whitewashed building apparently of about a dozen small rooms, a church or cathedral, also whitewashed, capable of holding probably 400 people, and the Parliament-house, a building of very moderate dimensions, yet accommodating a free library on the ground floor, the Parliament chamber on the first floor, and the national museum in the attics. The Latin school, and one or two elementary schools, complete the sum of the public buildings, except the gaol, which has twelve cells generally empty. Long may it continue so.

There are several stores where may be bought a motley assortment of goods from a needle to a chain cable, and from paraffin to tinned meats, and Manchester goods. The houses are nearly all of wood or galvanized iron, for though there is plenty of stone and materials for making the best cement in the island, there is no fuel to burn it or lime. Dried fish is the staple commodity of the place. It can be seen spread out to dry on the rocks, the beach, and the streets, whenever the weather is favourable.

The climate is not as severe as might be expected from the latitude—just outside the Arctic circle. The island being situated in the Atlantic in the western prolongation of the Gulf stream, does not suffer from such extreme cold as the adjacent coast of Greenland. As far as I could gather, the windward side of the island is generally covered with clouds and mist, owing to the moisture being condensed from the comparatively warm sea air by contact

with the cold mountains of the interior, while the air, thus deprived of its moisture, passes forwards, and the lee side is comparatively dry and clear. As the wind was south-west during the greater part of June and July, 1890, the author, in the south-west of the island, had ample opportunities of verifying the truth of this statement. It is most tantalising to ride for days together in a cold drizzle under the cloud-cap, while in the distance, to windward, it constantly looks as if the weather were clearing up, the fact really being that the air at that distance has not yet felt the influence of the cold land, and its moisture is still in solution.

[Photographs illustrating these appearances were shown on the screen.]

The northern part of the island has the reputation of being drier than the south, a fact amply accounted for by the prevalence of the south-west winds. On the other hand, to some extent every spring, but to a serious extent at intervals of a few years, large masses of polar ice occasionally drift down on the north coast, and that district then comes in for its share of cold, wet, and mist. In a bad "ice year" the hay—the only harvest—does not ripen; the sheep and ponies die in large numbers, or have to be killed, and the natives are threatened with starvation.

The first requisite to a traveller in Iceland is a guide and ponies. As to the former Thorda Zoega had been written to in advance, and he proved a very obliging and trustworthy man. The Icelandic ponies are a similar breed to the Shetland ponies. They are very hardy little beasts, never taste corn, live on fresh grass in the summer, and a little hay and a few dried codfish heads in the winter, and as even these are often scarce they are often very weak and in poor condition in the spring, a reason against visiting the island before June or July. It is usual to have two ponies to each load, animate, or inanimate, one being loaded in the morning the other in the afternoon. The spare ponies run along unloaded, and in this way they will travel long distances of 40 or 50 miles a day for days in succession, provided the pace is varied, first walking, then trotting a few hundred yards, then a short gallop, then walking again, with occasional rests. They run well in company. Out of fifteen or twenty one or two will soon be recognised as the leaders, and the rest will follow these, but no amount of whipping will persuade them to go even a short distance separately, a fact which the traveller soon finds very inconvenient if his pony does not happen to be a leader, and he is yet anxious to deviate occasionally to examine objects of interest off the track. This inability to run except in company has gained the Icelandic ponies a character for stupidity in this country, where they are seldom used except in the coal mines. For this purpose several cargoes of 300 or 400 each are exported yearly to Newcastle. The Icelanders do not understand breeding ponies, and hence make no effort at selecting the best to breed from, a fact which much diminishes their possible value as an article of trade.

The traveller will be astonished at the number of ponies necessary to transport himself, his guides, and the most moderate amount of luggage. Each pony will only carry a pair of wood boxes, each as large as a small Gladstone bag, and where, besides the personal luggage, photographic plates, provisions, and a tent have to be carried, this requires at least three pack horses, or six including the relays. Two travellers and the guide, at two a-piece, makes six more, or twelve in all; and twelve horses require two men or boys to prevent them straying at night, each of whom require two horses, making sixteen, or, with a spar[illegible] horse, seventeen, which was the number ta[illegible] It is needless to say that this renders travel[illegible] in Iceland more expensive than in any ot[illegible] European country.

It is interesting to note that on returning to York with the baggage as above, one of the saddles, and a large collection of stones which had been accumulated in three batches at Reykjavik, the writer naturally was going to take two one-horse cabs, but the first cabman volunteered that he could take it all, including the two travellers, very well on one; a proof, if one were needed, of the advantage effected by the use of wheeled conveyances and good roads.

The most useful provisions to take are tinned meats, biscuits, a few raisins, and tea, or, still better, chocolate. Coffee can always be obtained, even at the worst farms, and is generally excellent, but owing to the want of fuel, the traveller arriving after riding all day in the wet, will often have to wait two hours before he can get anything to eat or drink. Hence it is advisable to take some form of portable apparatus capable of quickly boiling a pint or two of water, and, if posible, it should burn paraffin, which can be got in most places.

Except in Reykjavik, and possibly one or two other towns, there are no hotels or inns of any kind, and the traveller must either live in

his tent or lodge at the farmhouses, where it is only fair to say he will almost universally be received most hospitably and provided with the best, such as it is, that the place affords.

The Icelander is under great disadvantages in the construction of his house. If he has lime he has no fuel to burn it, he has no wood except that cast on the shore by the Gulf Stream, which provides him with a few worm-eaten pine trees and a very occasional balk of mahogany which has broken astray from a raft in some South American river, or been washed off a ship's deck in a storm. He has no straw for thatch, no slates or tiles, or fuel to burn them, no glass, except that carried on horse-back for great distances over vile bridle roads and well nigh impassable rivers. The house is therefore built of rough blocks of lava, bedded in turf, to form walls about six feet thick, and banked up with earth on three sides. The roof boasts a few wooden rafters, but is mainly composed of birch bark covered with a thick layer of earth and sods. The best grass of the farm is that cut from its roof. The front of the house is usually built in gables of stone and turf at the bottom and wood above, with a few small windows. These sometimes open, often [illegible] in which case there will occasionally be one or two holes in the frames about an inch in diameter, closed by plugs which can be removed when it is desired to admit a little air.

The Icelander has no coal or wood, and very little peat for fuel, and must content himself with a little turf or dried horse dung. If he uses turf, it is years before it grows again; and often, in the meantime, the wind gets hold of the volcanic sand so laid bare, and spreads it over, and so ruins the adjacent pastures. In the result, he must build a house with no fireplace except in the kitchen, and with rooms so small that the inmates keep each other warm by overcrowding. The chief room is used as the sitting-room by day and the bed-room by night, and is occupied by the farmer, his wife and family, the servants, male and female, in all often more than 20 or 30 persons. It is provided with no fire or stove, but with beds all round, sometimes two stories high, like the berths of a ship. The lower row serve as seats in the day. There are often, perhaps generally, no chairs, except one or two in the guest-room, which is kept for strangers, and only used by the family on ceremonial occasions.

What wonder that people, living in such conditions, in a vile, damp, cold climate, suffer from chronic bronchitis and rheumatism; that leprosy is far from uncommon, and that tape-worm, echinococcus cysts, and other parasites abound. The guest-room is generally about 10 feet by 7 feet; sometimes a little larger. It is lined with wood, and has several wood pegs, on which hang the spare garments of the family; several chests, which contain family treasures, and serve as seats; sometimes a chair or two, generally, a small table. The bed is often built into a recess in the wall. If the traveller is induced, by stress of weather, to attempt to use it, he often finds it already occupied, and is often kept awake by the constant coughing in the next room; for every Icelander has a cough.

The inhabitants, though of the same stock as the Norwegians and the Yorkshiremen of England, both tall races, are mostly stunted by generations of hardship. Like most inhabitants of out-of-the-way places, they are almost without exception, hospitable, obliging, and honest in their dealings with strangers. The men wear short, double-breasted coats of home-spun cloth, generally dark coloured, and when travelling, long boots, reaching well up above the knees. These are for fording the numerous rivers. At other times, they wear a sort of moccassin of untanned sheepskin. It is made in one piece, the corners being brought up, and fastened in some way over the instep. The women wear, usually, little distinctive of their nationality, except a cap with a tassel, said to be a survival of the old Phrygian cap. Some of them still possess jackets and skirts, ornamented with silver embroidery, and belts of filigree silver of fine workmanship. These are now getting scarce, but specimens may be seen in the Museum at Reykjavik.

With all the above described material difficulties to contend with, it is not surprising that many of the Icelanders have emigrated to America, but I was confidently assured that many of these emigrants would be glad to be back. The Icelandic farmer is not accustomed to hard manual work. His house was built generations ago, and receives, I will not say requires, little repairs. He has no ploughing to do, no harvesting except the little hay, he seldom walks about his farm, but almost always rides, and thus, though perhaps often short of food, contrives to exist. When he sells his belongings and emigrates, he realises, I was told, perhaps £50, most of which is spent by the time he arrives at his destination, and he then has no horse to ride, no ancestral house, and no means of living except by manual work, in which he has to compete with

English and Irish labourers accustomed to do half as much more in the same time, though possibly not for such long hours.

In the more remote parts, such as the Skaptadalr, many articles of bone and stone are still in use, which, in more accessible districts, have been replaced by metal or earthenware. A photograph exhibited shows a wheelbarrow with a stone wheel, a steelyard with a stone weight, a hammer with a stone head, and a net with bone sinkers. At the same farm a quern, or stone hand mill, was in use, also horn stirrups, and harness fastenings of bone instead of metal buckles, to say nothing of bone pins and rude bone dice. At a neighbouring farm was a basin formed of the cup joint of a basalt pillar. Truly we still have a survival of the stone age. Less remote than this is the meeting place of the County Council of the district, consisting of a spacious cave in the lava. It would be difficult to find anything more appropriate to such a primitive land.

The roads, such as they are, are merely bridle tracks. Where they traverse stony moors and lava streams, they are mended by taking off the largest stones, leaving the smaller to tread down; where they cross bogs they are occasionally carried on artificial embankments. Bridges are almost unknown. In the few cases where new roads have been made, they have evidently been laid out by unskilled persons, and the work has often been begun in the middle; then, before the road has been finished, the plan has been changed, and the whole abandoned. I saw several large pieces of road out in the wilds leading nowhere, and which will never be used. It is only fair to say, however, that near Reykjavik there is about twenty miles of new road beautifully engineered by men who have recently returned from learning road-making in Norway. Even in these roads, however, there are gaps left unmade at intervals. This, I was told (let us hope falsely), is to prevent people spoiling them by using wheeled carriages or carts on them.

The numerous hot springs constitute one of the chief wonders of Iceland. They are very numerous, and as various in their volume as in the composition of their waters and the products deposited from them. The great Geyser, which has been so often described, spouts its mighty volume of water, only slightly charged with silica, and deposits a silicious sinter called geyserite; and several other springs, such as at Reykjanæs, deposit similar formations; others are so charged with ferruginous and sulphurous mud, that they appear like boiling cauldrons of red and blue paint. Some of the Reykjanæs springs, and many of those at Krisuvik, are of this kind, as are the more celebrated mud geysers of Krabla, in the north of the island.

At Krisuvik, and some other places, besides but connected with the springs, are fumaroles, from which some sulphurous vapour and steam escapes. This has given rise to deposits, more or less extensive, of sulphurous earth or mud, on the top of which a crust forms on which it is possible to walk; care is, however, necessary, for if the traveller should happen to go through the crust, he will be precipitated into a mass of boiling sulphurous mud. It has been proposed to work these deposits for shipment to England, and a company was formed, which came to an untimely end. We visited the house built for the manager at the springs; it was built of galvanised iron. Could any one have conceived a material less likely to resist sulphur fumes? There were many difficulties which operated to prevent success. The natural idea would have been to burn the crude sulphur in *calcaroni*, or kilns, like those used in Sicil[illegible] The heat produced by the burning of [illegible] of the sulphur melts the remainder, and it [illegible] out in a refined state into moulds. Bu[illegible] Sicily the deposit is dry—here it was liqu[illegible] mud; there was no means of drying it. Krisuvik is near the sea, and this was conspicuously marked on the map published at the time; but the coast is rocky, and there is no landing-place. In reality, the sulphur had to be carried on ponies for many miles over the mountains to Hafnafjordr. We were told that about seventy horses died one year, and the attempt was then abandoned. No wonder the venture was unprofitable to the shareholders.

The rivers of Iceland are large, and out of all proportion to the island, and are especially large and dangerous in the southern part, as it is here that most of the great rivers draining the desert interior of the island, and especially the glacier streams proceeding from the Myrdals, Skaptar, and Vatna Jokuls discharge themselves into the sea. They constitute, in this district at any rate, a most serious hindrance, and occasionally a positive danger to the traveller. Most of the worst are broad and swift, rather than very deep, a common size being a quarter of a mile or more wide, the depth in the fordable parts perhaps four feet, and the rapidity sufficient to make the icy cold water surge and foam up against the

traveller's saddle and water boots. It is no wonder that a stream of these dimensions, flowing over a sandy and gravelly bottom, constantly shifts its course, and that quicksands are common. A place may be safely fordable to-day, and deep water next week. Hence the necessity of always taking a local guide from the nearest farm. Where the river comes from a lake, the water will be pretty clear, so that the bottom is partly visible; but if from a glacier, it will be loaded with mud, which prevents a view of the bottom, and this, with its icy coldness, adds greatly to the difficulty and danger of the crossing. Deaths occur not infrequently from horse and rider being carried away. Sometimes a river spreads itself out into many parallel arms, and the guide in search of a ford seeks by preference such a part. If the river is not fordable at present he must seek a ferry at a narrow part where the banks are good. This is always a tedious undertaking. First the ferryman must be found, which is sometimes difficult even if he lives on the near side of the river, but the difficulty is much worse if both he and the boat are on the opposite. Then all the horses are unsaddled, and the saddles, pack boxes, and gear are put into the rickety boat, and the horses, with much shouting and cracking of whips, are driven unwillingly into the stream. As soon as they are well swimming, and too far out to turn back, the travellers and guides hurry across in the boat as quickly as possible. By the time they are across the horses have all landed, and, feeling cold, have started off at a canter. A guide runs after them, and with some trouble catches one, which he mounts, and pursues the others, and eventually drives them all back to the ferry. Then the whole cavalcade has to be resaddled, and the packs adjusted, so that, before the caravan is fairly on its way again, at least an hour, but often more, has been wasted. What wonder that the guide always prefers to ford if possible.

The main object of our visit was to examine the great volcanos of Kotugiá and the Skaptá Jokul, the former of which appears not to have been visited this century, while the crater of the latter had, we were assured, never been reached since its formation in 1783.

The crater of Kotlugiá is a vast fissure situated high up among the glaciers of the Myrdals Jokul, and is now so filled with snow and ice that our distant view of it did not promise much from a nearer inspection. Moreover, the weather being abominable, and the snow in bad condition, we were reluctantly compelled to abandon the attempt. One peculiarity of the eruptions arises from its position under a glacier or snowfield, viz,, that when the incandescent gases and lava escape, the snow and ice are suddenly melted, and a vast outpouring takes place of mingled boiling water, ice, volcanic mud, pumice stones, and ashes. This rushes with great velocity to the sea, devastating everything. We rode across a plain about twenty miles wide, which marks the track. The last eruption took place in 1866. Scarcely a blade of any kind of vegetation has yet begun to appear on all this vast area. Certainly the volcano deserves its name of Kotugiá, the Kettle crater.

The second main object of our journey was to explore the lava fields of the Skaptá Jokul, mentioned in all the books on vulcanology as being among the largest known. The great eruption of this volcano in 1783 is well described by Lord Dufferin in his "Letters from High Latitudes," and especially by Henderson, a missionary who visited the island in 1814, when the facts were fresh in living memory. Two great streams of lava issued from the desert interior of the island, one descending the valley of the Skaptá river, and another, that of the Hervisflot, the first being about fifty miles long, and the latter perhaps forty. Both appear to have issued from the same great fissure, on which a line of craters has been thrown up. We determined to endeavour to reach the craters by the former valley. We slept at the last farm in the valley, and were fortunate in obtaining the old farmer as guide. He at once told us that, though he had taken several parties of travellers far up the course of the lava, none had ever reached the crater; but he was quite willing to make the attempt. We therefore started next morning, keeping at first some distance from and then close alongside the lava. At last we found it necessary, in order to get to a set of cinder heaps which promised a passable road, to cross the main stream, and had some difficulty in getting our clever little nags across; but perseverance prevailed, and going further on, we encamped in the evening at the last patch of grass at the edge of the desert. Next morning, after a hard, frosty night, the weather proved good, in fact, the only good day for many days, and by riding as far as possible into the desert, and then leaving the horses and going forward on foot, the craters, the objects of such a long journey, were at last reached. They extend in a line for several

miles along a great fissure, which is still, in many places, clearly visible. At the lower end are two or three dwarf craters, then the two or three main orifices, from which most of the lava has poured out in billows of fire, now solid and black, it is true, but retaining their shape perfectly; and, further on, several others from which the gases and steam evidently chiefly escaped.

The higher craters, from which the steam and vapours escaped, are roundish or oval; and the fissure can still be seen along their bottoms in places, of a width of several feet. Traces of it are also visible going under the heaps of scoriæ which separate adjacent craters, and here constitute their walls. The outer slopes of the craters are gentle, the inner often nearly precipitous, this conformation being apparently due to the scoriæ having been ejected in a pasty condition, so that they stuck where they fell; and thus, while those which fell again directly into the fissure would be blown out again, those which fell out of the direct line attached themselves, and did not roll back, to fill up the vent, as we so often see in ash cones. These craters also illustrate most strikingly the fact that water, except as running streams, has scarcely any eroding power. Though they have been erupted over 100 years, their edges are as sharp and perfect as the day they were formed, the explanation being that the scoriæ are so porous, that the rain as it falls, and the snow as it melts, instantly soaks in, and never appears on the surface as a stream.

The lava near the craters is almost all of the corded or "*pahoheoe*" type, while, lower down the valley, immense fields of scoriaceous lava, or "*aa*," of the most bristling character are seen. The most probable explanation being that the lava, at the commencement of the eruption, contained much imprisoned steam and vapours, which escaped in fiery froth, and solidified into the rough "*aa*," and was carried down the valley on the surface of molten lava, which, in places, is as much as 600 feet thick. The eruption was a prolonged one, and consequently the later lava had a prolonged simmering in the chimney or fissure, during which it parted with most of its vapour, and when finally it flowed out it had little left, not sufficient to form a layer of froth, but only a few "giant's children" or blow holes, of which some very fine examples occur near the craters. This sequence of events does not appear always to obtain. Near Hekla we saw a stream of lava scoriaceous on the steep slope near its point of eruption, but corded with most beautiful regularity in parts where it had flowed tranquilly on the plain, after parting with most of its vapour, and escaping from under the crust higher up.

We returned from the Skapta by way of the Fjallabaksvegr, a desert route of about ninety miles from the last house on the one side to the first on the other, and thence by Hekla, the Geysir, and Thingvalla; but these have been often described, and space is wanting.

It is currently believed in Iceland, and was stated in some of the public prints at the time, that a volcanic eruption or earthquake had taken place at Cape Reykjanæs in October, 1887, by which a large new *giá* or chasm had been formed, separating a large rocky promontory, almost deserving the name of a mountain, from the main cape on which the lighthouse stands. This chasm, at least 50 feet wide, was pointed out to the author from a passing steamer, the captain declaring that he remembered the rocks before they were rent asunder. Here, then, appeared to be a case of the formation of one of the giás or chasms which form such a characteristic feature of Icelandic geology. There are several such on the Reykjanæs peninsula, huge chasms several feet wide, and of unknown depth, stretching for miles across the lava desert of which the district is composed. In this district they usually, though not always, have a throw of a few feet or yards, but one of these at Thingvalla, more in the centre of the island, the Allmanagiá, has a throw of about 100 feet. In this case, the author is satisfied that the *giá* is due to the unequal settling of a crust of lava formed on the surface of a still fluid mass, which had found an outlet and flowed out after the solidification of the surface. He is not prepared, however, to say that this explanation will hold good in the case of all the rifts on the Reykjanæs peninsula. It certainly would not in the case of the great fissure from which the Skapta lava was erupted. Consequently, any clear case of the formation of a new *giá* in strata long cooled and solidified, would have been well worth investigation.

From a careful examination of the locality, it appeared that no fresh formation of a *giá* has taken place, but that certain small portions of the rock on which the lighthouse stands had been loosened, partly by ordinary denudation, and partly by earthquakes, which are frequent here, and had fallen on to the

beach. The strata of partly consolidated volcanic ash, &c., are quite continuous at the end of the small cove or recess between the two large rocks above referred to.

DISCUSSION.

The CHAIRMAN said Dr. Anderson need not have apologised for bringing this paper before the Society, on the ground that the subject of volcanoes was not suitable for a Society dealing with arts, manufactures, and commerce, because many products of volcanoes were of great use in the arts. For instance, there was the volcanic ash called *pozzuolana*, which was quarried in Italy for making a very strong kind of cement, and deposits of a similar kind were worked on the banks of the Rhine, and exported to different countries. Then there was pumice-stone, and various building stones and paving stones were worked in France and Australia, which were simply volcanic lava. The old millstones, again, and querns were obtained from lavas on the banks of the Rhine, and obsidian was used in some countries for [illegible]ves and arrow heads. Then there was sulphur, [illegible] the jets of carbonic acid gas given off from holes in the ground near the Rhine were compressed into a liquid state, and sent to all parts of the world. Turning to Italy, again, boracic acid was obtained in the well-known district of the Maremma, and even the old quarries from which millstones had been quarried in Germany were found to make excellent cellars for cooling beer. Lastly, the four great deposits of diamonds in South Africa were supposed to be in the necks of old volcanoes. He could fully endorse Dr. Anderson's statement, that the Scotch boats were not to be depended on, for when he was stopping at the north-eastern corner of Iceland, the captain of the Scotch boat had promised to put in to pick him up on a certain day, but after waiting day after day, keeping a man out at night in a boat waiting for the steamer all in vain, he and his friend had to make their way across the island, by way of the Sprengisandr, a route which was hardly ever traversed; and when they did get a boat at Reykjavik, the navigation was very faulty, for they very nearly ran down the west coast of Scotland instead of the east. Dr. Anderson had omitted a picture of one of the public buildings of Reykjavik, of which he (the Chairman) was, for a short time, an inhabitant, viz., the jail, though, luckily, not as a prisoner. Having come across the Sprengisandr desert with his friend, and been about seven days without taking off their clothes, they were anxious, on arriving at the capital, to have a warm bath, but on making inquiries they found that the only place where such a luxury could be obtained was the jail, and they therefore went there, were hospitably received, and obtained what they wanted. He thought full justice had hardly been done to the Iceland ponies, which were exceedingly surefooted, and he had, after some misgivings, and being very much inclined to dismount, ridden down some most precipitous places, probably with more safety than he he could have secured on foot. These ponies were very clever also in going over marshes; on one occasion they were riding for some hours over a spongy marsh, where they expected every minute that the pony would be engulfed, but he was left to himself, and he managed, by some instinct, to pick his way over it in safety. Anyone going to Iceland, however, should be very careful about the stuffing of his saddle. An English saddler, used to a well-fed horse or pony, could hardly understand the kind of razor-backed animal you sometimes meet with in Iceland at the beginning of the season, which, having been half-starved during the winter, would be sure to get galled with an ordinary saddle. Dr. Anderson had been very fortunate with his guide, but he had not mentioned a matter which he (the Chairman) had found very annoying, and that was the difficulty in making a start. You might arrange overnight to start at seven in the morning, and be very lucky if you get off at eleven; and he recollected, on one occasion, having arranged to start at nine, they did not get away until three o'clock in the afternoon. There was one other bridge in the island besides the one which had been shown; this crossed a steep gully or chasm of the river Jökulsá near Seydisfjordr, and was known by the name of Brú, or bridge. He could endorse all that had been said as to the hospitality of the people. After starting on that unfortunate day, at 3 o'clock, and riding until 3 o'clock next morning, there being quite enough light in the summer time, they arrived at a farm house, and after waking up the people, the farmer got up with all his family, made them coffee, and his friend having the only bed in the guest room, he was conducted to an upper room, from which he judged by the surroundings that one of the farmer's daughters had only just been ejected. Sometimes they could not find sufficient accommodation in the farm houses, and, on one occasion, were then billeted in the church at Reykir, where they managed to sleep pretty comfortably. The guides were certainly excellent; they had one named Paul, who had the previous year accompanied Mr. Watts in his expedition, and he was thoroughly well qualified for his duties. When crossing the Sprengisandr on the worst day, when they had practically no food for the ponies, and one had to be killed, they had to cross 60 streams coming out of the glacier, and although the fords changed every year, and the guide had only been that way once or twice before, and not at all that year, he was able, by the look of the bank or the look of the water, to find where they could cross safely, and he gave them strict injunctions to follow exactly in his track; through failing to do so, his friend was very nearly washed away. Not only were Yorkshiremen of the same race as the Icelanders, but the inhabitants of the Isle of Man also came from the same stock, as was shown in the names. For instance,

Laxa, which simply meant a salmon river; and there was more than one Laxa in Iceland. There was, again, the further resemblance that, in the Isle of Man, the laws were promulgated in the open air, on the Tynwald-hill, once a year. They were much indebted to Dr. Anderson for this paper; and it was very interesting to a miner or geologist to see these photographs of great cracks and fissures, which enabled one to understand how similar operations had gone on in past times, and how they had subsequently become filled up with mineral matter.

Mr. E. MAGNUSSON said he could agree with nearly everything Dr. Anderson had said, though perhaps he had been inclined to generalise a little too freely. He had visited the part of the country which was most backward, being the most difficult of access; and therefore what he had seen there would not be true of the whole island. In some places the people, though descended from those who had long left the stone age behind, had found it necessary, because it was so difficult to procure iron, to create a new stone age for themselves. They were the creators of a new stone age, not the followers of a tradition. The volcanic nature of the country was exceedingly striking, the most interesting spot being the Thingvalla; and he would call attention to one peculiarity of it, which Dr. Anderson had perhaps observed. The valley was bounded on the two sides by two enormous rifts, the western being called "The Rift of the People," and the eastern, "The Raven's Rift." Between these two rifts the valley of Thingvalla fell down in a scoop, and it was evident that at one time the whole valley had been a volcanic bubble, and instead of being formed, as Dr. Anderson seemed to think, at the time the lava was flowing, he thought it was formed through a natural catastrophe—an earthquake—in later times, long after the lava itself had formed a strong roof over it. The proof of that could be seen in the fact that when you travelled over the lower part of the valley, you found that the roof, when it came down, split up into endless fragments, the cracks between which were filled up everywhere by the bottomless water rifts which had been mentioned. The history of the sulphur business in Iceland was not very commendable, and the less people were encouraged to believe that sulphur was to be had in Iceland the safer they would be. No doubt there were sulphur incrustations on the inside of the craters, but all geologists were agreed that the sulphur in the country was not a commercial article; it was not merely that it was difficult to get at, it was simply not there. Considering the short time Dr. Anderson had spent in the country, it was wonderful how he had observed so much, and how few errors he had made. One slight mistake was to suppose that the scythe he had seen standing against the wall of a farmhouse was one of a pair of stilts; the Icelandic scythe was a peculiar instrument, and looked very much like a stilt when turned upside down.

Mr. OLIVER WILLIAMS asked if the farmers in Iceland were much occupied in cattle rearing, or did they confine their attention chiefly to ponies. Also, if cement which could not be made there for want of fuel could be used if it were imported, or would the severe weather prevent it setting. He was glad to notice Dr. Anderson's reference to the bad effect of idleness, both in diminishing stature and in affecting the power to work, and would like to know if he thought it had at all affected the brains of the people. He had not been in Iceland, but had experienced just the same kind of hospitality in Siberia as had been mentioned by the Chairman.

Mr. JONATHAN HUTCHINSON, F.R.C.S., asked if Dr. Anderson could give any information as to the prevalence of leprosy in Iceland, a disease which still prevailed in Norway, and had only disappeared from our own island and the Orkneys within comparatively recent times. If it had disappeared in Iceland it would be very interesting to know under what circumstances it had done so, and if any change had taken place in the social habits of the people which would account for it. They were told by some that it was rapidly disappearing in Norway owing isolation and the prevention of contagion, but believed it was disappearing still more rapidly in Iceland, where no such measures were taken. There were two theories on this matter, one that it disappeared through the prevention of contagion, the other that it was owing to a change in the habits and particularly in the diet of the people, and that the disease was due to the consumption of badly salted fish. Now Bergen, in Norway, had the largest leper hospital in the world, and the largest fish market in the world, and it sent its fish to Naples and many other places where leprosy was still occasionally met with. Iceland seemed to be just the place for collecting evidence on this point.

Mr. DONALD suggested that the diminutive stature of the people might be partly accounted for by intermarriage, which would probably be prevalent in such a population.

Mr. WILLIAM GEORGE LOCKE said the Rev. Mr. McCormick, of Brighton, was just about publishing a book giving an account of his researches on leprosy in Iceland, which he had visited for the express purpose of studying the subject. He obtained a good deal of information from Mr. Paterson, the British Consul, and also from Dr. Skiding, and it appeared that, in 1800, out of a population of 50,000 there were 150 lepers; and now, out of a population of 72,000, there were only 25. On further inquiry, however, from an older and more experienced doctor, he was told that the disease was increasing, and that 1 per 1,000 suffered from it. There were no hospitals for leprosy, though Dr. Anderson who travelled through the island in 1824, said there were then four. Lepers were forbidden to marry, as the disease

was considered hereditary; but it was difficult to ascertain the actual state of affairs as the authorities did not like to say much about it. He (Mr. Locke) congratulated Dr. Anderson on his excellent paper, and the photographs which illustrated it. He had travelled in the country several times, and had read everything about it published in English, and a good deal in Danish. There were 30 volcanoes which had been active in historic times; and he believed no Englishman before had penetrated to the source of the lava that came out of the Shapka in the great eruption of 1793.

The CHAIRMAN then proposed a vote of thanks to Dr. Anderson, which was carried unanimously.

Dr. ANDERSON, in reply, said there was one useful purpose served by volcanoes which the Chairman had omitted to mention. At Santa Cruz, in the Canary Islands, a volcanic mass had risen two miles out to sea, and formed an excellent natural harbour. If the next eruption in Iceland would put out a nice barrier of lava, with a neck connecting it with the shore about the middle of the southern coast of Iceland, the volcano would do a great deal to redeem its character. He had the same experience of the Scotch boat as the Chairman; it did not come to take him at the time appointed, and he would have had a fortnight to wait but for the sailing of a cargo boat. The captain even of that refused to take him, but having the misfortune to fall down and break his leg the next morning, he was very willing to give a doctor a free passage in return for his surgical aid. He could not say anything about cattle rearing, but he saw very few cattle there at all; the live stock were chiefly sheep and ponies, and he heard from the guides that the farmers knew nothing about breeding the latter, but simply let them run wild, which accounted for the number of curious looking animals to be seen.

Mr. MAGUNSSON said the cattle ranged from one to forty on a farm, but they were not much seen.

Dr. ANDERSON said he certainly did not see many. He should imagine there would be no difficulty in using cement, as the weather was comparatively warm in summer. Mr. Williams had slightly misapprehended him. He did not attribute the weakness and small stature of the inhabitants to idleness, but to want of food and hardship continued from generations; and he thought their brains were quite equal to the average. Every Icelander could read, which was greatly to their credit, considering the difficulty of teaching in so scattered a population. Even in the poorest hovels you would see a nice little library. Intermarriage might have some influence, but he could not say anything about that for certain. With regard to leprosy, one doctor told him there were 40 or 50 cases in the island, but he seemed to be an official at Reykjavik, and he probably minimised it, because he told him of at least two or three more. The people soon found out that he was a doctor, and he was generally delayed for three-quarters of an hour or more in the morning by the large number of patients, with all kinds of extraordinary diseases, who were brought to be examined; there were two or three cases of coccuscysts, and several leper cases. One young woman came with a curious affection of the muscles of the thumb, which his friend thought was a case of atrophy, but remembering what he had seen at Bergen he said he should not be surprised if it was a case of leprosy, and asked her if she had any spots about her. She denied it, but in about half an hour her conscience struck her, and she came back and said she had, and he found on the arm one of the characteristic painless spots which, corresponding with the atrophy of the muscle, was the early sign of leprosy. But in the presence of such an authority as Mr. Hutchinson he did not feel that he could say anything of any value on this subject. These people were on the seashore and were probably fish eaters, but everybody on the island was more or less near the seashore, and probably ate fish.

Miscellaneous.

LIVE STOCK AT THE CHICAGO EXHIBITION.

The following letter on the exportations of pedigree live stock to America has been addressed by Mr. Ernest Clarke, on behalf of the Agricultural Committee of the Royal Commission for the Chicago Exhibition of 1893, to the Royal Commissioners, and has been forwarded by them to Chicago for the consideration of the authorities of the Exposition:—

12, Hanover-square, London, W.,
15th March, 1892.

SIR,—1. In compliance with the request of the Royal Commission for the Chicago Exhibition of 1893, the Agricultural Committee have been for some time engaged in endeavouring to stimulate public interest in the work of the Agricultural Department of the Exposition, and in particular, to attract entries from the breeders of this country for the Shows of Live Stock which are to be held in connection with the Exposition in the autumn of 1893.

2. The councils of several of the more important of the breed societies of the kingdom have already communicated to the Committee their wish to offer champion prizes or gold medals for the best specimens exhibited of their respective breeds, and the Committee had reason for hoping that this example would have been very generally followed.

3. They cannot but feel, however, that the Order

of the 22nd January, 1892, issued from the United States Treasury Department with regard to importations of animals for breeding purposes, not only prejudices the offers of champion prizes already received by the Committee, and makes improbable the receipt of others, but is likely to interfere very seriously with the chances of an adequate representation of the British breeds of live stock at the Exposition.

4. The Order in question directs that "On and after April 1st, 1892, no animal which is brought into the United States from foreign countries for breeding purposes shall be admitted free of duty, unless the importer furnishes a certificate which shall contain a pedigree in the form hereafter given, showing that the ancestors have been recorded in a book of record established for that breed for five generations on the side of the sire, and four on the side of the dam." . . . . "Unless such certificate of pedigree is produced, therefore, the animal shall be considered dutiable as not being pure-bred of a recognised breed, and duly registered in the book of record established for that breed." The form of certificate required to be furnished by the importer has spaces not only for the animal itself and its stud or herd-book number, but for the pedigrees (with numbers) of five generations of ancestors on the side of the sire, and four generations on the side of the dam, and it must be signed by the secretary of the stud or herd-book as a correct pedigree of the animal.

5. The Committee think the Treasury Department can hardly have been aware, when promulgating this Order, that its effect will be to create a distinction (absolutely unjustified by facts) between the breeds of live stock recognised in this country as pure. With but few exceptions, the conditions of admission of animals to the British stud or herd books mentioned in the Treasury Order do not exact a pedigree so lengthy as that contemplated by the Order. Although in certain particular cases, where the pedigrees of their animals have for a long period been carefully recorded by individual breeders, it might be possible for secretaries of stud or herd books officially to fill up the required certificate, yet in the great majority of instances such a certificate could not be obtained by the importer, notwithstanding that his animal had been duly accepted by the responsible authorities of the British book of record of the particular breed as a pure-bred animal, qualified for entry in their stud or herd book.

6. The interest of the Agricultural Committee of the Royal Commission in this matter is of course confined to the probable effect of the Order upon the number of animals sent over from this country to compete at the Live Stock Shows in connection with the Chicago Exposition, though, largely consisting as the committee does of the representatives of the different British breeds of live stock, it cannot ignore the very serious consequences which the enforcement of the Order will have upon the exportations of pedigree animals from this country to America.

7. The cost and difficulties of sending animals to the Chicago Exhibition are already so great, that none but those who see a prospect of selling the animals sent, or others of the same kind from their studs or herds, are likely to be attracted to send entries. And if, to these difficulties, be superadded an import duty, which animals of one particular breed escape, and animals of another equally pure and well-established breed have to pay, the Committee feel that, so far as this country is concerned, the expressed aspiration of the Chicago Executive, that "every species, breed, variety, or family of animals, domesticated or otherwise, throughout the world, be represented at the Exposition," will not be satisfactorily realised.

8. The Committee have therefore instructed me to communicate their views on the subject to the Royal Commissioners, and to suggest that the Chicago Executive should be invited to ascertain and state specifically whether the Treasury Order of the 22nd January, 1892, which refers to the importation of animals "for breeding purposes," will be held to apply to animals sent from this country to Chicago "for *exhibition* purposes."—I am, Sir, your obedient servant,

(Signed) ERNEST CLARKE,
Honorary Secretary.

The Secretary
of the Royal Commission,
for the Chicago Exhibition.

RUSSIAN SUNFLOWER INDUSTRY.

The sunflower, as a garden plant, has been known all over Russia for many years, but only in certain districts has it been cultivated on a large scale as an industry. The first cultivation of sunflower seed for commercial purposes began, says the United States Consul General, at St. Petersburg, in 1842, in the village of Alexeievka, in the district of Berutchinsk, Government of Voronezh, by a farmer who was the first to obtain oil from the seed. This farmer soon found many followers, and the village of Alexeievka soon became the centre of the new industry. The Government of Voronezh is even now the chief district in European Russia for the growing of the sunflower. Besides the district of Berutchinsk, this plant is cultivated on a large scale in the districts of Novokhopersk, Ostrogoshk, Bobroosk, Valouisk and Korotoiaks. From the government of Voronezh the cultivation of sunflowers spread to the adjacent governments of Tamboo and Saratov, where there are large fields cultivated with this plant, particularly in the latter government. The people of the province of the Don and the government of Simbersk and Samara are more or less engaged in this tiade, in fact in the entire south-east of Russia the sunflower furnishes a prominent product of the farm. Two kinds of sunflower are grown in Russia—one with small seeds, used for the production of oil, and the other with larger seeds, con-

sumed by the people in enormous quantities as dainties. In the district where the seed is cultivated on a large scale, the plant has been continually grown on the same soil for many years in succession, thus producing a special disease of the plant. The sunflower seed is used principally for obtaining sunflower oil, which, owing to its nutritious qualities, purity, and agreeable flavour, has superseded all other vegetable oils in many parts of the country. In general, the cultivation of the sunflower in Russia is considered to be very profitable. At the average yield of 1,350 lbs. to the acre, and at the average price of ¾d. a pound, the farmer receives an income of about £4 an acre, and this income can be increased in those districts where the grower himself is engaged in producing the oil from the seed. The substance remaining from the oil manufacture, or sunflower cakes, being used as cattle food, is also a valuable product. These cakes, however, have a comparatively small demand in Russia, but are largely exported to foreign countries, principally to Germany and England. The Government of Saratov, for instance, exports about 2,000,000 lbs. of sunflower cakes to different countries, where a further quant[illegible] oil is extracted from them before being used [illegible]tle food. The sunflower shells being used fc[illegible]ing purposes, form an article of trade in several districts. The seed cups are not wasted, but are used as food for sheep. The peasants in the Government of Tambov are increasing the cultivation of the sunflower owing to the following reasons. There is a steadily increasing demand at home and abroad for the seed, thns making the industry a profitable one, especially as Russia is the chief source of supply. As above mentioned, the sunflower is cultivated principally for the oil. If the cultivation is made with care, and if proper precautions are taken in drying, cleaning, and pressing, sunflower oil is equal to the French table oil in colour, flavour, and taste. At first sunflower oil did not meet with public favour in Russia, but later on, owing to its good qualities and cheapness, it took the place of the oil of poppy seed; but for a long time hemp-seed oil competed with it, owing to the fact that the lower classes, who for many years had used the hemp seed oil in the preparation of various dishes, and who had long learnt to relish it, were not disposed to give it up. Now, however, public opinion has changed, and sunflower oil is preferred by the masses to all other table oils in Russia. The process of oil-making is as follows. The seed being brought to the oil mill, is thoroughly cleaued and sorted. They are passed under millstones, specially prepared for the purpose, in order to release the seed from the shells. After this the seed is properly dusted and put under a press, and, later on, into a mixer, where the seed is turned into a compact mass very much like paste, which passes into vessels heated by steam. From these vessels the paste is taken out and wrapped in a thin web, made of camel hair, and put under a press, by which the oil is squeezed out and conducted by pipes into tanks. The total number of oil mills in Russia was, according to the last account, 104. From this number 85 were applied solely to obtaining sunflower oil. In 24 of these mills steam is used, and in others only manual power. The largest mill is at Saratov, and it produces 1,500,000 pounds of oil annually. There are two kinds of oil obtained from the sunflower seeds. The better kind is sweet, and more expensive, the inferior having a bitter taste. The difference in the price of these two qualities is about one halfpenny a pound. The oil remaining from the oil production or the waste, and not used as food, is applied exclusively to certain industries. The sunflower stalks, gathered from the fields, and dried in piles, have entirely replaced firewood; in fact, these stalks are preferred even to pinewood, producing a quick and hot-flame fire. About 2,000 pounds of such firewood are gathered from an acre of land, thus adding a great boon to a district where wood is scarce. Sunflower shells are also used for heating purposes, not only in private houses, but in large factories as well. They are burned in ovens specially prepared for their consumption. The ashes of the sunflower contain a high percentage of potassium. The experiments of Hermbstedt have proved that 1,000 pounds of dried stalks yield 57·2 pounds of ash; and from 1,000 pounds of ash are obtained 349 pounds of the best potassium. As a food for cattle, sunflower cakes are looked upon as the best in Russia; they are considered better even than hemp or rape-seed cakes. According to chemical analyses, the sunflower cakes from the Government of Saratov contain:—Azotic substances, 42·31 per cent.; oil, 14·7 per cent.; and ashes, 5·12 per cent. The dried seed-cups, if ground, are used in many districts as food for cattle, and particularly for sheep, with great success.

PALM OIL.

The total import of palm oil into England is about 50,000 tons, valued at over £1,000,000, but it is considered that this is an exceedingly small commerce compared to what might be the case were the enormous resources fully, or even moderately, utilised. For miles along the west coast of Africa, extending between Cape Bianco and St. Paul di Loando, there are vast forests of palms, the oleaginous fruit of which has, for centuries, rotted unused upon the ground. The oil palm forests at the back of the coast line of Cape Palmas and Elmina are said to be practically inexhaustible; and so also in the neighbourhood of Fernando Po, immense tracts are covered with the trees.

Lagos furnishes the purest oil; for there are in commerce regular and irregular oils. When analysed, if the water and impurities exceed 2 per cent., an allowance is made; for often these oils contain 10 to 15 per cent. of water and impurities.

Palm oil is eaten as butter by the natives, and used for anointing their bodies. Here it is used in the manufacture of soap and candles, and in South Wales in the preparation of tin plates. Its non-drying qualities render it valuable as a preservative of the surface of the heated iron sheet from oxidation until the moment of dipping into the bath of melted tin, the sheets being rapidly transferred to that from the hot oil bath, which consists almost entirely of palm oil.

In 1871, as well as in 1880 and 1891, the imports of palm oil into the United Kingdom exceeded 1,000,000 hundredweight. From 10,000 to 15,000 tons of palm oil are shipped direct from Africa to the Continent. The price of the oil has ranged from 35s. per cwt., in 1883, to 23s., in 1890.

Correspondence.

INDIA AND THE HYGIENE CONGRESS.

Sir William Moore is mistaken as to the authorship of the paper on "Indian Factory Legislation," read at the Hygiene Congress. The official "Reports of the Meetings and Discussions" show that the only paper on the subject was read by me, and that Dr. Bahadhurji, the delegate of the Bombay Millowners' Association, merely joined in the discussion. Dr. Bahadhurji has since greatly added to and amplified his remarks, and published them under the title of "Factory Labour in Indian Spinning and Weaving Mills: Paper read before the Congress of Hygiene and Demography"—rather an Oriental way of proceeding. Dr. Bahadhurji's statements in this publication, and in letters to the Press, have been contradicted and disproved *seriatim* by Mr. N. M. Lockhanday, President of the Bombay Mill Hands' Association, who was appointed Local Member of the India Factory Commission of 1890 for the Presidency of Bombay. The value of Mr. Lokhanday's judgment upon the discussion between Dr. Bahadhurji and myself is evidenced from the way his appointment was alluded to in a leading article of the *Bombay Gazette*, where it was stated that "Mr. Lokhanday, though no longer connected with the mills, was for some years an operative, and he has since been in constant contact with the mill-hands. It is easy enough to call him a professional agitator, but he stands alone as an educated man able to give expression, from his personal knowledge, to the facts of mill life, and to the wishes of the mill operatives." In his series of articles on the subject, which appeared in the *Din Bandhu* between October 25th and December 20th, 1891, Mr. Lokhanday endorsed my statements. This is not surprising, as they were taken from Blue-books and other official publications, containing the reports of experienced and trained factory inspectors, sent out from England to inspect and report upon Indian factories, and the evidence given before various Factory Commissioners in India by medical men, mill managers, and operatives, whose evidence has never been publicly challenged or controverted. Dr. Bahadhurji has been in no way officially or in his private practice connected with the mills. His knowledge of them is recent, and was gained in a few flying visits, in order to represent the Bombay mill-owning interest before the Congress, and his statements are referred to by the acknowledged expert, Mr. Lokhanday, as "a patchwork of misstatements and contradictions."

HOLT S. HALLETT.

1, Chilworth-street, W.

Obituary.

DR. TIDY.—Charles Meymott Tidy, M.B., the eminent chemist and analyst, died on Tuesday night, 15th inst. He was a son of the late William Callender Tidy, M.D., of Hackney, and for a short time continued his father's practice at that place. He became a member of the Royal College of Surgeons in 1864, and took his M.B. degree in 1866. Shortly afterwards he was appointed joint lecturer on chemistry with the late Dr. Letheby, at the London Hospital, and subsequently he became Professor of Chemistry and of Medical Jurisprudence and Public Health at the same hospital. He was, at the time of his death, Official Analyst to the Home-office and Medical Officer of Health for Islington. Dr. Tidy was a member of the Society of Arts. H. delivered a course of Cantor Lectures on the "Practical Application of Optics to the Arts and Manufactures and to Medicine," in November and December, 1873; and on April 14th, 1886, he read his elaborate paper on "The Treatment of Sewage," which was discussed at three adjourned meetings, viz., on May 5th, and December 1st, and 15th, 1886. In 1889, the Swiney Prize was awarded to Dr. Tidy for his work, entitled "Legal Medicine." In 1872, he, in conjunction with Dr. Woodman, read a paper before the Royal Society, on "Ammonia in the Urine in Health and Disease." He published, in 1878, a "Handbook of Modern Chemistry," a second edition of which appeared in 1887. Dr. Tidy was called to the Bar at Lincoln's-inn a few years ago, and he held the office of Reader of Medical Jurisprudence to the Inns of Court.

General Notes.

DURABILITY OF MODERN PIGMENTS.—It is to be regretted that a sentence commenting adversely upon a painting medium sold by a particular manufacturer,

should have been allowed to appear in a letter, printed on page 387 of last week's *Journal*. Messrs. Charles Roberson & Co., the manufacturers of the medium, has complained to the Secretary of the criticism in question. Under these circumstances, it seems only fair that an opportunity should be given for the defence of the article which has been attacked. Messrs. Roberson refer to a note which appeared in the *Athenæum* of July 21st, 1866, in which the late Mr. E. M. Ward, R.A., stated that the whites in his well-known picture of the South Sea Bubble, painted 20 years before with Roberson's medium, were at that time as pure and as brilliant in its character as on the day the picture was painted. This picture is now in the National Gallery, Trafalgar-square, so that persons interested in the subject can judge for themselves whether there has been any degradation of the original brilliancy. Messrs. Roberson further state that as this medium has been extensively employed as a vehicle in oil painting for more than fifty years, any number of examples of its durability may be referred to.

RECEIPTS OF PARIS THEATRES IN 1891.—According to a report in the last number of the *Bulletin de Statistique et de Legislation Comparée*, the gross receipts of all the places of entertainment in Paris in 1891 amounted to £943,986, as compared with £920,536 in 1890, and £1,285,556 in 1889. It should, however, be remembered that the latter was the Paris Exhibition year, when the receipts of the various places of amusement would naturally exceed those of an average year. During last year the largest amount realised by any of the places of entertainment in Paris was £122,738—taken at the Opera-house, a building capable of holding 2,200 persons. The next in order of importance was the Comédie Française with £79,140; and after it came the Opéra Comique with £70,523; the Hippodrome with £63,295; the Théatre des Variétés with £45,320; and the Bouffes Parisiens with £45,222. At the Nouveau Cirque £37,100 were taken; at the Cirque Franconi, £29,972; and at the Folies Bergère, £28,850.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock:—

MARCH 23.—GILBERT R. REDGRAVE, "Manufacture and Industrial Application of Flexible Tubing." Sir FREDERICK BRAMWELL, Bart., D.C.L., F.R.S., Deputy Chairman of the Council, will preside.

MARCH 30.—EWING MATHESON, "Foreign Exchange."

APRIL 6.—ROBERT S. MCCORMICK, Resident Commissioner for Great Britain from the World's Columbian Exposition, "The Future Trade Relations of Great Britain and the United States."

APRIL 13.—Prof. ROBERT WALLACE, "Egyptian Agriculture."

Papers, the dates of reading of which are not yet fixed:—

"The Fisheries Department: its Position and Prospects." By J. W. WILLIS BUND.

"The Congo State." By Captain V. LOVETT CAMERON, R.N., C.B.

"Colour Blindness." By Captain W. de W. ABNEY, C.B., F.R.S.

"Uses and Applications of Aluminium." By G. L. ADDENBROOKE.

FOREIGN AND COLONIAL SECTION.

Tuesdays, at Half-past Four or Eight o'clock; due notice of the hour will be given:—

APRIL 5.—The Rev. JOHN MCLEAN, D.D., "The Red and White Races in Manitoba and the North-West." The paper will be illustrated by lantern slides, and a collection of Blackfoot and Sioux Indian articles. 8 p.m.

APRIL 26.—Sir EDWARD BRADDON, K.C.M.G., "Australasia: its Progress and Resources." 8 p.m.

MAY 24.—Colonel HOWARD VINCENT, C.B., M.P., "The Extension of Colonial Trade." 8 p.m.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

MARCH 24.—G. H. M. BATTEN, formerly of the Bengal Civil Service, "The Opium Question." Sir JOHN STRACHEY, G.C.S.I., C.I.E., will preside.

APRIL 7.—Dr. J. AUGUSTUS VOELCKER, "The Agricultural Needs of India."

APRIL 28.—Sir WILLIAM WEDDERBURN, Bart., "Reorganisation of Agricultural Credit in India."

MAY 19.—JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock:—

MARCH 29.—E. ROSCOE MULLINS, "The Decorative Uses of Sculpture." ALFRED GILBERT, A.R.A., will preside.

APRIL 12.—C. PURDON CLARKE, C.I.E., "English Brocades and Figured Silks." The LORD MASHAM will preside.

MAY 17.—GEORGE J. ROBINSON, "Decorative Plaster Work" (II.). J. HUNGERFORD POLLEN will preside.

MAY 31.—WILLIAM DE MORGAN, "Lustre Ware."

CANTOR LECTURES.

Monday evenings, at Eight o'clock:—

PROF. WILLIAM ROBINSON, M.E., Assoc-M.Inst.C.E., "The Uses of Petroleum in Prime Movers." Four Lectures.

LECTURE IV.—MARCH 21.—*Oil Fuel and Gaseous Fuel for Steam-boilers.*—Safe heavy oils available—Different methods of burning oils—Injector-burners—Evaporative power of oil fuel.—Advantages and disadvantages of liquid fuel on steamships—Transport and storage of petroleum—Other uses of petroleum for power purposes.

BENNETT H. BROUGH, Assoc.R.S.M., F.G.S., "Mine Surveying." Three Lectures.

LECTURE I.—MARCH 28.—*Introductory.*—Nature of mineral deposits, and the modifications of the methods of surveying required in different mines—Accidents due to inaccurate surveying—Historical sketch—The oldest mine plan—The divining rod—The use of the magnetic needle in mapping deposits of iron ore.

LECTURE II.—APRIL 4.—*Surveying.*—The compass—Ancient forms of compass—Various forms of miner's dials and theodolites—Use of aluminium for mine-surveying instruments—Supply of light for reading the verniers underground.

LECTURE III.—APRIL 11. — *Levelling.* — The level and staff for underground use—Applications of levelling in mining operations—The Carrara marble railway—Aërial wire ropeways—Hydraulic mining ditches—The St. Gothard, Mont Cenis, and Croton aqueduct tunnels—The Ernst-August adit-level—Mapping bore-holes.

DR. PERCY FRANKLAND, F.C.S., "Recent Contributions to the Chemistry and Bacteriology of the Fermentation Industries." Four Lectures.

May 2, 9, 16, 23.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 21...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Prof. William Robinson, "The Uses of Petroleum in Prime Movers." (Lecture IV.)

British Architects, 9, Conduit-street, W., 8 p.m. Prof. Aitchison, "Byzantine Art."

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 1A, Adelphi-terrace, W.C., 8 p.m. Dr. Phené, "Certain Traditions in Heathen Mythology."

London Institution, Finsbury-circus, E.C., 5 p.m. Dr. Klein, "Bacteria, their Nature and Functions."

TUESDAY, MARCH 22...Camera Club (at the HOUSE OF THE SOCIETY OF ARTS), 3 p.m. Annual Conference. Opening Address by the President; reading of papers and discussion. 8 p.m. Confereuce continued. Demonstration of Electric Light Photographs, by Mr. Van der Weyde.

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Victor Horsley, "The Brain." (Lecture X.)

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Alex. R. Binnie, "Mean or Average Annual Rainfall, and the Fluctuations to which it is Subject."

Photographic, 5A, Pall-mall East, S.W., 8 p.m.

Anthropological, 3, Hanover-square, W., 8½ p.m. Mr. J. Theodore Bent, "The Archæology of Zimbabwe Ruins."

WEDNESDAY, MARCH 23...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Gilbert R. Redgrave, "Manufacture and Industrial Application of Flexible Tubing."

Camera Club (at the HOUSE OF THE SOCIETY OF ARTS), 3 p.m. Conference. Reading of Papers, and Discussion (continued).

Geological, Burlington-house, W., 8 p.m.

Royal Society of Literature, 20, Hanover-square, W., 8 p.m. Dr. R. A. Douglas Lithgow, "Anglo-Saxon Alliterative Poetry."

THURSDAY, MARCH 24...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Mr. G. H. M. Batten, "The Opium Question."

Camera Club (at the HOUSE OF THE SOCIETY OF ARTS), 8 p.m. Lantern Slide Exhibition.

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

London Institution, Finsbury-circus, E.C., 6 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. B. A. Whitelegge, "Epidemic Waves." (Lecture I.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m.

FRIDAY, MARCH 25 ... United Service Inst., Banqueting-house, Whitehall, S.W., 3 p.m. Colonel T. B. Shaw-Hellier, "The Organisation of Military Bands, and on Military Music." The lecture will be illustrated by the Kneller-hall Band.

Royal Institution, Albemarle-street, W., 8 p.m. Wekkly Meeting, 9 p.m. Dr. John Evans, "Posy Rings."

Civil Engineers, 25, Great George-street, S.W., 7½ p.m. (Students' Meeting.) Mr. G. Lambert Gibson, "The Seafield Dock and the Kirckaldy and District Railway."

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Science Schools, South Kensington, S.W., 5 p.m. 1. Prof. Herroun, "The Electro-motive Forces of Gold and Platinum Cells." 2. Mr. E. S. Bruce, "A New Instrument for showing the Effects of Persistence of Vision." 3. Mr. R. W. Paul, "Some Electrical Instruments."

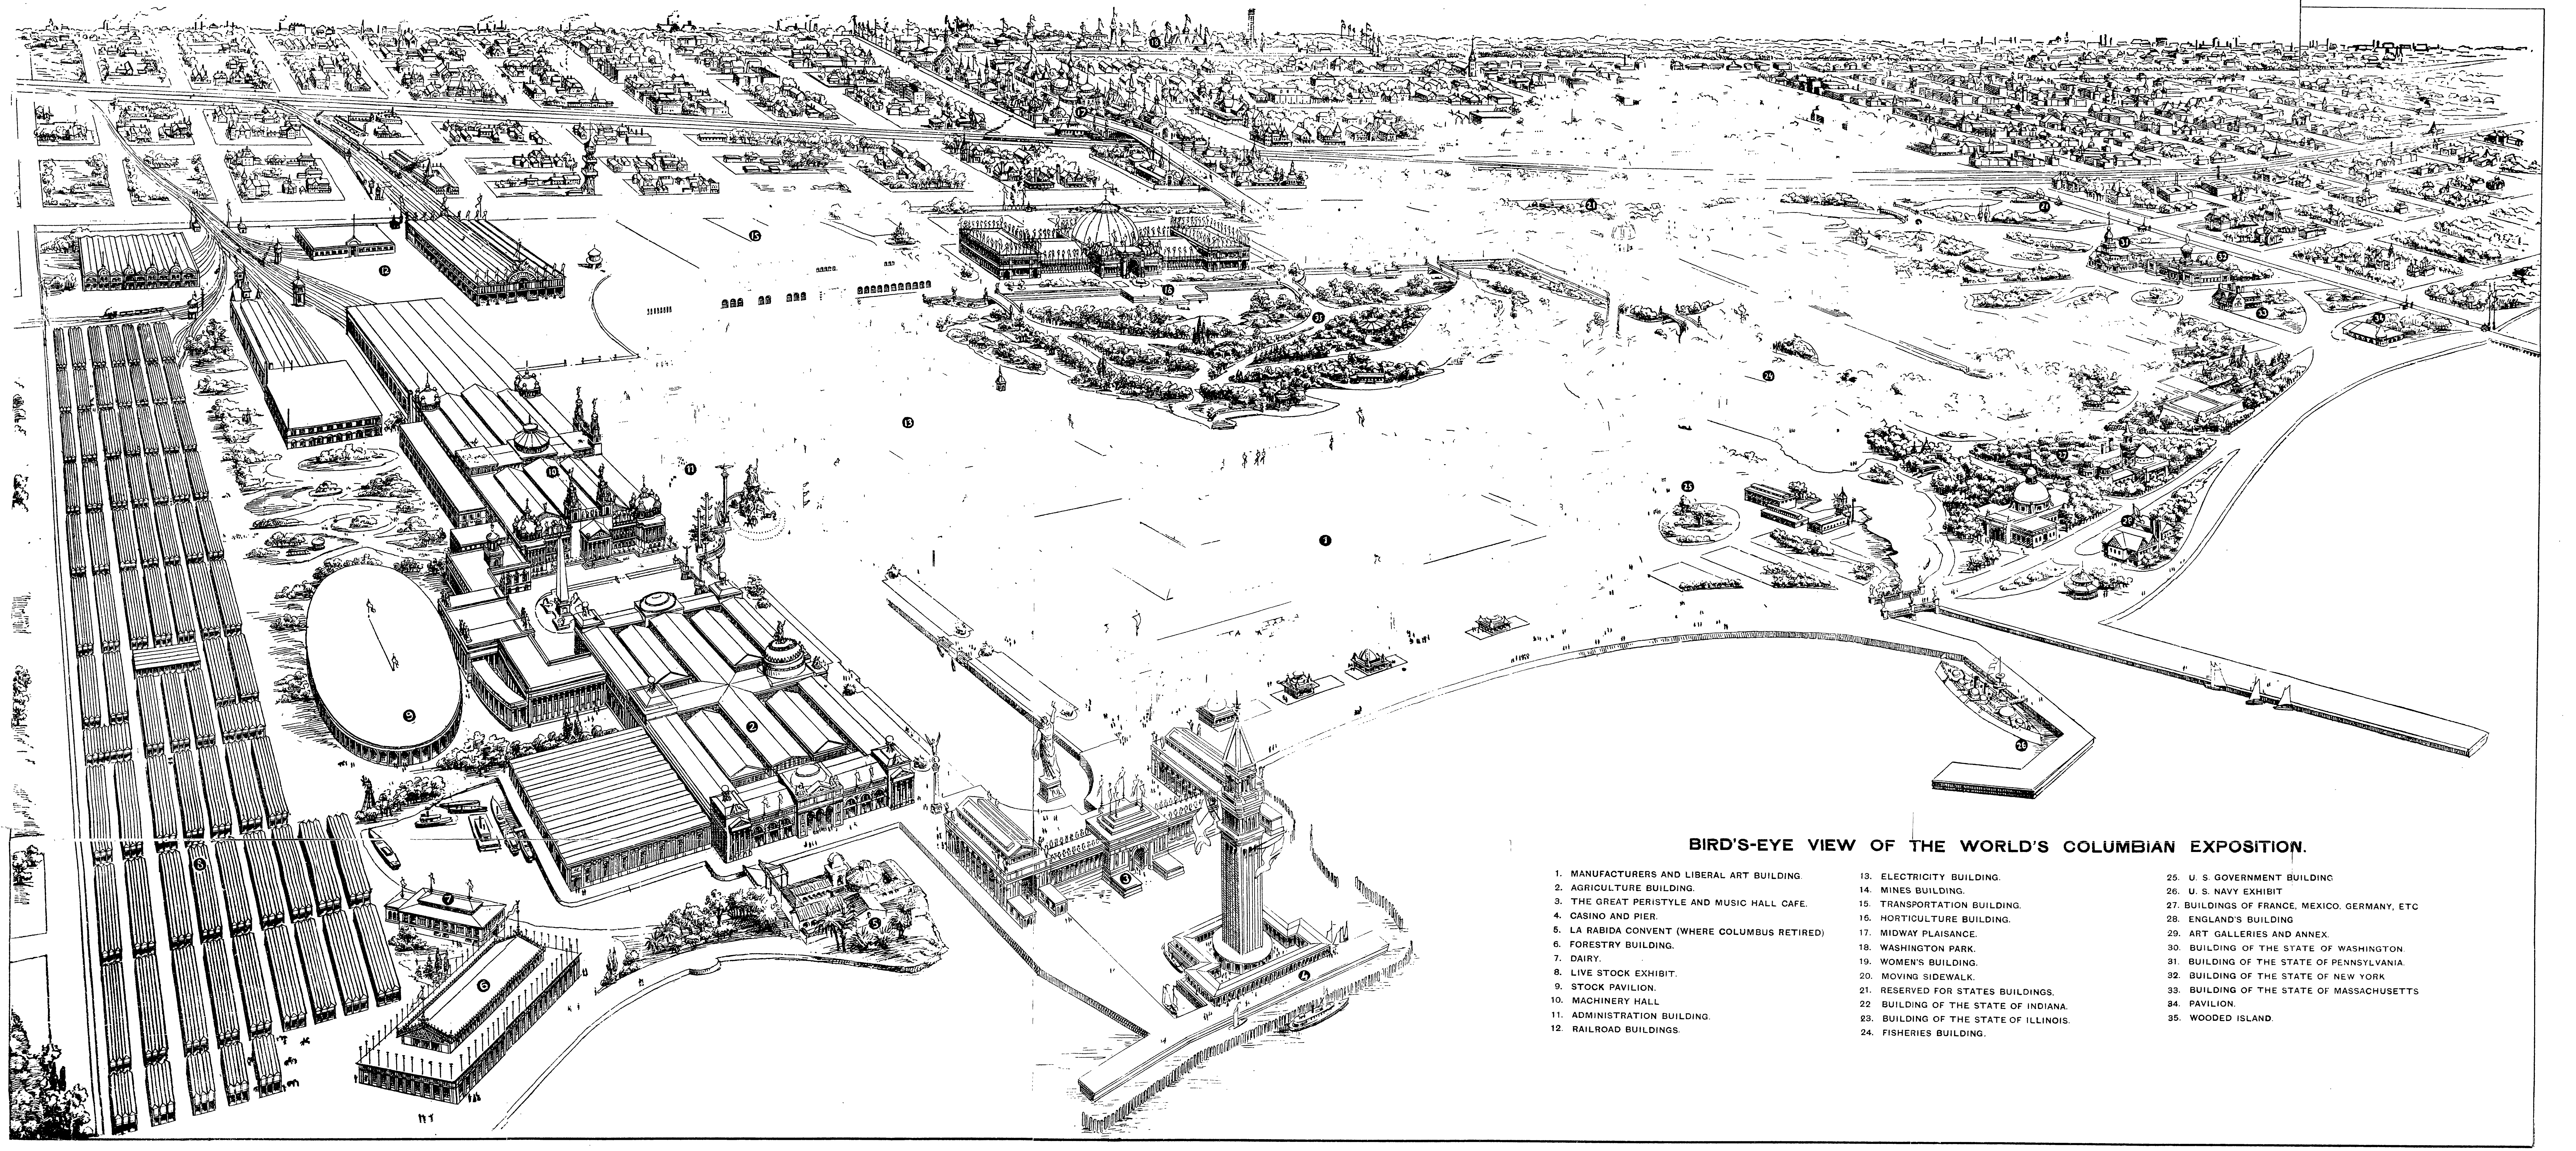
SATURDAY, MARCH 26...Saturday Lecture Society, Lecture Theatre, South Kensington Museum, S.W., 3 p.m. Prof. J. Norman Lockyer, "Astronomy and Mythology of the Ancient Egyptians." Lecture I.

Botanic, Inner Circle, Regent's-park, N,W., 2 p.m. First Spring Exhibition.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. J. F. Bridge, "Dramatic Music from Shakspere to Dryden."

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

SUPPLEMENT TO THE JOURNAL OF THE SOCIETY OF ARTS, 25TH MARCH, 1892.



BIRD'S-EYE VIEW OF THE WORLD'S COLUMBIAN EXPOSITION.

1. MANUFACTURERS AND LIBERAL ART BUILDING.
2. AGRICULTURE BUILDING.
3. THE GREAT PERISTYLE AND MUSIC HALL CAFE.
4. CASINO AND PIER.
5. LA RABIDA CONVENT (WHERE COLUMBUS RETIRED)
6. FORESTRY BUILDING.
7. DAIRY.
8. LIVE STOCK EXHIBIT.
9. STOCK PAVILION.
10. MACHINERY HALL
11. ADMINISTRATION BUILDING.
12. RAILROAD BUILDINGS.
13. ELECTRICITY BUILDING.
14. MINES BUILDING.
15. TRANSPORTATION BUILDING.
16. HORTICULTURE BUILDING.
17. MIDWAY PLAISANCE.
18. WASHINGTON PARK.
19. WOMEN'S BUILDING.
20. MOVING SIDEWALK.
21. RESERVED FOR STATES BUILDINGS.
22 BUILDING OF THE STATE OF INDIANA.
23. BUILDING OF THE STATE OF ILLINOIS.
24. FISHERIES BUILDING.
25. U. S. GOVERNMENT BUILDING
26. U. S. NAVY EXHIBIT
27. BUILDINGS OF FRANCE, MEXICO, GERMANY, ETC
28. ENGLAND'S BUILDING
29. ART GALLERIES AND ANNEX.
30. BUILDING OF THE STATE OF WASHINGTON.
31. BUILDING OF THE STATE OF PENNSYLVANIA.
32. BUILDING OF THE STATE OF NEW YORK
33. BUILDING OF THE STATE OF MASSACHUSETTS
34. PAVILION.
35. WOODED ISLAND.

Journal of the Society of Arts.

No. 2,053. Vol. XL.

FRIDAY, MARCH 25, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CANTOR LECTURES.

The fourth and last lecture of the course on "The Uses of Petroleum in Prime Movers" was delivered by Prof. William Robinson, M.E., Assoc. M.Inst.C.E., on Monday evening, 21st inst.

On the motion of the Chairman (Mr. W. H. Preece, F.R.S.), the thanks of the meeting were voted to the lecturer for his valuable course of lectures.

The lectures will be printed in the *Journal* during the summer recess.

Chicago Exhibition, 1893.

MEETING OF THE ROYAL COMMISSION.

A meeting of the Royal Commission was held on Wednesday, 23rd inst. Present:— Sir Frederick Bramwell, Bart., D.C.L., F.R.S., Deputy-Chairman of the Commission, in the chair; Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Sir Frederiok Abel, K.C.B., F.R.S., Sir Edward Birkbeck, Bart., M.P., Michael Carteighe, R. Brudenell Carter, F.R.C.S., B. Francis Cobb, Professor James Dewar, M.A., F.R.S., Major-General J. F. D. Donnelly. C.B., James Dredge, Francis Elgar, LL.D., Sir Douglas Galton, K.C.B., D.C.L., F.R.S., Alexander B. W. Kennedy, F.R.S., Charles Malcolm Kennedy, C.B., John Biddulph Martin, Professor William Chandler Roberts-Austen, C.B., F.R.S., Sir Owen Roberts, M.A., F.S.A., with Sir Henry Trueman Wood, M.A., as secretary.

VIEW OF EXHIBITION GROUNDS.

With this week's number of the *Journal* there is issued a bird's-eye view of the Chicago Exhibition grounds, showing the general arrangement of the buildings, and the appearance of Jackson-park when viewed from the lake. Some of the details are, of course, subject to alteration, but no changes will now be made in the character of the principal buildings.

REPRESENTATION OF VICTORIA.

Lieut.-General Sir Andrew Clarke, the Acting Agent-General for Victoria, has informed the Royal Commission that it is the intention of the Victorian Government to take part in the Chicago Exhibition. The appointment of a Commission is now under consideration; in the meantime, the Government has expressed its willingness to provide a sum of £15,000, provided the exhibitors will contribute £5,000 to a total expenditure no exceeding £20,000.

APPLICATIONS FOR SPACE IN THE BRITISH SECTION.

Intending exhibitors are reminded that applications for space must be made immediately, as the allotment of space is now proceeding. Most of the available space is now occupied, and no time should therefore be lost by manufacturers desiring to be represented.

All applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, and addressed to the Secretary, as above.

Proceedings of the Society.

FOREIGN & COLONIAL SECTION.

Tuesday, March 15, 1892: Clements R. Markham, C.B., F.R.S., in the chair.

The paper read was—

PERU: ITS COMMERCE AND RESOURCES.

By F. A. Pezet.

The history of Peru is a subject which has more than once been brought before the

English-speaking world by authorised persons. Everybody at this advanced age knows perfectly well how Peru was discovered and conquered by the Spaniards, and how, after nearly three centuries of oppression, the country threw off the Spanish yoke, and established itself as an independent republic. In the brief space of time which I have at my command, I will not tire you with reminiscences of an historical nature; my object in appearing before you here to-day is, to try and interest you on behalf of my country. I come to you not as a Peruvian, to praise or advertise Peru, but as a friend of England and Englishmen; to prove that Peru is really what the many and learned historians, geographers, travellers, and writers in general have represented it to be—a country of great natural resources, with every possible condition to attain a commanding position amongst the nations of the world.

On the past riches of Peru I need not detain you. Guano and nitrate; these two words speak volumes, and can be considered as synonyms of wealth. I want to bring you to realise the present condition of the country, and its prospects for the future. Here we have a large country covering a surface of about 500,000 square miles, with a scanty and scattered population of 3,000,000 inhabitants. The last official census of Peru was made in 1876, and the returns showed a population of 2,699,945 inhabitants. But this figure is below the real number, as it has been ascertained that the Census Commission did not take into account the savage and semi-savage tribes of the mountain regions, and that, in some places of the interior, their work was very difficult through the ignorance of the people respecting the formation of the census, it being generally believed that the information required was for the purposes of taxation, a thing which the Indian greatly dreads. Although it is very difficult, if not impossible, to make a correct statement as to the uncivilised population of Peru, yet I consider that 350,000 would not be an exaggerated figure. Making allowances for the natural increase since 1876, and also for the decrease in consequence of the war with Chile, I will put down the absolute population of Peru to-day at about 3,000,000 inhabitants.

The aboriginal or Indian race which populated the country, to the extent of some 12,000,000 souls, when the Spaniards conquered Peru, still holds its own, although it has to a great extent degenerated through the miseries which, during centuries, it endured at the hands of its conquerors. The Indian race represents to-day about 57 per cent. of the entire population. In the interior of Peru it has kept in many places quite pure, not having mixed with any of the other races which have been brought into the country. There are tribes existing to-day with the old Incasic Indian features and characteristics quite distinct, and among these people there is a great and natural intellect. The other great race is the European or white, imported from Spain at the time of the conquest, and which has been ever on the increase since then. It represents to-day about 20 per cent. of the population, and is spread over the whole country in general, but specially on the coast.

As the Peruvian Indian was made to slave at the mines for his Spanish master, the Spaniards had to introduce Africans into Peru in order to till the ground and work on the cotton and sugar estates along the coast, and thus it was that the black race was brought into the country. Slavery having been abolished in Peru, in 1854, no more Africans have since come into the country, so the race has confined itself to some of the agricultural districts, and is now rapidly dying out. In its place there are the "mestizo" and "zambo" cross-breeds of blacks with whites and with Indians. The cross-breed of whites with Indians has produced the "cholo" race, which of all the castes is to-day the most numerous. These mixed races represent about 23 per cent. of the entire population, together with some 50,000 Chinese imported into the country since 1854, as agricultural labourers. The greater part of these have settled for good, and not a few of them have embraced the Christian faith and married with Indians, Cholas, Zambas, Mestízas, blacks and whites, thereby forming a diversity of new castes.

This immense country contains rich agricultural and pastoral lands, abundant mining wealth, vast petroleum fields, virgin forests, with every description and variety of timber. Its climate is as good as its soil is luxuriant.

The arid coast, the mountain ranges, and the fertile plains of the east have each a different climate, and in each region the European can find the temperature of his choice. The heat is never too excessive or lasting, and the cold can always be more or less avoided. The reports of the different Commissions which within the last two years have visited Peru, agree all on one point, and that is that the

country is admirably suited for European immigration on a large scale.

And here I come to the first and most important question for the development of Peru—immigration. Peru requires, and must have, not only skilled labour, but, above all, agricultural labourers. If the wealth of the country is to be turned to account, capitalists must make up their minds that their first step must be towards promoting an emigration current into Peru.

I do not intend to say that Peru in preference to any other country should be favoured by European emigration, no; but what I do insist upon is that Peru, on account of its great natural wealth, and its climate, offers a greater inducement to European settlers than perhaps any other South American country. In order to have an exact idea as to this, I will beg you to follow me on the map of Peru (kindly lent by the Peruvian Corporation, Limited). As you can see, Peru is situated between parallels 3° and 19° S. latitude, and between 68° and 81°, 20′ 45″ W. longitude. The exact boundary lines of Peru are not yet thoroughly defined, and this question is still the subject of international controversy, although the various Governments of the neighbouring States, as likewise that of Peru, are all agreed upon the necessity of arriving at a final settlement.

The country is divided into five distinct zones, which are formed by the two Cordilleras or chain of mountains nearly parallel to each other which traverse Peru from south to north. The coast, called *la costa,* is the zone which lies between the western chain, called Cordillera de la Costa, and the Pacific ocean; it is formed by an inclined plane from 30 to 60 miles in breadth, composed chiefly of sandy deserts, nearly destitute of vegetation, with several valleys, through which small streams run into the Pacific, affording the means of irrigation, as, on these sandy plains—in fact, over all this zone—it seldom rains.

La Sierra, or second zone, is the country which lies at a height of from 4,500 to 9,000 feet above the level of the sea. It commences on the western slope of the coast range, and also comprises all the country between both great chains. Its width varies from 60 to 120 miles. The chief characteristic of this zone is its temperate climate. Rain falls in great abundance during six months of the year—from October to April—but, notwithstanding this, the seasons, summer and winter, are the same as on the coast, with this difference, that the little rain and mist characteristic of the coast is only to be seen between May and September.

La Puna is the name given to the third zone, which many geographers consider part of the Sierra. The Puna is virtually the high tablelands or plateaus of the Andes, at a height of from 10,000 to 14,000 feet above sea level. Lake Titicaca, situated at 13,000 feet above the level of the sea, is one of the characteristics of this zone.

Cordillera is the zone formed by the mountain peaks of the Andes. It is perpetually covered by snow, but has patches here and there, where a kind of pasture grows, on which the vicunas and alpacas feed. Both the Cordillera and La Puna might well be comprised in the Sierra; but, as Professor Raymondi, Peru's great geographer and traveller, sets them up as distinct and separate zones, I have thought it wise to follow his plan.

La Montana, or Region de los Bosques—"Forest Region"—is all the country which, commencing on the eastern slope of the Cordillera, extends far away eastwards to the banks of the great rivers Amazon, Ucayali, Maranon, Pancartambo, Madera, and beyond them into Brazil. Each of these zones having special characteristics, it is easy to see that they must have great diversity of climate, and that their resources in the vegetable, mineral, and animal kingdoms must be as varied as they are profuse.

As already mentioned, in the Costa it seldom rains, specially in the northern extremity in the Department of Piura. The explanation of this phenomenon appears to be that the prevailing easterly winds, supposed to be a continuation of the south-east trade-winds, blowing across the continent, bring the clouds to the higher ranges of the Andes, by which they are broken, and the rain falls before reaching the coast. In Lima, the thermometer has never been seen below 60° at noon, and very seldom above 80°. The coolness that pervades the coast of this tropical region can be attributable to its snow-capped mountains, but is rather the effect of a thick mist called *garúa,* which covers, at times, the disc of the sun, and is partly owing to a cold current that flows northward from the Straits of Magellan to Cape Parinas. The difference between the ordinary temperature of the ocean in these latitudes, and that of the currents, is, according to Humboldt, at least 9°. In all this zone the sun is scarcely ever hidden by clouds for a day throughout the whole year, and the cool south-east breezes temper the heat of the sun

Walker & Boutall sc.

to such an extent as to make this region most habitable to Europeans.

The high plateaus of the Andes and the whole of the region which constitutes the Sierra contain, according to various travellers, among the most salubrious spots in the globe. The clearness of the sky and the purity of the air has made the Peruvian Sierra the great health resort of the Southern Continent.

The Montana has two distinct seasons—the dry season, from May to October, and the rainy season, from November to April. During the dry season, the heat is greater than in any other part of Peru. The mean annual temperature of the Amazon valley, from Manaos to Tabatinga, is 80°. Moyobamba, which stands 2,700 feet above the sea, has a mean annual temperature of 77°. Chachapoyas, situated 7,600 feet above the sea-level, has a temperature ranging from 40° to 70°. Although the Montana is traversed by a great many rivers, and the greater part of its virgin woods have not been explored, still the climate has been most favourable to the foreigners who have settled there and travelled through this region. The few cases of malaria and such fevers as are always associated with rivers, swampy forests, and uncultivated lands being almost confined to the smaller rivers, and quite rare on the banks of the Amazon, Maranon, Perene, Ucayali, and Palcazu.
